There cannot be a doubt that the repulsive power of all molecules resides in the caloric by which they are surrounded, as Metcalfe so admirably shows, and as Dr. Snow takes occasion also to opine. Take away caloric from any substance, and its molecules no longer repel each other, but, on the contrary, fall together, and form a mass, compact and dense in proportion to the quantity of caloric extracted. But as the extraction of caloric is limited, it follows that the molecules of every body in nature are mutually repulsive in a greater or less degree, as they are surrounded with greater or smaller quantities of caloric. Still more, there is every required proof that the mutual attraction of every molecule of matter for another molecule becomes lessened in direct ratio to the square of the distance. The further, therefore, that the molecules of oxygen are removed from each other, whether by dilution in caloric, or in some form of matter for which they have little affinity, or by a vacuum, their mutual attraction for each other diminishes; and, to a certain degree of extension, their attraction for the molecules of other bodies with which they may be thrown into contact, and for which they have an affinity, increases. Now if a piece of iron wire is made red-hot in the atmosphere, i. e., in diluted oxygen, the radiation of heat from the wire expands the gaseous medium by which it is surrounded, and dilutes the oxygen to such an extent, that the union of the two is prevented almost entirely, from actual absence of oxygen; and, for the same reason, the combustion of the charcoal and the taper in atmospheric air is moderate in amount; but when the burning or fused material is dipped in pure oxygen, the caloric evolved rarefies the gas sufficiently to destroy its molecular attraction, but not to such an extent as to drive it off almost altogether; and hence a rapid combination between oxygen and iron ensues. And for the same reason, if by rarefaction, by the air-pump, by caloric, or by such a gas as nitrogen, oxygen is moderately diluted, phosphorus will combine with it; although in the pure oxygen, where the molecular attraction of the gas is unbroken, no combination will take place.

If, then, these views are correct, it follows that the first four experimental facts, adduced by Dr. Snow, do not in any way show that nitrogen exerts a counter-affinity over oxygen, except in so far as it acts as a mere diluent of oxygen.

We have ventured on putting forward this hypothetical explanation of two very singular chemical phenomena, believing that it affords a fair solution of the difficulty involved; and without wishing in any way to deny the hypothesis of “counter-affinities” in reference to other chemical phenomena.

We do not always approve of the analogical reasonings of Dr. Snow. It is Campbell, if we remember rightly, who remarks that “analogical evidence is but a feeble support, and is seldom honoured with the name of proof. It is the defensive, not the offensive, weapon of the orator.” This is very true. Analogies are apt to deceive speaker and listener, writer and reader. Sometimes, again, they are seized upon hastily by the writer, and lose their effect on the reader. In page 4, our author offers an analogy betwixt the increased force which an ordinary body obtains in falling from a height, and the continuance and extension of those changes which result from attraction at insensible distances. Such an analogy is, we think, far-fetched, and quite unnecessary for elucidating the subject in hand.

In alluding a second time to vital action, the orator observes, "that the most characteristic property of vital actions probably is, that they are always caused by similar processes which have preceded them, whilst all other molecular changes may arise occasionally at least from other causes." (p. 6.) There is no ground for this distinction. Dr. Snow does not fall into an error, as many do, of supposing that one living cell generates *per se*, i. e., unconditionally, another or second cell, and that organic matter is thus made up of self-generating cells; but at the same time he does not illustrate the independent origin of each cell in a clear manner, and he attaches to these formations a higher degree of importance as phenomena, than he does to other natural formations. This is not faithful philosophy. Let there be given certain required elements and conditions in the infinite space, and there shall be formed, by virtue of immutable laws, a world, worlds, or even a system of worlds, according to the amount of the elements and conditions supplied; and these worlds not square worlds, not hexagonal, but round, like other worlds—casts, we had almost said, of one mould.

Let there be given, in the laboratory, certain elements and conditions, and there shall be formed, by virtue of laws also immutable, a crystal, and a crystal only of one kind or shape, however often produced. Lastly, let there be brought together, either in the laboratory of the chemist, or in the laboratory of nature, certain conditions and elements, and a cell will be the necessary result. But as the first cell ever formed must have been formed independently of any other cell, and as the formation of the second, or second trillionth cell, is but a repetition of the first, it follows that the production of every cell is quite conditional and quite independent of any previous cell, the proximity of cells being a secondary and mechanical arrangement, intended for the generation of a mass, and having no more to do with the origin of the cell itself, than the aggregation of the atoms of matter has to do with the origin of atoms. We are quite aware that this view of the subject is not adapted for every mind: we believe, however, in its correctness, and must proclaim it at all hazards. We know that the formation of one cell within the other, and other parts of the cell-producing process, may lead, and that right readily, to the idea that cell propagates cell; but much more powerful is the evidence in favour of the opposite opinion. The writer we are now following assists us here, indeed, by showing that an absence of certain external conditions leads to a suspension of cell-formation: "The process of change," he observes, "may, as in certain insects and plants, be suspended for a time, on account of the deficiency of warmth, of moisture, or of oxygen; but, when it recommences, it is in precisely the materials in which it left off." And, a little further on, he illustrates that the same suspension of continuous changes may occur, in other instances, out of the circle of moving things: "For instance," he explains, "if a seam of coal is on fire at a great depth from the surface, the combustion can be entirely arrested by cutting off the access of air; but, if no means are taken to cool the lately-burning materials, they may remain for months at a bright red heat, ready to enter again on the process of combustion, should air be accidentally admitted."

Our author has not yet done with the vital process; it is with him, as with all men of philosophic mind, an important subject,—a subject which is not to be looked at through smoked glasses, as astronomers look at the sun, nor to be passed over as a solemn mystery; but one which requires, as the Central Americans would say, "to be looked right down into". On the seventh and eighth pages the following remarkable passage occurs:—

"There is no distinct line of demarcation between vital processes and those that are not vital. Vinous fermentation, for instance, has been generally looked upon as a merely chemical change; yet it has great claims to be entitled a vital process. It is always accompanied by the formation of the cells or sporules of the yeast fungus—the decomposition of the sugar into alcohol and carbonic acid bearing a direct relation to the quantity of yeast produced. Many persons would doubtless say that

the formation of the sporules is a vital process, and the production of alcohol and carbonic acid a chemical process inseparable from it. According to this view, whilst cell development is undoubtedly a vital process, digestion and the formation of compounds to be secreted or excreted are chemical processes. There is no objection to such a distribution of terms, but it must be remembered that the decomposition of sugar into alcohol and carbonic acid is as closely connected with a process of organization as are the sensibility and contractility of animal tissues. This blending together of what we call vital and what we call chemical, need not surprise us, however, when we consider that all changes of composition, with their attendant phenomena, whether taking place within the living body or not, are alike the result of the attraction or affinity which exists amongst the ultimate atoms or molecules of matter."

We are bound to look upon this passage as highly unsatisfactory in its points of argument; nay, it is not made up of true and clear ideas. Take the illustration of vinous fermentation. It is admitted that certain matters and conditions being brought together, certain results will ensue; that three new substances or products will be formed, viz. sporules of yeast-fungus, carbonic acid, and alcohol; and it is said that the decomposition of the sugar into alcohol, bears a direct relation to the quantity of yeast produced. This is, of course, true; but not the whole truth, nor does it make the sporule of primary importance. The alcohol, the carbonic acid, and the sporule, are all products, as Schleiden opines, and their relation to each other may be varied as often as there can be variations in three bodies. The carbonic acid and alcohol are formed in proportion to the yeast produced. Certainly. But are not the yeast and the alcohol formed in proportion to the quantity of carbonic acid produced? and is not the alcohol formed in proportion to the amount of yeast and carbonic acid produced? In truth, these changes admit of no abstract analysis. Effects may be watched, and some results captured, and, to the eye of the superficial observer, a cause and an effect may be evident; but the candid philosopher sees less clearly, and in the process of vinous fermentation, as in other similar processes, cannot place either the one or the other product first or last.

The truth of our statements is confirmed, indeed, by the orator's own observation, "that all changes of composition are alike the result of the attraction or affinity which exists amongst the ultimate atoms or molecules of matter".

The diminution of molecular action, without actual extinction of the process, the connexions or similarities of some organized materials, and the resuscitation of suspended molecular changes, under certain circumstances, are discussed at great length by Dr. Snow, and are aptly made to precede the observations he is anxious to introduce on the subject of communicable diseases. This most important question is thus brought under notice at page 12:—

"In addition to the series of continuous molecular changes having for their result the preservation of the individual and the species, there are others, occurring in living beings, which have an opposite tendency; they divert part of the substance of the individual from the actions which are natural to the species to another kind of action, in consequence of which this substance is employed in the multiplication and increase of the materies morbi of communicable diseases—an extensive group of maladies, each case of which is caused by some material that, as a general rule, has been produced in the system of another individual. The origin of these diseases, for aught we can tell, may be as remote as that of the beings they infest and exist on."

Dr. Snow objects to the adjective "contagious" being connected with the noun "disease", and suggests that the word "communicable" would be more accurate. We see no reason why the old word "contagious" should be discarded, by its etymology what it may, if one understood and simply meaning is attached to it,—such, for instance, as this by Adams: "Nothing can be called a contagious disease unless the person affected by it can induce a similar disease in others, whether regard to season, climate, or any local circumstances."

The following is Dr. Snow's catalogue of communicable diseases: "Syphilis, small-pox, measles, scarlet fever, &c."

typhoid and relapsing fevers, erysipelas, yellow fever, plague, cholera, dysentery, influenza, hooping-cough, mumps, scabies, and the entozoa." Many of our readers will be inclined, we doubt not, to question the propriety of including all these diseases under the head of contagious or communicable diseases; but, if the general doctrine of contagion be admitted at all, it certainly extends to the disorders specified, and might include several more, such as hydrophobia, glanders, puerperal fever, and varicella.

After again asserting the self-reproductive power of organized matters, and after making a few observations on the period of incubation of a communicable disease, our author goes the whole contagionist, and says: "One character of communicable diseases, is, that they are apt to be extremely prevalent at particular times and places. This character, which arises strictly out of their communication from individual to individual, has obtained for many of these diseases the name of epidemics."

It is exceedingly gratifying to see how ably Dr. Snow treats on the cause of the increase, at intervals of time, of the communicable diseases: "The extent of population and of intercourse," he observes, "has great influence over the epidemic character of a communicable disease. The various eruptive fevers are constantly present in London, and are only liable to fluctuations in their prevalence. In less populous districts, however, there are not enough subjects to support their constant presence. One or other of them is often absent for a number of years, and, when reintroduced, spreads to a great extent." The cholera, he thinks, "is so difficult of support that the world seems scarcely large enough for it; and, were it not for its pasture in India, it would be in danger of passing altogether out of existence, like the dodo of the Mauritius." On this last question, we can only exclaim with Hamlet—

"Tis a consummation
Devoutly to be wished."

Dr. Snow is of opinion that the communication of diseases was not recognized until a recent period. Sydenham, he says, recognized the communicability of the plague alone. In making this assertion, however, Dr. Snow has fallen into an error. It may be quite true that Sydenham did not verbally recognize any disease contagious, except what he calls the plague; but then the extended meaning of the word "plague", as it was used by Sydenham and by all the old writers, must be taken into consideration. Not a shadow of doubt is there that every epidemical disease has, over and over again, been described under that title. Sydenham himself, there is every reason to believe, considered the malignant scarlet fever as plague; indeed, so many diseases were, in the course of the fifteenth, sixteenth, seventeenth, and even eighteenth centuries, included under the name of "pestis", that we are told, in the preface to a pamphlet by Thomas Phayer, republished in 1772, of an eminent member of the faculty, who, on being asked why he did not join in the "plague dispute", said ironically, "that he had never seen the plague". Moreover, the communicability of small-pox was recognized almost universally by the ancients. The system pursued by the Turks, of inoculating for the small-pox, is of ancient date, and implies distinct knowledge, on the part of a whole nation, of the communicability of the disorder. In the Highlands of Scotland there was also a very old and prevalent custom connected with the disease now named, which deserves especial notice. When small-pox was epidemical, healthy children were put into the same bed with children that were suffering from the disease in its mildest form, in order that a mild form of the affection might be obtained. In the Arabian school, the doctrine of contagion was freely admitted; and some of the Greek physicians entertained a similar notion,—to say nothing of the historians and poets who have written to the same effect. The whole question of the ancient opinions concerning contagion has been discussed briefly, but with consummate skill, by our learned countryman, Francis Adams, in his translation of the works of Paulus Ægineta. Referring, first, to the Mosaic description of the communicability of leprosy, Adams next proves, on indis-

putable evidence, that the general doctrine of contagion was held by Thucydides, Lucretius, Ovid, Silius Italicus, Livy, Dionysius, Diodorus Siculus, Appian, Plutarch, Quintus Curtius, Dio Cassius, Eusebius, Gregory of Nyssa, Evagrius, Aristotle, Isocrates, Marcus Antonius, Virgil, Pliny, Seneca, Chrysostom, Isidorus Hispalensis, Aretæus, Galen, Cœlius Aurelianus, Aëtius, Paulus, Rhases, Haly Abbas, Avenzoar, Avicenna, and Boccaccio. Nor was it merely in regard to pestis that this opinion was held by all these writers, for Paulus and Aretæus spoke also of the contagious nature of elephantiasis. Rhases described elephantiasis, itch, consumption, pestilential fever, ophthalmia, and malignant pustules, as contagious; and Avicenna remarked that small-pox and measles were, of all diseases, the most contagious. Plato also spoke of the contagious nature of ophthalmia; and the laws of Moses with reference to lepers, and the after writings of Josephus, in comment on those laws, indicate how exceedingly old is the notion of the communication of diseases from one person to another. It would be possible to enlarge greatly on this subject by referring to the establishment of pest and lazaret-houses, to the origin of quarantine, and to many other matters. Sufficient, however, has been written to show that the old writers held the doctrine of contagion; and, if Sydenham does not describe, in words, the contagious nature of small-pox, we think his silence can only have arisen from the circumstance that the fact of the communicability of the disease was so notorious in his day, that he did not think it necessary to allude to the matter at all. We have entered deeply into this historical question, because it is of great importance to have correct views on the subject of medical literature.

In an easy and earnest style, Dr. Snow tries to throw overboard the opinion, that epidemic disorders are propagated by the agency of the atmosphere. He shows good argument, too, in refuting the idea that there is such a thing, in some persons, as an innate predisposition to disease; and he criticises unmercifully all speculations on the effects of the new principle in the atmosphere, concerning which the philosophic world is now so mystified, ozone; perhaps on this subject he is too critical. If, in truth, a peculiar principle—call it ozone, or anything else—can be produced by various processes (and no one who will put his nose near an electric machine will doubt the fact, we presume), and if this principle is always present in the atmosphere in a greater or lesser degree, as such men as Schönbein and Faraday assert, there is more in the subject than deserves to be sneezed at. However, it must be admitted that actual knowledge does not support all that has been said on the matter.

The influence of climate and season in inducing epidemic diseases, has, Dr. Snow most properly observes, been very much overrated. Locality, he imagines, has a greater influence. He does not admit that such endemic complaints as intermittent fever arise from malaria or miasmata, but offers several proofs that the drinking of impure water is a more common cause. There is great reason for accepting the position which our author here takes; and we have ourselves recently heard of an instance, occurring in the eastern counties, where several persons suffered from ague, in consequence of drinking stagnant water; the disease passing off entirely when a fresh supply of water was procured. At the same time, we think that it is going a little too far to say that "the disease of the liver and spleen, to which persons are subject after attacks of intermittent fever, also confirms the view that its material cause enters the system by the alimentary canal, and not by the lungs." (p. 25.)

It will surprise many of our readers to be told that so excellent a thinker as Dr. Snow disbelieves the common opinion, that gases arising from the decomposition of animal matter cause no fevers or other epidemical diseases. The close observer will not be so surprised at this disbelief, and will agree with Dr. Snow in believing that it is a mistake to attribute the excess of epidemic disease found in crowded and poor localities, to what are called noxious effluvia. Few, however, are there, not excepting those who believe with him in specific causes of disease, who will go so far as he does in chanting the gentle innocence of those "soft and balmy gales" which

any nature-loving traveller may find in the wynds of Glasgow, the cellars of Liverpool, or the sewers of London. Mr. Grainger, we imagine, would come to a different conclusion; and there cannot be a doubt that impure states of the atmosphere do assist most importantly, if not in the propagation of epidemical diseases, at least in favoring their rate of mortality. Dr. Snow himself indirectly admits this, indeed, a little further on, where he preaches, in powerful language, the worth of universal cleanliness.

We said a little ago, that Dr. Snow referred to those hard swellings of the spleen and liver which attend ague, in support of his notion that the seeds of this distemper were taken into the system by the digestive organs. At page 29, he uses a similar argument, and infers "that the specific cause of influenza and measles is drawn in with the breath, as these diseases chiefly affect the respiratory organs." We, with all deference, must enter a second protest against this line of argument. Neither Dr. Snow, nor any one else, can prove as yet that the affections of the lungs which attend the diseases last named are not secondary affections, arising from general systemic derangement. Nay, is it not evident that another writer might, with equal fairness, argue from appearances, and say that the poison of measles, scarlet fever, small-pox, and sweating sickness, was taken in by the skin, because in those diseases the skin is chiefly affected, just as past writers were wont to attribute diabetes to a disorder of the kidneys, because the function of those organs is peculiarly active in that disease.

Some readers may possibly not be aware of the fact that a few years since the distinguished author of the oration before us broached an ingenious and, in some respects, a novel theory, on the propagation of communicable diseases. The immortal Howard held an opinion, that the poisons of contagious diseases are only carried to very short distances by the atmosphere. Dr. Snow entertains a similar opinion, and supplies the place of that hypothesis which supposes that the poisons of the contagious diseases are drawn in with the breath, by another hypothesis, that the said poisons are taken in by the stomach—are, in truth, swallowed. Now Blackburne, in a treatise on scarlet fever, written in 1803, says that "infectious effluvia may be propagated along the olfactory nerves to the brain, or pass through the mouth into the stomach, or be gradually admitted into the circulation through the medium of the lungs"; and he then goes on to offer proofs from Drs. Lind and Johnstone, that poisonous effluvia may be taken into the stomach. Dr. Snow's hypothesis is, however, different from that of Blackburne, inasmuch as he presumes that the seeds of many diseases, but especially of the Asiatic cholera, pass off with the excretions of patients, find their way into rivers, wells, etc., are thus actually swallowed by other persons previously healthy, and finally set up disease in the healthy body that has received them.

On the present occasion, as we have previously hinted, he is anxious to extend this theory of the propagation of communicable diseases. "There is evidence," he tells us, "tending to show that typhoid fever, yellow fever, and plague, as well as cholera, are communicated by accidentally swallowing the morbid excretions of the patients, and that these latter may sometimes be conveyed to a distance with drinking water, or other articles of diet, without losing their specific properties." (p. 30.) And he then goes on to offer proofs of this opinion, which our space will not allow us to reprint. The subject deserves much consideration, and we here offer what will, we hope, be considered a fair opinion upon it.

The first question that has to be considered is, whether or not such diseases as those we have named in the course of this review, are, as Dr. Snow imagines, transferable from one person to another by means of sporules, germs, or some other form of organized matter. With reference to some of these diseases, this theory is highly probable, as in the instances of syphilis and small-pox, and although it does not seem to be applicable to some others, we are willing, for the sake of discussion, to extend it to all. This point gained, the next question is, How does a

healthy system receive the presumed organized disease-giving material?

It is impossible to suppose more than two channels by which such reception can take place: the first by inoculation, or direct transference of the morbid matter into the circulating fluids; and, secondly, by indirect transference, viz., by absorption through mucous membrane or through the skin, which is a modified form of mucous membrane. The transference of any morbid matter into the system by inoculation is so easily understood, that it requires but little comment. The possibility of transferring disease from one person to another by this means, has long been recognised as the only positive proof of the communicability of any disease; and if Dr. Snow could show that cholera might be induced by the inoculation into a healthy body of some morbid product, thrown off by a body suffering from cholera, he would establish an astounding fact, and supply convincing evidence of the correctness of his theory. In the introduction of morbid materials into the system through mucous membrane, the difficulty increases. We know that through the mucous membrane of every part of the body, and even through the skin, the act of absorption goes on—nay, we know that at a push these structures will do compensating duty for each other in a great degree. In instances where drinking water is wanted (as occurred in Bligh's voyage after the mutiny of the *Bounty*) the pangs of thirst may be relieved by surrounding the body with wet cloths; and counter instances might easily be found. But the application of this principle is not general, i.e., it does not extend to the absorption of all materials. It is possible that absorption through equal portions of the skin, or of the mucous surface of the lungs, vagina, or urethra, is not widely different in degree; but the difference betwixt absorption in the intestinal canal and in the above-named parts must be much greater, inasmuch as the substance to be absorbed will of necessity be brought into contact and commingled with the digestive fluids, and will also be altered materially in character. How far the process of digestion lessens or increases the activity of morbid matters, is as yet an open question. That it will produce modifications is evident: that it sometimes destroys the power of certain animal substances which, when otherwise absorbed, act as poisons, there can be no doubt; and that it does not prevent—nay, rather increases—the action of some other poisonous substances, there is also no doubt.

The great problem, therefore, that has to be solved is, whether the presumed organised materials which give rise to the diseases named by Dr. Snow,—namely, typhoid fever, yellow fever, plague and cholera, can pass through the process of digestion, and afterwards being received into the system, light up the peculiar classes of symptoms by which those diseases are characterised. Dr. Snow certainly does show several very curious facts in proof of the communicability of cholera by the swallowing process; and as there is no evidence to the contrary, who can say that typhoid fever, yellow fever, and plague, cannot be propagated in the same manner?

The question of the spontaneous origin of communicable diseases is very fairly discussed by Dr. Snow. He supposes that some of these diseases may arise, "so to say, spontaneously, that is, from other causes than their communication; just as ordinary combustion, putrefaction, and some other continuous molecular changes, very often commence anew, from various causes, without any continuity with previous changes of the same kind." Erysipelas is one of those diseases which Dr. Snow imagines may thus arise. The following curious instance, which occurred a few years since, under our own observation, bears in a remarkable manner on this subject:—

In a little village in Essex, two farm labourers were thrashing corn in a barn. They had arrived nearly at the end of their task; and whilst turning up some loose masses of straw that were lying amongst a considerable quantity of dust on the barn floor, they were both simultaneously seized

with sensations of nausea, and other disagreeable symptoms. They continued at their work for some time, but at last were fairly obliged to give in, and were very kindly ordered by their employer to go home, their pale, distressed faces indicating that they were really ill. We saw them a few hours afterwards; they were complaining of shiverings, had a loaded state of tongue, and pains in the back and limbs. In the course of the following day, an erysipelas bluish appeared on the face of each patient, and each passed through a most severe and dangerous attack of erysipelas of the head and face, ending in formation of pus under the scalp, and attended with extreme debility. The men recovered. There was, at the time, no other case of erysipelas in the village or immediate neighbourhood, nor did any other cases spring from these.

The remarks made by our author on universal cleanliness, as a means for preventing the propagation of epidemic diseases, have been referred to already, and are very important.

"It should not be a cleanliness," he truly observes, "for mere appearances; it should be a rational cleanliness, like that by which the chemist keeps his tests pure and distinct, and the farmer his land free from weeds. There should be not only personal cleanliness, but cleanliness in every department of the household—cleanliness in builders and owners of house property, to deter them from sinking wells so near to cesspools and drains, that their contents may percolate without proper filtration—cleanliness in water companies, to prevent them from sending water containing sewage to their customers—and cleanliness in sanitary reformers, to deter them in their fear of offensive effluvia, from abolishing cesspools and having the sewers flushed, and thus sending all the recent excrementitious matters into the rivers, until they have ascertained that people are no longer obliged to drink the water of those rivers."

These are golden maxims—maxims, the practical accomplishment of which, throughout the world, would do more to civilize our species, and increase human happiness, than all the profound eloquence, and mystic symbolism, that has been thrust on the ear and the eye of mankind, since the earliest rostrum was erected, or since the first bull was sacrificed by Egyptian priest, and with solemn pomp, on the altar of Epaphus.

Like many other epidemiologists, Dr. Snow hurls, with dexterous hand, a stone at the quarantine system. Quarantine has been held in various degrees of estimation by the medical profession. When first started in Venice in the latter part of the fifteenth century, it met with opposition from the physicians, and was suggested and carried out by the legislative mind alone. In later times, however, many medical men have spoken of its worth in the highest terms, and no one more than our own countryman, Blackburne. In this day, medical men are strongly inclined to the abolition of quarantine. Dr. Snow puts the question, as we think, in a proper light, by explaining that now, "when the commercial interest and influence preponderate over every other, the day is gone by for strict quarantine; which, indeed, was ever but a doubtful measure, as it was liable to evasion, and could not be enforced on the smuggler." (p. 36.)

We now turn over the last page of Dr. Snow's entertaining and instructive oration. Our comments have, it is true, been carried to a great length; but, as it is a rare thing to find ourselves in possession of so suggestive and important a book as the one now in our hands, we have sufficient reason for pleading an excuse. The criticisms we have felt it our duty to make have arisen out of a sincere love for earnest and truthful scientific discussion, and are submitted to our professional brethren, and to Dr. Snow especially, with all good feeling and with profound respect.

PERMANENT CURE OF REDUCIBLE HERNIA. By GEORGE HAYWARD, M.D., of Boston, Mass. Presented to the American Medical Association, May 1852. pp. 25. Philadelphia: 1852.

A COMMITTEE of the American Medical Association addressed, a few years ago, a number of questions to their professional brethren, on the best means for producing a permanent cure of reducible hernia. The book before us is the report of this committee. To the questions sent out, only seven answers were returned, and these, say the committee, "though interesting and valuable, do not throw so much light on the subject to be investigated, as they had hoped to derive from that source." Under these circumstances, the committee thought that it would render their report to the Association more worthy of consideration, to introduce into it information derived from other sources. In a brief and practical manner, therefore, the authors have collated all the recorded methods, ancient and modern, that have been employed for the permanent cure of reducible hernia.

A short abstract of the report is subjoined.

The operations that have been performed till within these last fifty years, have been of a severe character. These operations were, *cauterization, ligature, sutures, excision of a part, or of the whole, of the sac, and castration.* "The object of all of them was to obliterate or contract the neck of the sac, and thus prevent the protrusion of the abdominal viscera."

Barbarous in character, dangerous as barbarous, performed often by ignorant quacks, and even by women, these operations must have destroyed more lives than all the ruptures that have been left untouched by surgical hands since the world began. The American committee, in summing up their remarks, justly quote the saying of Mr. Lawrence, that, "since the enlarged state of the tendinous opening is not removed by the processes adopted for a radical cure, since a recurrence of the disorder is not prevented, we may assert that these operations do not afford any greater chance of relief than the employment of a truss."

The committee also direct attention to the following modern operations for the radical cure of hernia: 1. Closing the neck of the sac, by leaving a piece of omentum in the inguinal canal, and by forcing the testicle into it, and then bringing on inflammation by incision, so as to cause effusion of fibrine; 2. Closing the external ring and the canal by means of the hernial sac, as performed by Petit and Garengot; 3. Gerdy's method of crowding the integuments into the inguinal canal, and removing the cuticle from them by caustic alkali; 4. Balma's operation of introducing gold-beater's skin and gelatine into the upper part of the hernial sac, so as to induce inflammation; 5. An autoplasmic operation by Dr. Jamieson; 6. Graefe's barbarous plan of cutting out a piece of the sac, and then introducing a piece of lint, besmeared with stimulating ointment, into the inguinal canal; 7. The seton; 8. Bonnet's system of passing pins through the neck of the sac, and Mayor's modification of needles for pins; 9. Acupuncture; 10. Subcutaneous scarification of the neck of the sac (Guerin), and scarification of the inguinal canal (Velpeau); 11. The operation by injection; by laying open the sac (Velpeau); by the subcutaneous method (Dr. Pancoast); 12. Scarification of the ring; 13. Closing the ring with sutures, as proposed by Dr. Thomas Wood of Cincinnati.

The committee offer several remarks on these operations. They relate a very instructive case, in which strangulated enterocele succeeded upon what was supposed to be a radical cure from a closure of the canal with omentum. They describe Dr. Pancoast's operation by injection:—

"The hernial sac, its contents having been previously returned, was punctured with a small trocar passed through a canula. Having ascertained that the instrument was fairly in the sac, by the freedom with which it could be moved about, the point of it was then directed upwards, so as to scarify the internal surface of the upper part of the sac. The trocar was then withdrawn, and half a drachm of the tincture of iodine, or an equal quantity of tincture of cantharides, was thrown in

slowly by means of a small syringe fixed to the canula. The canula was then withdrawn, and a compress was applied just above the external ring; and the pad of the truss which had been put on before the operation, was brought down over the compress."

We shall be anxious to learn what will be the success of Dr. Wood's operation, that, viz. of closing the ring with a suture. Dr. Wood admits that his experience is at present too limited to warrant him in saying much in its favour. He seems, however, to have great hopes as to its ultimate success. The committee do not describe the operation, but inform their readers that an account of it may be found in the last volume of the *Transactions of the American Medical Association*.

The committee close their report by offering the following opinions.

"I. That there is no surgical operation at present known, which can be relied on with confidence to produce in all instances, or even in a large proportion of cases, a radical cure of reducible hernia.

"II. That they regard the operation of injection by the subcutaneous method as the safest and best. This will probably in some cases produce a permanent cure, and in many others will afford great relief.

"III. That compression, when properly employed, is, in the present state of our knowledge, the most likely means of effecting a radical cure in the greatest number of cases." (p. 20.)

Three letters by Drs. J. M. Warren, Parkman, and H. J. Bigelow, are added as an appendix, but these letters contain nothing novel, although very nicely written.

From the remarks and extracts which we have supplied, our readers will see that their attention has been directed to a most valuable and practical pamphlet, and will probably join with us in returning our best thanks to Dr. Hayward and his colleagues for their labours; labours which may be continued at some future day with infinite advantage to the science of surgery.

THE MEDICINAL SPRINGS OF HARROWGATE. By GEORGE KENNION, M.D. 16mo. pp. 31. London: 1853.

THE author informs us in his preface, that his "pages are not intended as a 'Guide to the Harrowgate Waters', nor as a 'Hand-book to the locality'; and still less as a 'Watering-place puff'." This, we think, is a correct estimate of the work.

The fresh and bracing air of Harrowgate makes it a suitable residence for certain classes of invalids; and its mineral waters are of undoubted efficacy in many diseases. From the stimulating and aperient properties which some of them possess, they are often of great advantage in the complaints of advanced life, attended with debility and impurity of the blood from imperfect elimination of effete matter. Patients suffering from gout and chronic rheumatism are often cured by their judicious use. It must be borne in mind, however, that there are at least forty different springs in Harrowgate, varying considerably from each other. Dr. KENNION places them in four groups, viz.:

1. Strong sulphureous waters.
2. Mild sulphureous waters, with alkaline impregnations.
3. Saline chalybeate waters.
4. Pure chalybeate waters.

Dr. Kennion mentions the popular error which considers sulphureous waters as universally applicable to the treatment of skin-diseases, as a frequent cause of disappointment to those who resort to Harrowgate. As these affections are distinct in their origin, so are they amenable to remedies distinct and different from each other. The improper use of mineral waters is a well known source of dangerous and even fatal consequences; still, the following caution is worth quoting.

"The waters of Harrowgate are," he says, "powerful for good, but no less productive of evil, when improperly taken. No year unfortunately passes without carrying off some victims to their own imprudence, who, in the hope of more speedy benefit, take large and unmeasured supplies, and thus precipitate the fate which they were only too anxious to avert. A

very short time has elapsed since this occurred to a most gallant and distinguished officer. He came here to drink the waters for some slight complaint, and in the course of two or three days, he drank a quantity which ought to have been the supply for as many weeks. The effect was to produce an apopleptic seizure, which rapidly proved fatal." (pp. 18-19.)

Dr. Kennion's tract may be described as a very condensed, and yet an instructive, account of the general and specific characters of the different waters of Harrowgate.

PERISCOPIC REVIEW.

MICROSCOPICAL DISCOVERY.

THE DEVELOPMENT OF THE TEETH.

A very interesting paper on this subject has appeared in the third number of the *Journal of Microscopical Science*, p. 149, from the pen of Mr. T. H. HUXLEY. Our readers are doubtless aware that the dentine, or proper substance of the tooth, is usually supposed to be formed by ossification of the cells of the pre-existing pulp, and consequently by layers added *within*; while the enamel is considered to be superimposed on it *from without* by a secreting layer, the "enamel organ", folded over the crown of the tooth. This account Mr. Huxley contradicts; the main object of his paper being to prove that the dentine is formed, not by ossification of the pulp, but rather by a process of deposition in, or on its outer layer, and that the supposed "enamel organ" has no function such as that attributed to it, the enamel being separated from it by a membrane (the persistent capsule of Nasmyth) and formed, in some manner not yet explained, on the surface of the crown of the tooth. An analogue of this he finds in the dermic bones of the skate, where there is distinct enamel, and no "enamel organ" whatever; and he brings out the fact by actual observation of the teeth of man.

If a young tooth capsule be opened, it will always be found that a space filled with fluid exists between the inner surface of the capsule and the outer surface of the pulp. The two are perfectly free from all adherence to one another; the only substance between them, besides the fluid, being a more or less abundant whitish matter, which sometimes adheres to the one and sometimes to the other. If the tooth be very young, a structureless membrane may be traced over the whole surface of the pulp; and it is not at all difficult to trace this in perfect continuity on the inner surface of the walls of the capsule.

The whitish substance, just mentioned as lying in the closed sac formed by the membrane so reflected, is delicate, friable, composed of cells, and, in short, is plainly the altered epithelium of the reflected membrane: it is this layer of epithelium which has been dignified with the name of "enamel organ", and invested with the function of secreting or forming the enamel.

Mr. Huxley next proceeds to inquire into the relation of the dental tissues to the tooth-capsule.

If a very young tooth, say from a foetus of the seventh month, be carefully examined, especially after the addition of acetic acid, under the microscope, the thin cap of tooth-substance may be seen to be everywhere covered by a very delicate membrane, evidently continuous with the reflected capsule described above; and the enamel fibres can be distinctly seen *under* this delicate membrane; making it of course obvious, that the so-called enamel organ, being *above* the membrane, can have no such function as that attributed to it. Between the dentine and enamel no trace of membrane can be found.

The next question examined into is that to which we have already alluded—the exact mode of formation of the tooth substance from the tooth-pulp.

The dental substance, our author holds, is not formed by simple ossification of the cells of the pulp (Nasmyth), but is deposited within the pulp in definite masses, the gaps between which eventually constitute the dental fibres, *parenchymate materiam suppeditante* (Raschkow.)

When the ossifying boundary of a tooth-pulp is examined, it is seen that where dentification has not begun, the membrane so often mentioned is in immediate contact with the substance of the pulp, which is composed of a homogeneous transparent base, in which closely arranged nuclei are imbedded. Passing towards the ossifying edge, we see in the profile view a clear, more strongly refracting layer, gradually increasing in thickness, which begins to separate the proper substance of the pulp

from the investing membrane, and is the young dentine, as transparent as glass, and at first quite structureless in appearance. No trace of "nuclei" can be seen in it; the bodies which have been described as such being, according to Mr. Huxley, simply lacunæ, and being afterwards found to form the canals of the dentine. He "believes that these facts afford sufficient demonstration that the pulp is *not* converted directly into the dentine; and that the structure of the latter does not depend upon the calcification of pre-existing elements."

In a morphological point of view, the relations of the *cement* show it to be homologous with the enamel. In a very beautiful section of a human tooth from Mr. Busk's cabinet, the upper portion of the cement exhibits in places a very distinct transverse striation, resembling its perfect enamel; and in the tooth of a young calf the transition of the one structure into the other was well shown. The enamel and the cement, therefore, according to Mr. Huxley, are formed on the surface of the dentine, not by the "enamel organ", but in some way which he does not explain. Is it not possible, that not the epithelium, but the very membrane itself, is the agent?

In conclusion: the tooth-pulp being a protrusion of the dermic tissue of the gum, and the capsule an involution of the same, the reflected membrane is the analogue of the basement membrane of the mucous lining of the mouth, and the "enamel organ" merely its epithelium, inclosed in the sac formed by the involution of the capsule.

The teeth, therefore, are, true dermic structures, and are analogous to the hairs.

THE TRANSMISSION OF ENTOZOA.

M. HERBST (*Annales des Sciences Naturelles*, xvii, 63), in dissecting a badger, found its voluntary muscles full of the minute and curious parasite called trichina. This, as our readers are probably aware, is a minute vermiculus coiled up within an oval semicartilaginous cyst, about one-twentieth of an inch in length. With the flesh of this badger he fed three puppies, about six weeks old; and on killing them some time afterwards he found the voluntary muscles of all of them full of trichinæ. Now, as these worms are not common, there can be no doubt that their presence in the three dogs in question was owing to their having eaten the flesh of the badger. How the parasites passed into the circulation, and reached the muscles, the author does not attempt to decide; but the fact which he records is a most interesting one, and highly important as a contribution to the history of entozoa.

CAPILLARIES OF THE LIVER.

Mr. RAINY writes to the editor of the *Journal of Microscopical Science*, p. 231, as follows:

"In the last part of Todd and Bowman's *Physiological Anatomy*, a doubt is expressed concerning the nature of the ultimate passages through which the blood circulates in the liver. Whether the smallest bloodvessels of this organ are true capillaries; that is, are possessed of a single tunic like other vessels of this description, or whether the blood passes along mere spaces or channels formed by the hepatic corpuscles, so as to be in actual contact with their cell-walls, is regarded by these authors as a question yet to be decided.

"Having at this time in my possession a portion of injected human liver, in which I have no difficulty in showing the smallest capillaries, and in demonstrating their tunic, the following observations will, I hope, be considered worthy of a place in your valuable Journal; first, because any doubt proceeding from such high authorities cannot fail to unsettle a point of minute anatomy which the microscope has satisfactorily established; and secondly, because the supposed fact of mere blood-channels existing in the liver, whilst true capillaries are demonstrable in other glands, seems to depart too widely from a general law to have even the sanction of probability in its favour.

"The examination necessary to show the capillaries of the liver is best made on a very thin slice of injected liver, taken from a part where the injection begins to fail; but, before examining this section, it must have been submitted to a gentle current of water, in order that the biliary corpuscles may be entirely washed away from the meshes of those capillaries which project from the thinnest part of it.

"In respect to their structure, these capillaries differ but little from those of other parts. Their calibre in the liver I have always observed to be very unequal, arising most probably from the manner in which they are compressed by the corpuscles which lie in immediate contact with their walls, and fill up the areolæ produced by their numberless inoculations. Their

average diameter is about 1-3000th part of an inch. Their tunic is remarkably thin and transparent. The meshes are generally circular or oval, and about 1-1000th of an inch in diameter.

"The difficulty of displaying the capillaries of the liver I believe to arise from the close connexion of the hepatic corpuscles with their walls, (there being in this organ no visible basement membrane), and the extreme fragility of the latter; so that the means employed to remove the corpuscles from the meshes of the capillaries will break away the vessels also. This, I think, will not be so likely to take place if the part have been kept a few days before being examined, and be treated in the manner above described."

PRACTICE OF MEDICINE AND PATHOLOGY.

INTESTINAL OBSTRUCTION FROM TRANSPPOSITION OF STOMACH AND DUODENUM: CONCEALMENT OF COLON BEHIND THE DUODENUM.

In the *American Journal of the Medical Sciences* for April 1853, Dr. DAVID PRINCE relates the case of a little girl, aged 6 years, who had been through life subject to slight colic. On January 30th, she was attacked with pain in the abdomen, which gradually increased, and was attended with tenderness on pressure, and with vomiting. She died early on the morning of the 31st.

On *post-mortem* examination, the following appearances were discovered.

The ascending ramus of the colon was of a chocolate colour and greatly distended, with its cæcal extremity in the left iliac region, and free, the mesocolon allowing it as much freedom of position as any loop of small intestine. About a pint of brown serum was removed from the cavity of the peritoneum, and some flocculi of coagulable lymph were seen, but no adhesions. The parietal peritoneum presented everywhere numerous minute points of arterial congestion, in contrast with the dark hue of the intestines. The rectum, and sigmoid flexure, and descending colon were collapsed and pale, but the transverse colon did not at once appear. The stomach, of its natural hue, and collapsed, was found reversed, the large or cardiac extremity being on the right side under the large lobe of the liver, and the small or pyloric extremity pointing to the left. The head of the pancreas rose from its ordinary confined position to meet the duodenum, which pursued its course to the right, passing *anterior* to the colon, and closely binding it down, and acquiring the usual length of mesentery as it became jejunum. The mesenteric artery, with the accompanying veins and nerves, passed by the side of the duodenum anterior to the colon, causing a permanent encroachment upon the colon for the space of an inch and a half; so that, upon being released from this congenital confinement, the canal would only admit the passage of the middle finger. The valvular structure characteristic of the colon was here absent, the mucous membrane presenting a smooth surface. Upon relieving this natural stricture, the contents of the ascending ramus passed freely into the hitherto collapsed portion. The line of demarcation between the inflamed and uninfamed parts was as distinct on the cæcal side of this stricture as if a ribbon had been tied around the intestine, and the ascending ramus painted up to this band. No substance was found within the intestine capable of causing the obstruction.

CASE OF STRANGULATION OF THE SMALL INTESTINE BY A DIVERTICULUM OF THE ILEUM.

Dr. SAMUEL GORDON relates the following case in the *Dublin Quarterly Journal of Medical Science* for May 1853.

CASE. A powerful, tall, muscular labourer, aged 46, was admitted into the Whitworth Hospital, in Dublin, on February 20th, 1853. He lay with his knees drawn up, and his head and shoulders slightly raised. The face had a livid pallor; the countenance was depressed, but very anxious; the eyes sunken and dull, surrounded with a bluish circle; the intellect and sensorial faculties perfect. The pulse was 132, small and compressible; the hands were cold and blue. The abdomen was very tense; the lower part had a doughy feel, but without fluctuation; the upper part was tympanitic. There was no pain, except on deep pressure; and it was confined to the right iliac region and the umbilicus; it was a dragging sensation rather than pain, and was increased by motion. He had also obstinate constipation, with tenesmus, and constant vomiting of yellow fecal matter.

His bowels had been moved freely on Feb. 13th, but not on the 14th, on which night he was attacked with a gradual swelling or increasing sense of fullness spreading through the abdomen. On the 16th he was attacked with vomiting, at first very bitter; on the following night it assumed the characters of yellow colour, feculent odour, and most disgusting taste. He had had no evacuation *per anum*, except some which was described as like the droppings of a hare.

The diagnosis formed was, that there was peritoneal inflammation from intussusception or some other obstruction of the intestinal canal.

He was ordered to take every two hours a pill containing nearly gr. iv. of calomel and one-sixteenth of a grain of opium; to have warm and stimulating fomentations constantly applied to the abdomen, and occasional enemata of warm water to obviate the tenesmus. Small doses of warm wine and water were also directed to be administered.

The following day the vomiting was relieved; the pain on pressure over the abdomen was not increased; his brother, who remained with him, said that he had passed from his bowels a "soft substance like a piece of gut". This, however, could not be seen by Dr. Gordon: and he suspects that there must have been some error. It reminded him, however, of the preparation placed by Sir A. Cooper in the museum of Guy's Hospital, in which, in a case of intussusception, coagulable lymph was effused, forming an accurate mould of the intestines; and also of those cases of intussusception, in which the invaginated portion had sloughed away, leaving the canal of the intestine pervious. The only complaint which he made on this day was of tightness of the chest and difficulty of breathing—of which he had before complained. The remission of the symptoms was not of long duration; for he died not many hours after the morning visit.

EXAMINATION OF THE BODY. Part of the small intestine was much distended and vascular; while in the right iliac fossa was another portion perfectly collapsed, not thicker than the intestine of an infant, and of various shades of colour from a dark purple to a light red. There was no soft lymph or purulent matter in the peritoneum; the serous membrane was vascular, in some parts seeming almost gangrenous; it was also remarkably dry, and in several places had a punctated appearance. The intestines were in some places very slightly agglutinated. A large portion of small intestine was strangulated by a diverticulum, which came off from the ileum about eighteen inches from the cæcum, opposite the attachment of the mesentery, being large enough at the commencement to admit the middle finger. It immediately turned over the ileum; and first passing in front of a large loop of intestine and corresponding mesentery, encircled it near its juncture with the cæcum, appearing to press most on the mesentery. It then again closely constricted the ileum about five inches from where the diverticulum was given off, and passed upwards and forwards, to be united by strong membranous bands to the anterior wall of the abdomen at about the juncture of the right iliac and hypogastric regions. The lower portion of intestine which was constricted contained only mucus; the internal coat was much congested, and the lower part was of a very deep colour. The diverticulum was seven inches and a half long; it was very narrow in the centre, and again dilated at the termination; it contained only mucus. The mucous membrane of the stomach was softened, and presented several minute bloody spots; it contained much thin slimy mucus. The distended portion of small intestine contained yellow fecal matter, like that which had been vomited during life. The collapsed portion was perfectly empty. The large intestines were greatly reduced in size, and contained a small quantity of hard scybala.

The lungs presented interlobular emphysema. The mucous membrane and other portions of the bronchial tubes were perfectly healthy.

REMARKS. Dr. Gordon observes that the evidence of peritonitis in death from internal strangulation are very inconstant; being in some cases, as in the present instance, very imperfectly developed; while, in other cases, the intestines have been found matted together with lymph. The amount of peritoneal inflammation does not appear to be connected with the condition of the stricture, nor with the age or strength of the patient. It generally commences at the stricture; but sometimes is entirely wanting at this point, although there may be distinct evidences of most acute inflammation in the rest of the abdomen.

ASSOCIATION INTELLIGENCE.

MEDICAL REFORM COMMITTEE OF THE METROPOLITAN COUNTIES BRANCH.

The Committee met on Friday last, Dr. SEMPLE in the Chair. The following gentlemen were present.

Dr. Snow Beck.	Dr. Fraser.
J. Bowling, Esq.	Dr. A. Henry.
C. T. Carter, Esq.	C. F. J. Lord, Esq.
T. Charles, Esq.	Dr. O'Connor.
W. Collins, Esq.	Dr. Semple.
Dr. Cormack.	Dr. Ogier Ward.
Dr. R. P. Cotton.	

Dr. ALEXANDER HENRY was appointed secretary to the committee.

After considerable discussion, the following resolutions were unanimously adopted.

1. That this Committee think that it is the duty of the Metropolitan Counties Branch of the Provincial Medical and Surgical Association to support a Medical Reform Bill, so far as it shall give effect to the great principles of uniformity of education, reciprocity of privilege, and the registration of legally qualified practitioners; but that they forbear to express an opinion on the details until an amended bill is before the Committee.

2. That Mr. Hastings, the secretary of the Medical Reform Committee of the Parent Association, be requested to furnish this Committee with a copy of the amended bill, as soon as it is possible for him to do so.

3. That the Committee, in accordance with their powers to increase their numbers to twenty-five, do request Dr. F. W. Mackenzie & Dr. R. H. Powell to become members of the Committee.

4. That Dr. Semple be requested to call the next meeting of the Committee when it may seem most expedient.

Names of the absent members of committee.

Mr. Ansell.	Mr. Shillito.
Dr. Risdon Bennett.	Dr. Sibson.
Mr. Richardson.	

NORTH WALES BRANCH.

THE Annual Meeting of the North Wales Branch will be held at Holywell, on Tuesday, the 21st day of June, 1853, at half-past eleven in the forenoon.

ED. WILLIAMS, *Hon. Secretary.*

EDITOR'S LETTER BOX.

THE OUT-PATIENT NUISANCE.

LETTER FROM BENJAMIN TRAVERS, ESQ., JUN., TO THE EDITOR.

SIR,—I always read your remarks on hospital abuses with interest, as it is a subject to which my attention has long been directed. While I concur generally in your views, I would like to see your advocacy of the repression of that vile hospital nuisance—OUT-PATIENTS—go the length of a proposition for its TOTAL ABOLITION in all the London hospitals. The dispensaries are more than enough for the gratuitous work which can be legitimately imposed upon the profession. More ample in-door accommodation could be provided, if a stop were put to the present waste of means in the out-patient department. The only persons who ought to be regarded as having any claim as out-patients at our hospitals, are those suffering from the effects of poison, or from surgical casualties, such as wounds, retention of urine, and hernia.

The question which I have now submitted for your consideration is one which I raised some years ago, when I resided in the Borough. I sent a memorandum on the subject to the present treasurer of St. Thomas's Hospital; but I suspect that it has long ago been laid in forgetfulness, the usual tomb of kind suggestions. I have not forgotten it, however; and I believe I am correct in stating generally, that the feeling which I have expressed regarding the out-patient system, is as general within as without the walls of the great metropolitan hospitals. The system is a nuisance which ought to be abolished.

I am, etc.

8, Dover Street, Piccadilly, June 1st, 1853.

ADVICE GRATIS: PHYSICIANS AND GENERAL PRACTITIONERS.

SIR,—I have been a not inattentive reader of your various leading articles upon the subject of Hospital Abuses; and being myself attached to a large institution, I daily see how applicable the remarks of yourself and correspondents are in reference to an evil, which threatens ere long to injure our noble profession, by rendering its claims to *individual* respect nugatory and inoperative, though the readiness with which it supplies all and sundry with gratuitous aid.

But while you blame the physician for giving his time and talents to these so-called charities, it were well to consider his present position, in reference to what in modern times is called "the claims of the general practitioner". I presume your correspondent "OBSERVATOR" is one of those "physicians to nine-tenths of the community", who now find fault with an evil which they have brought upon themselves. I am old enough to remember the profession thirty years ago, when "advice gratis" was a thing almost unknown, an anomaly and excrescence which was then slowly creeping in, but which has of late largely increased in growth *pari passu* with the educational requirements of the Apothecaries Hall, whose licentiates now-a-days being so highly educated, repudiate the very idea of superiority in the physician. In the days of old, the apothecary, when in doubt or difficulty, invariably called in a physician; and, for the honour of the grade to which I belong, their services were at the call of the very poorest of the community. Now, alas! consultations are rare, and when needed they are grudgingly accorded by the very men whose duty it is to suggest them!

Thus our rooms are crowded with a class of people far from poor, whose almost invariable cry is, when remonstrated with, "Sir, I have been three months under Mr. Dosewell, who has done me no good; I have a large bill to pay, I hear you are good enough to give your advice gratis, and I have come to you." Now, if Dosewell had two months before asked us to visit poor Quinsey, and told us that he was unable to pay more than one fee for two or three consultations, we should have been called in; but our friend is chary of his reputation, and wishes to take all the credit and the cash himself. And thus, were the physician not to adopt the "advice gratis" system as a means of introduction to practice, he would starve; repudiated by the general practitioner, he throws himself upon the public, and by patching up the constitutions of the poor, he hopes eventually to make a name with the rich; for he knows that if he depends upon his brethren in the profession to consult him voluntarily, he must either be independent of it altogether, or starve in his endeavours to succeed in it.

Thus driven by the general practitioner from his legitimate sphere of consultation, how is he to gain reputation? Anxious to keep *au courant*, he daily peruses the Medical Journals, and anxiously seeks for an appointment to a public charity; and failing in this, or even if he succeeds, he opens his rooms for seeing a better class of patient. The cases which thus present themselves are for the most part chronic, and which have been for some time past under the care of the general practitioner; these he succeeds in curing, but no sooner is his name and fame blazoned abroad, than he is subjected to the rancorous jealousy of his brethren, and his chance of consultation practice is farther off than before. If I take an obscure case, my will, or the lease of my house, to a solicitor, he invariably advises me to take counsel's opinion; but I may daily see, chronic and obscure cases of disease requiring correct diagnosis, under the care of one general practitioner, wherein, if ever a physician's advice is sought, it is on the sly, at the earnest solicitations of friends, and contrary to the advice of the general practitioner. I for one will never refuse to give my time to the consideration of such cases, until my neighbour feels it his duty to consult the higher grades of his profession; for then, and not till then, will the present anomalous system of indiscriminate hospital relief, and "advice gratis" cease and determine.

It is useless to complain, until we can act together as an undivided body—class interests warring with each other are the cause of all the many evils which afflict the profession. I maintain that when the general practitioner *again* feels it his duty to consult the physician in cases where his advice is needed, there will be no occasion for the physician to resort to the crowded consulting room of the hospital or dispensary for experience and practice; no occasion for him to see a single "gratis" patient that does not come to him with a letter from his neighbour and friend, his fellow practitioner, and fellow labourer.

I could relate many instances which have come under my own observation, where the practitioner has voluntarily surrendered

his patient rather than meet a physician in consultation. As long as the present system continues, not one in ten of the physicians can possibly earn a livelihood; he must be independent of his profession, for his profession is seeking to be independent of him. As the late Earl Grey once said in parliament, we must support our own order; so my present remarks are not intended either to insult or annoy the general body of medical practitioners, but rather to show that evils have sprung up in the medical body politic, the seeds of which have been sown broad cast by themselves; and that as long as the general practitioners repudiate consultations, so long will specialities, hospital abuses, and advice gratis, continue.

I am, etc.,

A SENIOR PHYSICIAN.

May 21st, 1853.

[The subject of this letter will on a future occasion engage our attention.—EDITOR.]

CHLOROFORM IN LABOUR.

LETTER FROM CONWAY T. EDWARDS, Esq., TO THE EDITOR.

SIR,—I have used chloroform in labours for several years, and now rarely attend them without exhibiting it.

I pour a little on a handkerchief, and the patient inhales the vapour as a scent. The first attempts are usually failures; but soon, as a certain calmness steals over her, she becomes desirous of continuing the inhalation, feeling the perfume to be agreeable. At this point, the practitioner will show her the way to breathe it, so as to produce the effect he may require—a kind of dreaminess. In this condition, all seem to experience, what some few express, "patience to bear their sufferings". And in this state may Her Most Gracious Majesty have been placed by Dr. Snow, and that tranquillity induced in the pauses of uterine contraction, which finds expression in the words—"I feel I have patience to bear my pains".

One case has occurred in my practice in which insensibility was produced. The duration of anæsthesia was only whilst the head and body were passing the outlet. The return to consciousness was attended by a disbelief that the labour (so far as the fœtus was concerned) had terminated. This was in 1850.

The convalescence, as in all other instances where chloroform is used, was unusually rapid.

It is, therefore, satisfactory to feel assured, that whilst a partial anæsthesia is attended with no danger, or any unpleasant symptom, it mitigates suffering; does not interfere with that regular, and equal, and powerful uterine contraction, so necessary for proper fetal and placental expulsion; greatly modifies nervous irritability; and materially accelerates convalescence.

Another point of some importance to the mother, and one which I do not remember to have seen noticed by any practitioner, is this: that the infants of mothers confined under chloroform are particularly quiet and gentle in their tempers. Should any practitioner have made a similar observation, perhaps, with Captain Cuttle, he will "make a note of it".

Such being some of my experiences in chloroform, it was with no ordinary feelings of gratification that I perused your able article on the accouchement of Her Majesty, and entirely concur with you in your opinion "that the cautious inhalation of the vapour of chloroform during labour is entirely free from danger, and calculated to afford *merciful relief* from pain, in one of the most agonizing trials of humanity".

I am, etc.,

CONWAY T. EDWARDS.

Batheaston, May 28th, 1853.

MEDICAL REGISTRATION UNDER THE PROPOSED ACT.

LETTER TO THE EDITOR.

SIR,—Would you be good enough to tell me, Whether, under the reformed system of medical qualifications proposed by the ASSOCIATION, I can register as a general practitioner, without undergoing a further medical examination?

I am a surgeon (London), of five years standing, and hold a diploma in midwifery from the Dispensary Lying-in Hospital. I am now an assistant; and a very startling hypothesis founded upon this fact having been hinted to me is the reason why I thus trouble you.

I am, etc.,

E. W. S.

Ilford, May 24th, 1853.

[You will be entitled to register without undergoing any additional examination.—EDITOR.]

NEWS AND TOPICS OF THE DAY.

MESMERIC IMPOSTURE AT ASHTON-UNDER-LYNE.

[The following paper has been forwarded to us by Robert Wood, Esq., of Ashton-under-Lyne. We congratulate Mr. Wood upon the moderation and success with which he has vindicated himself from the insolence and gross calumnies of Mr. Light. The attempt at Mesmeric imposture was clumsy and contemptible.—EDITOR.]

The Rev. John Light, *senior* curate of the parish church, Ashton-under-Lyne, has been unusually busy of late in what he calls a duty, but which I consider, at least, a gross misstatement (and in my mind a wilful one), viz., that in "the repeated applications of the ammonia" to test the reality of Mesmerism, at the Town Hall, on the 26th ult., my "conduct was cruel, and throughout unbecoming as a medical practitioner", etc.

The rev. senior's *duty* (alas! for his parochial duties,) has not been without effect; he has rendered himself liable to serious consequences, which, as I feel no vindictiveness, I will not specify.

In order that the public may the more fully appreciate the case, I think it desirable to state that, at a meeting of the Ashton Medical Association, a letter to Captain Hudson was signed by the members present, requesting him to allow them to test his competency to produce the so-called Mesmerism by a meeting, either public or private, as they had no wish to prejudice him in any way with the public.

A messenger was sent with this, and desired to bring an answer. No answer, however, was returned. The messenger made two subsequent applications with a like result; and as Captain Hudson had spoken of the letter publicly at the Town Hall, on the evening of the 22nd ult., two of us (members) called upon him. We stated that we could not credit any part of his practice, and after a time it was arranged that we should meet him at his room, in the Town Hall, at three o'clock on Tuesday, the 26th ult.; and as we could place no reliance upon the honesty of the people in his pay, it was reluctantly conceded that we should find him subjects to operate upon. He announced from the platform on the 23rd, when the meeting would take place, and many attended.

On entering the room, I found Mr. Light (who had no right there except as a spectator) in very loud talk and great gesticulation, exclaiming "Great is Diana of the Ephesians, the *craft* is in danger". I could only understand from this, that he intended to impute unfairness, as he styled the medical profession a *craft*. I would respectfully refer the clerical gentleman to a text, "1 Corinthians, chap. xiii, verses 4 to 7", and leave the public to decide whether he has practised its precepts.

I saw that the intention of Mr. Light was to make himself obnoxious, and this being the opinion of others, it was thought desirable to have a chairman; and we were fortunate in having present Wm. Bass, Esq., of the Lodge, Dukinfield.

On commencing proceedings, the rev. gentleman insisted upon Captain Hudson operating upon his own people, contrary to our previous agreement. This was of course objected to; for on this condition, I am sure none of us (the Medical Association) would have had anything to do with the business. Great clamour was made by Mr. Light, on the ground that Captain Hudson could better operate upon others after he had obtained a magnetic current of sufficient power in his own people. We then conceded everything, with an understanding that Captain H. would undertake to place one of his own people in a state of total unconsciousness of all external sensations; that this state should continue till he chose to "de-Mesmerize" him, and that he should be put to any test we liked as to its reality, which I promised should be void of everything that would create pain, or have the slightest appearance of cruelty. With this understanding, the captain proceeded by placing one of our people upon a form between his own subjects. His servants were soon, and to our minds collusively, "Mesmerized": not so, however, with ours, notwithstanding the great supply of magnetism; and of course the experiment was a total failure.

At this stage of the proceedings, the captain whistled continuously the Old Hundredth Psalm, to the very evident edification of the senior curate; and on touching the bump of veneration, two of his subjects placed their hands in an attitude of devotion, and slowly sank on their knees: a continuation of this mockery was stopped by the chairman, at the request of a part of the audience that we should proceed to business.

The captain then brought out a bottle containing, as he stated, the strongest "Harmonier", (ammonia) with which he proposed to test his man; he had so far had his uninterrupted sway, but it was for others to apply the test, and this was insisted upon by the chairman. I was prepared with a bottle of pure liquor of ammonia, of the strength of hartshorn, totally different in colour and every other feature from that produced by the captain, and what I daily use in practice. The man was then turned about by the Mesmerizer, and to our amusement, instead of being rigid, he moved his legs, and placed himself with his head very much back. The bottle was then with much difficulty (owing to his posture) got near to the man's nostrils; but knowing all that was going on, he resolutely held his breath. Captain Hudson, supported by Mr. Light, soon interfered, by seizing my arm and drawing the bottle away, in time for him to breathe, accompanying this with some very disgraceful language: he thus allowed of no application whatever, for it could take no effect unless the man inspired. Hence Mr. Light's misstatement in speaking of "repeated applications". Where is the cruelty if the ammonia had been applied?

At this point, the senior curate sprang forward, and heaped abuse upon me, stating, amongst other things, that my conduct was "diabolical". I noticed him no further, than by observing, that, as I had before stated, I would be no party to cruelty.

Captain Hudson then brought forward a young gentleman, whose character, he said, was well known to some of us; but it was found convenient for the captain's friend (the reverend gentleman before mentioned), through a third party, to excuse his inhaling the hartshorn, on the plea of ill-health. This fact, it seems, had escaped their notice, till it was discovered that an exposure must be the inevitable result; and thus no test was applied in his case.

Mr. Light himself then came forward, loudly demanding whether he was a man of character? It was admitted that he had established his reputation by frequent communion with his friend the captain; and he was operated upon to our infinite amusement.

"Doubtless, the pleasure is as great,
Of being cheated, as to cheat;
As lookers-on feel most delight,
That least perceive the juggler's sleight;
And still the less they understand,
The more admire his sleight of hand."

After all this nonsense, Captain Hudson was asked to try a few in the room, whose *imaginings* would not carry them beyond the bounds of propriety. Ten were thus tried, and, I need not say, all failed, as was the case with ten at his private meeting the night before, to the supreme disgust of all. The captain declined to try again.

He was then invited to give us a sample of clairvoyance, of which he has boasted so much in other places: this was declined, no doubt because he was thoroughly taken down in Rochdale. How does the senior curate reconcile Mesmerism and clairvoyance with the doctrines he professes to teach?

The chairman then took the sense of the meeting on two propositions:—

I. Whether Captain H. had succeeded with the people he himself brought forward? This, of course, included Mr. Light; it was negatived, although the captain's people voted.

II. Whether Captain H. had produced any effect upon those with whom he had had no previous dealings? This was also negatived.

Captain Hudson is said to have shewn a bloody pin to his audience on the evening of the 26th, and to have said, that after he had left the meeting with the medical men, it had been drawn from the thigh of one of his people, and to have insinuated that it was placed there by one of us. This is really too good a joke to be believed, except, indeed, by such as the senior curate, who, I understand, has lost no opportunity of making the most of it.

Had he thought during a very small portion of the valuable time it has taken to heap slander upon the medical profession, he would have seen facts sufficient to have shewn this to be a falsehood, and might not then himself have swallowed the pin.

"Slander, that worst of poisons, ever finds
An easy entrance to ignoble minds."—HARVEY.

"His lustful orgies he enlarged,
Even to the hilt of scandal."—MILTON.

"I do fawn on men, and hug them hard,
And after scandal them."—SHAKESPEARE.

The same evening I wrote to Mr. Light, as follows:—

"Warrington Street, April 26th, 1853.

"REV. SIR,—At the Town-Hall, this afternoon, you were pleased to say, in reference to the part I took in Captain Hudson's proceedings, that my conduct was diabolical. I ask for an explanation. I am, etc.,

"(Signed) R. WOOD.

"To the REV. J. LIGHT."

I received his answer immediately.

"The Rectory, Ashton-under-Lyne, April 27th, 1853.

"SIR,—I don't remember having said any such thing as you charge me with, and feel certain I did not.

"Had I said this,—that the repeated application of the ammonia was cruel, and your conduct throughout unbecoming a medical practitioner, and the investigation of a grave scientific subject, I should have said what I shall feel it a duty to confirm anywhere, or for the satisfaction of any one.

"I am, etc., JOHN LIGHT."

Feeling that the reverend gentleman had quibbled about the charge I made against him, had added another insult in his letter, and stated a direct falsehood about "repeated applications of ammonia", as I have before shewn, I forwarded his note to Mr. Bass, to Mr. Alfred Aspland, and to the Rev. Mr. Quirk. The following were the results:—

"The Lodge, April 28th, 1853.

"DEAR SIR,—In answer to your inquiry, whether I saw anything in your conduct on Tuesday last, to justify the expression contained in the accompanying note of Mr. Light, I readily give you the assurance, that from the most impartial and attentive observation I was able to give to the proceedings of that day, I could discover neither cruelty or anything whatever unbecoming the character of a medical practitioner; but on the contrary, I am of opinion that you and your professional brethren shewed great forbearance under the treatment you were subjected to in your endeavours to investigate a grave scientific subject.

"I am, etc., WM. BASS."

"Dukinfield, April 28th, 1853.

"MY DEAR SIR,—At your request, I send you the following statement. I was present at the Town-Hall, on Tuesday last, and saw you apply the ammonia to the nostrils of the person who was stated to be rendered Mesmerically unconscious; you did this with discretion and care, using the stimulant as medical men do with fainting persons. The man resolutely held his breath; but when it became evident that he must inspire, the Mesmerizer hastily drew him away, using some abusive language.

"The Rev. Mr. Light twice declared that your proceeding was diabolical. This was heard and commented upon by several gentlemen near me. Amongst them, I may mention Mr. Boyd, of the 4th regiment; Mr. Hope Vere, of Manchester; and two surgeons living in the district. At the close of the business, I remonstrated with Mr. Light for his violent language. He denied the use of the word *diabolical*, but used other terms, which not being publicly spoken, I need not further allude to.

"Regretting very much that you and the medical profession in the neighbourhood should have been subjected to obloquy and insult, for the exposure of a miserable imposture,

I am, etc.,

"ALFRED ASPLAND."

"R. WOOD, Esq."

"April 30th, 1853.

"MY DEAR SIR,—Most willingly do I accede to your request that I should give my opinion of your conduct at the meeting on Tuesday last. And my opinion is this, that your object was to test in a fair manner, the truth of the propositions then stated, and the honesty and sincerity of the persons operated upon. I believe that you were open to conviction had these persons stood the tests which you, in concert with other medical men, thought proper to apply, and if additional proofs had been exhibited. And I am quite sure, that not under any circumstances would you be guilty of an act of cruelty, or put any person to the slightest pain, except under the expectation of benefit to result from it. And I am further of opinion that your conduct was quite becoming a professional man on such an occasion.

I am, etc.,

"ROBERT WOOD, Esq."

"C. T. QUIRK."

I may say these are not all I have had, denying the base and malicious aspersions. I did not, however, then send any of them to Mr. Light, from the hope, that after he had had time to deliberate, a further appeal might have some effect; and I wrote as follows:—

"Warrington Street, April 29th, 1853.

"REV. SIR,—Your note of the 27th inst. does not satisfy me. I think I have a right to a definite explanation of what I charged you with. I am, etc.,

"R. WOOD."

"To the REV. J. LIGHT."

I got his answer immediately.

"The Rectory, Ashton-under-Lyne, April 29th, 1853.

"SIR,—If it takes you two days to quite assure yourself that my reply to your first note—which any reasonable man would deem explicit enough—is unsatisfactory, then there is but one alternative. I must leave you in your present condition of mind—dissatisfied.

I am, etc.,

"JOHN LIGHT."

"R. WOOD, Esq."

To this, I responded.

"Warrington Street, April 29th, 1853.

"REV. SIR,—I am in receipt of your note of this morning. I hoped that the two past days had afforded you time for deliberation, and that you would have taken a different course; and I have hitherto forbore sending you the accompanying copies of letters from Wm. Bass, Esq., chairman of Tuesday's meeting, and from Mr. Alfred Aspland; but now I have to ask you to retract all offensive expressions you have used towards me, both personally at the Town Hall, and in your letter of the 27th; and as you have put in practice your declaration and threat as contained in that letter, the retraction must, of course, be expressed to all parties you may remember thus to have spoken to.

"Besides this, I have to request a suitable apology for all your abusive and injurious language which may otherwise apply to me in my private life, as well as in my professional calling.

"If you refuse to accede to the conditions I have above expressed, I shall feel called upon to take such a course as my friends may advise.

"I shall be glad to hear your determination by Monday next.

"I am, etc., R. WOOD."

"To the REV. J. LIGHT."

"P.S.—Since the above was written, I have received communications from the Rev. Mr. Quirk, expressive of his opinion of the proceedings of Tuesday. I send you a copy also of this letter.

"R. W."

And I received his ultimatum.

"The Rectory, Ashton-under-Lyne, April 30th, 1853.

"SIR,—As I have no time, and less disposition, for any unnecessary correspondence, I beg, once for all, to assure you that I shall not apologize for what I have not said, or retract what I sincerely believe, or allow the opinions of your friends to interfere with mine, in any way or degree.

"I write thus immediately, that there may be no delay in your applying for any advice which you may deem expedient, or your friends may be able to give you.

I am, etc.,

"JOHN LIGHT."

"R. WOOD, Esq."

The last letter is an excellent sample of the man, and carries with it a brilliant dash. I own myself at a loss in any problem that will resolve itself like the first part of the reverend gentleman's letter into less than nothing; and the second is but a common example of his consummate assurance.

As regards his allusion to my friends, I will simply observe, that I had not the pleasure of Mr. Bass's acquaintance, until I met him at the Town Hall; the reverend gentleman, however, came direct to the meeting from his (Mr. Bass's) hospitable board.

Other parties I have alluded to, and whose advice I had sought, have been hitherto considered fast friends of Mr. Light; but I much regret, after communication with several of them, to find that it is quite common for him to contradict and affront them. I keep to the opinion I first formed of the man, and have still in my own mind to compare so reverend a divine with the renowned Bombastes Furioso.

ROBERT WOOD.

Warrington Street, Ashton-under-Lyne, May 7th, 1853.

Some delay has occurred in printing the report of the meeting, in consequence of Mr. Light having declared that he would take care it was published; probably, he found a verbal report to the public would place him under less restraint.

R. W.

MEDICAL BENEVOLENT COLLEGE. At a meeting of the Council, held in the Hanover Square Rooms, on the 31st ult., the President, the Earl Manvers, in the chair, a Committee was appointed to make the necessary arrangements for receiving His Royal Highness Prince Albert, on the occasion of His Royal Highness laying the foundation-stone of this National Institution, on the 4th July. Thanks were voted to the Bishop of Oxford, for his Lordship's effective Sermon on the 8th ult., in behalf of the College, and his Lordship was elected a Vice-President; as was also Sir James Clark, Bart., M.D.

ANNUAL DINNER OF THE MEDICAL OFFICERS OF THE ARMY. On Saturday, May 21st, the medical officers of the Queen's army held their annual dinner at the Thatched House Tavern, St. James's Street: G. J. Guthrie, Esq., F.R.S., in the chair. This dinner is held yearly upon the day of the meeting of the Friendly and Benevolent Societies of the medical officers of the army; and the proceedings of the evening had special reference to these admirable and flourishing institutions. The Friendly Society affords annuities to the widows and orphans of its members; the Benevolent Society is purely charitable. Both owe their origin, and much of their success, to the late Director-General of the Army, Sir James M'Grigor. The capital fund of the Friendly Society now reaches £77,000, and that of the Benevolent Society £15,000. Among the toasts of the evening were, Dr. Paris and the College of Physicians; Mr. Caesar Hawkins and the College of Surgeons; the Apothecaries' Society and Mr. Parrott of Clapham (one of the Wardens, the Master of the Company being unavoidably absent); Dr. Andrew Smith, Director-General of the Army Medical Department; Sir James M'Grigor, late Director-General; Sir De Lacy Evans, and the friends of the profession in the House of Commons; Dr. Semple, Dr. Tyler Smith, and Dr. Cormack, in connexion with the medical press of the metropolis. In returning thanks for the toast, Dr. T. Smith remarked, that his connexion with journalism belonged more to the past than the present: and Dr. Semple stated, that he was only an interim editor—that he had no wish to be anything else, for he thought there were other professional occupations less responsible and more respectable. The proceedings were enlivened by the band of the Coldstream Guards; and altogether the evening passed off merrily and happily.

NEW DISPENSARY, CLAPHAM. Last Friday week, Captain Bowyer, the Lord of the Manor, laid the foundation-stone of this dispensary, on a site which he had given for that purpose. The ceremony was performed under a splendid awning, and was witnessed by 400 spectators, including the Bishop of Winchester; the Rev. H. Wentworth, the Rector; Lady Napier; Lady Pollock; Drs. Sylvester and Topson; and Messrs. Mainpress and T. H. Hewit. The Bishop of Winchester having pronounced a benediction, A. Bowyer, Esq., presided at a *déjeuner* given at the rectory, on which occasion he stated that, since the dispensary originated, in 1849, the medical officers had gratuitously rendered their services, and that during that period 3,000 sick poor had been visited and prescribed for by those gentlemen. Was this dispensary wanted?

PHARMACEUTICAL SOCIETY: DEPUTATION TO LORD PALMERSTON. On Friday, May 27th, a deputation of members of the Pharmaceutical Society waited on the Home Secretary (Lord Palmerston), to call his lordship's attention to the illegality and injustice of the proposed New Bye-laws of the Society, with a view to induce his lordship to withhold from them his confirmation, as he is empowered to do by the Act of 1852. His lordship listened with the utmost courtesy to the representations of the deputation, requested a copy of any documents bearing on the subject, and promised that the whole subject should receive his best consideration.

EPIDEMIOLOGICAL SOCIETY. At the ordinary meeting of the society, to be held June 6th, at half-past eight P.M., a paper, by Dr. Milroy, will be read, entitled "Sketch of the most striking Results of Quarantine in British Ports since the beginning of the present Century".

TREATMENT OF CHARLES II., DURING HIS LAST SICKNESS. All the medical men of note were summoned, and one of the prescriptions was signed by fourteen doctors. He was bled largely, a hot iron was applied to the head, and a volatile salt, extracted from human skulls, was forced into his mouth. He survived this treatment four days.—*Macaulay*.

ROYAL COLLEGE OF SURGEONS:—PASS LIST. MEMBERS admitted at the meeting of the Court of Examiners on the 20th instant:—George Evans, Harewood Square; Charles Lambert

Evershed, Billingham, Sussex; William Hamilton, Tullick, co. Tyrone; Andrew Henderson, Kirkaldy, Fifeshire; William Hopkins, Leamington, Warwickshire; Augustus Johnston, Dublin; William Henry Moor, Durham; John Pichall, Hon. East India Company's Service, Bengal; John Rains, Bonsal, Derbyshire; Edward Malcolm Sinclair, Manchester; Robert James Wilson, Westminster.

APOTHECARIES' HALL:—PASS LIST. Thursday, May 19th, 1853:—Edward Atkinson, Little Woodhouse, Leeds; Richard Wafford Eve; Henry Hancock, Bilston, Staffordshire; Robert Walker Jenkins, Charing, Kent; Charles Scholefield Richard-son; John Tibbits, Warwick; Peter Wright, Wigan.

APPOINTMENTS.

[*An asterisk is prefixed to the names of Members of the Association.]

BISHOP, John, Esq., F.R.S., appointed one of the Lettsomian Lecturers to the Medical Society of London, for the session 1853-4.

GOODEVE, C., M.D., Professor of Materia Medica in the Bengal Medical College, to be *ex officio* Second Physician of the College Hospital, and Professor of Clinical Medicine.

MOUAT, F. J., M.D., Professor of Medicine in the Bengal Medical College, to be *ex officio* First Physician of the College Hospital.

O'SHAUGHNESSY, R., Esq., F.R.C.S.Eng., Professor of Surgery in the Bengal Medical College, to be *ex officio* First Surgeon of the College Hospital.

STEWART, D., M.D., Professor of Midwifery in the Bengal Medical College, to be *ex officio* Obstetric Physician of the College Hospital.

•**THOMPSON, Theophilus, M.D., F.R.S.,** appointed one of the Lettsomian Lecturers to the Medical Society of London, for the session 1853-4.

WEBB, Allan, Esq., Professor of Descriptive and Surgical Anatomy in the Bengal Medical College, to be *ex officio* Second Surgeon of the College Hospital, and Professor of Clinical Surgery.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were Members of the Association.]

COLVILLE, Eliezer, Esq., Surgeon, at Ayton, Berwickshire, aged 66, on May 21.

FOX, Samuel, Esq., Surgeon, at Shoreditch, aged 77, on May 23.

•**MINES, William, Esq.,** Surgeon, at Diss, Norfolk, aged 77, on May 14. Mr. Mines had been in practice for forty-nine years, with much success.

SIDLEY, —, Esq., Surgeon, R.N., at Southampton, suddenly, on May 15. He is believed to have died from an overdose of prussic acid.

STOCKER, Henry Medland, Esq., Surgeon, at St. Austell, Cornwall, aged 21, on May 12.

TRAYERS, Joseph, Esq., F.R.C.S., at Mossell Bay, South Africa, in March last.

WATKINS, Dr., Civil Surgeon, and formerly Garrison Surgeon at the Bombay Presidency, at Breach Candy, of dysentery, on April 2. He was in extensive private practice. He served during the whole campaign in Scinde and Afghanistan, and was present at the storm and capture of Ghuznee.

BOOKS RECEIVED.

[*An asterisk is prefixed to the names of Members of the Association.]

+**LITTLE, W. J., M.D.** THE NATURE AND TREATMENT OF DEFORMITIES OF THE HUMAN FRAME. pp. 412. London: 1853.

STEVENS, William, M.D., D.C.L. Oxon. NATURE AND TREATMENT OF ASIATIC CHOLERA. 8vo. pp. 449. London: 1853.

PORTRAIT OF MR. LUKE. We have received from Mr. T. M. Stone, of the Royal College of Surgeons, an admirable portrait of Mr. Luke, of the London Hospital. It forms one of Mr. Stone's beautiful series.

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London; or to the office of the Journal. Letters requiring immediate attention and revised proofs ought invariably to be sent to Putney.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XXIII.

LONDON: FRIDAY EVENING, JUNE 10, 1853.

NEW SERIES.

THE ART OF PRESCRIBING, IN ITS RELATION TO GENERAL PRACTICE.

WHEN the philosopher said, that "God has not been so sparing to men to make them barely two-legged creatures, and left it to Aristotle to make them rational", he meant that mankind possess a native faculty to use their reason without being instructed in methods of syllogizing, and that the shepherd has no need of the courtly arts of ratiocination to teach him that "the property of rain is to wet, and fire to burn; and that he that wants money, means, and content, is without three good friends." Now, if Touchstone had lived in this golden age of quackery, we think he must have included the clown's way of dealing with sham physic among his "Instances" of "Natural Philosophy".

We are acquainted with nothing in the whole history of our science more striking than this fact, which is known to every parish doctor in the realm,—that not only are all forms of spurious medicine dependent on the educated and wealthy for their support, but that if any board of guardians in England were to attempt to condemn their poor to the supervision of a professed disciple of Meamer, Hahnemann, or any other heretic, the serfs of the soil would rise to a man, and resist the abominable fraud. With this preamble, we proceed to the main points of our argument.

It has been frequently said, that our forefathers brought upon us the homœopathic incubus, by their system of drenching; in fact, that when people had been surfeited with physic, they naturally ran to the opposite extreme, and eagerly embraced a creed which promised their gustatory nerves an exemption from "nasty stuff". If this assertion, then, be true (and there is every reason to believe that it is so), another and a far more weighty effect has followed in the wake of this popular movement; viz., the determination on the part of the profession at large to abandon the universal practice of drugging their patients, for one less disgusting to the sick, and equally advantageous to the doctor. The plan which is now coming generally into use, of charging for visits and attendance, is in itself every way desirable; but it cannot be forgotten that the new doctrine is suggestive of new methods of prescribing; and it may be worth while to consider whether we are not losing substantial good, in our endeavours to satisfy the whims of patients, by attempting to reduce our prescriptions to the attenuated formulæ of the medicine chest.

We now propose to examine into this matter a little more narrowly; and, for convenience sake, we shall divide the subject into two parts.

First, let us inquire how far we may with safety depart from old-established forms of prescribing; and, second, whether the progress of such a reform is affecting, or is likely to affect, those who dispense the physic that is swallowed. Let it be once for all understood that our observations do not in any way apply to the operations of the retail apothecary or druggist, since we are now concerned

only with the acts and prospects of that large body of men, who prescribe and send out their own medicines from their private houses—namely, the general practitioners.

The art of prescribing is to the doctor what the art of colouring is to the painter. Both have the power of producing the same results by different processes. The painter, by the aid of "hand and eye", will compound on his palette two or more tints, which are identical in appearance and in their effects on the canvas, from a variety of colours; so the doctor, from the stores of his *materia medica*, will prescribe remedies derived from many sources, all of which shall have the same property, namely, that of removing some given symptom. In both cases, the real skill consists in judiciously applying the material to the thing to be done. Now we are very much inclined to carry our analogy further, and to suggest that what has been found to be true, and acknowledged universally, in the art of painting, may likewise be believed in that of medicine. The methods of mixing and laying on colours are settled by common consent among painters, and any deviation from academical rules is regarded by them as a piece of quackery; indeed, they have a precedent for the authoritative tone they adopt in the success of their time-honoured processes, as they appear in the works of the old masters; and can we point to no such precedent in the history of our art? The convenient forms, the exact quantity to be swallowed, the division of doses into four, six, or eight parts corresponding with our arbitrary divisions of the twenty-four hours, are among the first examples of the usefulness of the old system which occur to us; but we would come to closer quarters with our subject, and ask why it is that hospital authorities, which have the power to dictate their own laws to those who seek their aid, prefer holding fast the elder traditions, to adopting any scheme of pharmacy which seems to promise less labour, and at least equal efficacy? We recommend to our readers the *Pharmacopœia* of the Royal Hospital of Saint Bartholomew, as an illustration in point. That institution has for many years profited by the services of men not only among the ablest in the profession, but the least likely to be led away by their prejudices in favour of the omnipotence of physic: and yet the formulæ in use at that charity are both found to be the most advantageous to the inmates, and are copied and carried away into private practice by the students who are educated within its walls.

Now let us ask, Is there no other power at work than the will of the prescribers in this matter? We cannot but confess that the strong common sense, and native wit of the poor man, with which we set out, are the most active antagonists to all sweeping innovations; and we affirm that nowhere is this force from without made more apparent than in our dealings with the ordinary parish pauper. Your acknowledged pauper is a person who, having his mind encumbered by no metaphysical abstractions, has leisure and opportunity to concentrate his attention on things as they are: and, if you offend him, he at once gives you to under-

stand, either by direct word of mouth, or by a significant absence from your consultation room, that he thoroughly comprehends the nature of your reciprocal relations; and that, among other duties which he feels you owe to him and his, is that of supplying him with his remedies in a lawful and pharmaceutical manner. For example, let any union surgeon who affects to despise the mysterious *omne ignotum pro mirifico*, which his clients have been accustomed to believe in, venture to lay bare the naked truths of Epsom salts and magnesia, or systematically to instruct his patients to make their own infusions, (we speak now from actual observation of the results which have followed such practices,) and one of two things will happen; either his patients will scorn him as a niggard, or avoid him as a pretender.

The second division of our subject, to which we now address ourselves, will, we think, be found by no means so easy to dispose of as at first sight might appear.

The health of the million is certainly entrusted to the care of the general practitioner: it is therefore equally of importance to the public and the profession to watch narrowly the tendencies of the popular mind with regard to medicine, and to ascertain, if possible, from past experience, what effects any given condition of an existing state is likely to produce in the future. We are well aware that persons are to be found who believe that the laws of social government are just what men choose to make them, and that there are no boundaries to the decrees of human authority in the arena of politics. To such a doctrine we cannot subscribe, since daily observation of the *mores hominum multorum et urbes* convinces us that many results cannot be carried into effect, through an unalterable incompatibility in the elements which compose society. Let us see, then, whether some such restraint as we have mentioned is not at this moment tending to prevent the onward march of certain new methods, which have been introduced among general practitioners.

There has been, of late years, a strong bias, both in and out of the profession, in favour of separating the duties of the prescriber from those of the dispenser: many have adopted the plan; and there appears *primâ facie* no valid reason why it should not be generally carried into execution—at least, in cities and towns where druggists abound. In villages and country places the thing would be impracticable; and if it ever came into common use, the village doctor must either undertake to maintain at his own charge a druggist near his residence: or, what is more probable, consent to be divided from his brethren and to rank a little below them. We do not, however, anticipate any such vital change in our constitution; for we believe that the genius of the English people is wholly opposed to it. We have seen what happened in the olden time to the system of inductive philosophy which Bacon endeavoured to construct; how completely it fell to the ground without producing any practical results; and this failure has been shown to have been owing to a haughty disregard, so universally prevailing at the time, of those very mechanical arts at which we are, in our way, aiming a blow, when we seek to abandon the so-called servile offices which have hitherto been part and parcel of our art.

The assumptions and vapid hypotheses of the philosophers of the middle ages were mainly due to their contempt of manual operations. They missed, by their neglect of experiment, the only path by which they could obtain a

knowledge of the real properties of objects; and while they surveyed nature from their lofty position, and forged theories to account for the *causes* of things, totally disregarding the more immediate investigation of *effects*, they founded a school of false philosophy. The workers of those menial arts which were permitted to survive the dignified suppression of such resources, could not help adopting the speculative notions of their betters; and thus arose, from the shadows of observation without patient experiment, the creed of the alchemists.

We do not mean to say that the prospects of science will be absolutely forfeited by any radical reform in our professional manipulations; but we do mean to assert (and we appeal to history for the truth of what we state) that the tendency of all systems which aim at separating the doctrines of science from manual labour, is to give a wrong direction to the speculative mind; and, if generally followed out in our case, seriously to cripple the usefulness of medicine.

THE MEDICAL DEPARTMENT OF THE ROYAL NAVY, AND THE DISMISSAL OF DR. J. F. HENRY.

FIFTY years ago—in May 1804—Lord Nelson wrote as follows (from on board the *Victory*) to his friend Dr. Baird:—

“The health of this fleet cannot be exceeded; and I really believe that my shattered carcass is in the worst plight in the whole fleet. I have had a sort of rheumatic fever, they tell me; but I have felt the blood gushing up the left side of my head, and the moment it covers the brain, I am fast asleep: I am now better of that, and with violent pain in my side, and night-sweats, with heat in the evening, and quite flushed. The pain in my head, nor spasms, I have not had for some time. Mr. (now Sir George) Magrath, whom I admire for his great abilities every day I live, gives me excellent remedies; but we must lose such men from our service, if the army goes on encouraging medical men whilst we do nothing. I am sure much ought to be done for our naval surgeons, or how can we expect to keep valuable men? I look to you, not only to propose it, but to enforce it to Lord St. Vincent, who must be anxious to preserve such a valuable set of men to the navy.” [Clarke and M'Arthur, vol. ii, p. 367.]

When we see how distinctly, in the words which we have quoted, the hero of Trafalgar appreciated the importance of the medical department of the navy, and how essential he felt the maintenance of it to be for the health and efficiency of a fleet, it becomes utterly perplexing to find that the same indifference which existed when he wrote should still prevail at head-quarters, as to the obtaining and preserving valuable medical officers for the navy. The medical journals dutifully proclaim the scandalous position of affairs, and patriot statesmen demand from Parliament, upon the double plea of economy and humanity, the best medical talent for our gallant sailors which the resources of the nation can command; and yet naval assistant-surgeons are denied the consideration due to gentlemen, and the accommodation required for that conscientious study and registration of their experience, without which their duties can be but half performed. The tone in which admirals and other superior officers publicly speak of our profession is so disparaging as to scare the *élite* from a service which every patriot should wish to see them ambitious to enter, as a career pre-eminently honoured and esteemed.

We cannot help suspecting that the harsh sentence, of dismissal from the service, recorded at p. 515, as having been pronounced upon our colleague, Dr. J. F. Henry, Surgeon of H. M. Sloop *Star*, depended more upon an anti-medical animus than upon the justice of the case. The excitability of brain induced by service in unhealthy seas, and the general good conduct of Dr. Henry, were clearly proved, and ought surely to have been considered sufficient to suggest a milder sentence, even if not deemed enough to justify an absolute acquittal. We venture to make this remark, because the medical officers of the navy are, as a body, habitually treated with injustice; and also, because it is evident that, had the accused in the present instance been righteously sentenced—which, from the report, does not appear—the crime would have been most chargeable upon those who, having the power to attract the best men of our profession into the navy, use every means in their power to make it a mere refuge for young surgeons who can get no other employment.

THE PROSPECTS OF MEDICAL REFORM.

ON Friday last a deputation from the London Medical Reform Committee, headed by Dr. LANKESTER, waited upon Lord Palmerston. It received the following reply; which, we fear, means that Government has no intention of bringing any Medical Bill into parliament during the present session. The profession must, therefore, for the future show more determination and self-reliance.

"Lord PALMERSTON said he had understood from some quarters that unanimity existed in the profession, and from others that there were many objections to the present system. It was therefore evident that the question was one of a complicated nature; and the details were new to him. The question, however, should receive his attentive consideration, and he should be glad to be favoured with a copy of the bill to assist him, as the subject was doubtless one of an important and pressing nature."—*Daily News*.

At page 516 will be found Lord Palmerston's answers to certain pertinent questions addressed to him, in the House of Commons, by Lord Dudley Stuart. It appears that the College of Physicians is to have its Charter during this session. This measure, and the Pharmacy Act of last session, must, ere long, produce very great changes within our ranks.

ASSOCIATION INTELLIGENCE.

MEDICAL BENEVOLENT FUND.

At the meeting of the Committee of the Medical Benevolent Fund, held on May 31st, the Treasurer announced that since July 1st, 1852, the sum of £365:15:0 had been received in subscriptions; and £354:14:0 in donations: £584 had been spent in grants. The expenses had amounted to £53:14:3; and the balance due to the Treasurer was £51:10:3.

The Treasurer also announced that a poor gentleman, who had been elected an annuitant at the previous meeting, had been killed by a blow from a cab in the street.

The following cases were presented:—

I. An old medical man and his wife, so reduced in circumstances as to become inmates of an almshouse. They had been previously relieved, and they were now voted £2:10:0; and it was resolved that the name of the husband should be placed on the list of candidates for annuities.

II. The widow of a medical man who lived in the neighbourhood of London. He died in 1847, leaving seven children, the eldest of whom is subject to epileptic fits. The widow has endeavoured to maintain her family by teaching in private families. Recommended by Dr. Cormack, Dr. Ridge, and Mr. Shillito. Voted £20; £10 to be given at once, and £10 in November.

III. The widow of a medical man, aged 65; the husband formerly lived in Lincolnshire. The widow is now reduced to get her living by manual labour. Recommended by Dr. Gordon Latham and Mr. Phillips. Voted £5.

IV. The widow of a medical man, who keeps a school in order to provide for her five children, one of whom is now ill and at home from school ill. Voted £10.

V. The daughter of a physician, who endeavours to obtain a livelihood by literary pursuits, is in great difficulties and obliged to exist on the poorest food, which is scarcely sufficient to support life. Voted £10 a-year for three years.

NORTH WALES BRANCH:—NOTICE OF ANNUAL MEETING.

THE Annual Meeting of the North Wales Branch will be held at Holywell, on Tuesday, the 21st day of June, 1853, at half-past eleven in the forenoon.

ED. WILLIAMS, } *Hon. Secs.*
D. KENT JONES, }

SUFFOLK BRANCH:—NOTICE OF ANNUAL MEETING.

The Annual Meeting will be held at the Assembly Room, Ipswich, on Friday, the 24th of June.

The chair will be taken at 2 o'clock, by Robert Martin, Esq., of Holbrook.

JOHN KIRKMAN, M.D., *Hon. Secretary*.

SOUTH EASTERN BRANCH:—NOTICE OF ANNUAL MEETING.

The Anniversary Meeting of the South Eastern Branch will be held at the Sussex Hotel, Tunbridge Wells, on Wednesday, 20th June, at 12 o'clock precisely; Isaac Hargraves, Esq., President. Dinner will be provided at half-past 4 o'clock.

PETER MARTIN, *Hon. Secretary*.

METROPOLITAN COUNTIES BRANCH:—NOTICE OF ANNUAL MEETING.

At a Meeting of Council, held on the 7th of June, it was resolved that the Annual Meeting be held at Mr. Lovegrove's Brunswick Hotel, Blackwall, on Tuesday, July 19th, at 4 P.M., precisely. The Members will dine together at 6 o'clock. Members who intend to dine are requested to furnish their names to the Secretary as early as possible, and not later than July 10th.

Tickets for the dinner 10s. 6d. each, including ices and dessert.

JOHN FORBES, M.D., *President*,
T. OGIER WARD, M.D., *Hon. Sec.*

N.B.—Members of the Provincial Medical and Surgical Association have the right of becoming Members of this Branch by simply paying the Annual Subscription of 2s. 6d. to JOSEPH TOYNBEE, Esq., Treasurer, or T. OGIER WARD, M.D., Secretary.

GENTLEMEN WISHING TO JOIN THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION ARE REQUESTED TO APPLY TO THE GENERAL SECRETARY, TO THE BRANCH SECRETARIES, OR TO THE EDITOR OF THE JOURNAL.

The Annual Meeting will be held at Swansea on the 10th and 11th of August. Vide p. 470 of number for May 27.

ORIGINAL COMMUNICATIONS.

ON THE ADMINISTRATION OF CHLOROFORM DURING PARTURITION.

By JOHN SNOW, M.D.

It is unnecessary now to employ or allude to any of the abstract reasons which have been given for using or withholding chloroform during labour, since a sufficient number of observations have been made to enable the question to be decided by experience. I believe that no one disputes the power of chloroform to relieve the sufferings attendant on parturition; and, therefore, the only consistent objection that can be made to it is, that some danger or disadvantage may arise from its use. It is well known that, out of the vast numbers of patients to whom this agent has been administered for the performance of surgical operations, a few have unfortunately died whilst inhaling it, or a minute or two afterwards; but it is satisfactory to know that no accident of the kind has happened in the practice of midwifery. This should not be looked upon as a mere coincidence, for there are sufficient reasons for concluding that there is no danger from the exhibition of chloroform during labour by a medical man using ordinary care, even though he may have had no previous experience in its employment. In the first place, the effect which it is necessary to produce in parturition is so much slighter than is required for a surgical operation, that it is not necessary to approach even half way to a point that would be dangerous if it were exceeded; and, in the next place, the chloroform never requires to be given except whilst there is pain, the relief of which serves as a sign for its discontinuance; which sign is not present in exhibiting it preparatory to the commencement of a surgical operation.

There have, however, been some cases in which death has been attributed by certain authors to chloroform, which had been administered during labour. Dr. Ramsbotham relates one such case;* but I doubt whether he would have considered the result to be due to this medicine, if he had had an extensive experience of its use, either in obstetric or any other class of cases. The chloroform was given occasionally, and apparently very judiciously, during the last four or five hours of labour in this case. Dr. Ramsbotham relates that, at the conclusion of the labour, "the uterus contracted well, and the patient appeared comfortable. At the end of an hour and a half, however, distressing dyspnoea came on, attended with excessive lividity of the face, and all the signs of extensive engorgement of the lungs and heart. Her respiration became more natural under the means employed, and in three hours and a half she lay down to rest; but in half an hour she suddenly arose with a return of the most distressing dyspnoea: this was soon followed by convulsions, and almost immediate death." No inspection of the body took place.

A case somewhat similar to the above occurred in the practice of Dr. Murphy, who, however, does not attribute the fatal result to the action of chloroform.† In this case, the chloroform was exhibited very sparingly during the last two hours of labour, the patient not being rendered unconscious. She fell asleep after the expulsion of the placenta, but awoke in two hours with cough and difficulty of breathing. These symptoms increased in spite of treatment, and the patient died a little more than twenty-four hours afterwards. The lungs were found to be greatly congested, and the kidneys were in a pretty advanced stage of granular degeneration.

Fatal congestion of the lungs is one of the results of Bright's disease. I have seen it in the male subject. It is not improbable that, in the case related by Dr. Ramsbotham also, there was either permanent disease or temporary congestion of the kidneys, and that toxæmia existed

in both cases. The occurrence of convulsions a little before death in the latter case renders this the more likely.* At all events, the symptoms in the above cases do not coincide in the least with the known effects of chloroform, even when exhibited much more freely. It must be remembered also, that the unfavourable symptoms did not commence till an hour or two after the effects of the chloroform had subsided; and in this time the system gets more thoroughly rid of this medicine than of a dose of opium in two or three days.

As chloroform is not a preventive of all the "ills that flesh is heir to", it might be expected that puerperal mania should happen after some few of the many cases in which it is used, especially as it has been inhaled more generally by sensitive and susceptible patients than by others. Dr. Ramsbotham alludes, in a foot-note,† to an attack of puerperal mania "which had supervened on the exhibition of chloroform"; but he does not state at what period the mania commenced; whether, for instance, it was an hour or a month after the inhalation. Other cases, or possibly this same one, have been mentioned in the medical societies; but no particulars have been related. I have been told respecting one case of puerperal mania, that the patient had long been in the habit of inhaling chloroform very freely (taking it often when no one was present), to prevent attacks of epilepsy, to which she was subject.

It was said that, in some of the early cases in which chloroform was employed, the uterine contractions were so much enfeebled by it, that delivery had ultimately to be accomplished by the use of the forceps. It is not improbable that the over free use of this agent might lead to such a result; but I believe it would not arise from its judicious use. It has happened that, in all the cases of manual and instrumental delivery in which I have given chloroform, it was exhibited only in consequence of the operation; for the other cases in which I have administered it have all terminated without artificial assistance.

The propriety and advantages of administering chloroform in parturition being admitted, a frequent inquiry is, "In what cases ought it to be employed?" It will be readily conceded that, in cases where the pain is not greater than the patient is willing to bear cheerfully, there is no occasion to use chloroform; but when the patient is anxious to be spared the pain, I can see no valid objection to the use of this agent, even in the most favourable cases. The benefits arising from chloroform in severe cases of labour are experienced in a lesser degree in favourable cases; and the patient may be fairly allowed to have a voice in this, as in other matters of detail which do not involve the chief results of the case. The determination of the kind of labours in which chloroform should be used or withheld is really a matter of not much importance, because, as we pass from cases that are severe and protracted to those which are short and easy, the quantity of chloroform that is used, and the amount of diminution of the common sensibility, and of interference with the mental functions, become so trifling, that very little remains about which to hold a discussion. Indeed, from what I have observed of the continued use of this agent in medical cases, and its use by healthy persons for experiment, I believe that the quantity which is inhaled in a short and easy labour might be continued daily for an indefinite period, without appreciable effect on the health.

The above remarks apply also in some measure to the question as to the period of the labour when the exhibition of chloroform should commence; for, in proportion as the pains are feeble, it must be more sparingly administered. The most usual time when the accoucheur and I have determined that the inhalation should be commenced, has been when the os uteri was nearly dilated to its full extent, and the pains were taking on an expulsive character. In many of the cases which I have attended, it has, however, been commenced much earlier; for the suffering caused by

* Principles and Practice of Obstetric Medicine. Third edition, p. 169.
† See Lectures on Parturition, p. 474.

* See ASSOCIATION JOURNAL, January 31st, p. 66.
† Opus cit., p. 154.

the dilating pains in the first stage of labour is often very great, and the chloroform is consequently of the utmost service when employed at this time.

As regards the manner of giving chloroform, I shall first allude to cases not requiring manual or instrumental assistance. In such cases, when it has been determined to resort to inhalation, the moment to begin is at the commencement of a pain; and the chloroform should be intermitted when the uterine contraction subsides, or sooner, if the patient is relieved of her suffering. It is desirable to give the chloroform very gently at first, increasing the quantity a little with each pain, if the patient is not relieved. The practitioner easily finds, with a little attention, the quantity of vapour which it is desirable to give at any stage of the labour, and in each particular case; his object being to relieve the patient without diminishing the strength of the uterine contractions and the auxiliary action of the respiratory muscles, or with diminishing it as little as possible. At first, it is generally necessary to repeat the chloroform at the beginning of each "pain"; but, after a little time, it commonly happens that sufficient effect has been produced to get the patient over one or two uterine contractions without suffering, before it is resumed.

When the practice of inhalation in midwifery was first introduced by Dr. Simpson, he very naturally adopted the plan which is usually followed in surgical operations, making the patient unconscious at once, and keeping her so to the end of the labour. It was soon found, however, by other practitioners, that this is not necessary; and indeed it would not be safe in protracted cases. Drs. Murphy and Rigby were, I believe, amongst the first to state that relief from pain may often be afforded in obstetric cases, without removing the consciousness of the patient; and I soon observed the same circumstance.* Some persons indeed have alleged that the pain of labour can always be prevented, without making the patient unconscious of surrounding objects; whilst others have asserted that no relief can be afforded unless unconsciousness be induced. But both these opinions are directly opposed to experience. There are comparatively few cases in which the suffering can be prevented throughout the labour without interfering with consciousness, although there are very many cases in which it can be in this way prevented in the early part of the labour. This difference depends in some measure on the constitution of the patient, but chiefly on the severity of the pain to be prevented. It is in accordance with what is observed in medical and surgical cases, that the pain should be removed in some instances without abolishing consciousness, and that in other instances it should not; for, in certain cases of neuralgia, the pain is so severe, that no material relief can be obtained by chloroform as long as consciousness is retained; and in surgical operations, although it now and then happens that the minor and concluding parts of an operation, such as tying vessels and introducing sutures, can be performed without pain, whilst the patient is consciously looking on, a free incision in the skin can hardly ever be made under similar circumstances without pain.

The external evidences of the uterine contractions continue as before, when the patient is rendered unconscious by chloroform; and the muscles of respiration are called freely into play, to assist the action of the uterus in the second stage of labour. The aspect of the patient under these circumstances, is generally that of one who is suppressing the expression of her sufferings; and any relative or friend who comes in, without knowing that chloroform has been given, begins to praise the unconscious patient for her fortitude. On some occasions, indeed, there are groans and cries, as of suffering; but the mind being unconscious of pain, it can hardly be said to exist.

It may be remarked, that complete anæsthesia is never induced in midwifery, unless in some cases of operative delivery. The diminution of common sensibility to a certain extent, together with the diminution or removal of con-

sciousness, suffice to prevent the suffering of the patient during labour; and she never requires to be rendered so insensible as in a surgical operation, when the knife may be used without causing a flinch or a cry. The nerves of common sensation must be allowed to retain their functions to a certain extent during labour; otherwise the assistance of the respiratory muscles, which consists of reflex action, or "motion arising from sensation, without the aid of volition", would not take place, even if the contractions of the uterus should still continue.

The effects of chloroform on the brain should not be carried during labour beyond what I denominate the second degree of narcotism, or that condition in which the mental functions are diminished, but not altogether suspended, except when the effect of the vapour is associated with natural sleep. The patient under the influence of chloroform to this extent, has no longer a correct consciousness of where she is, and what is occurring around her, but is capable of being aroused to give incoherent answers, if injudiciously questioned. In this state, the patient will sometimes assist the labour by bearing down voluntarily, if requested to do so, and be otherwise obedient to what is said; and by withholding the chloroform for a few minutes, she at any time becomes quite conscious. As a general rule, it is desirable not to hold any conversation whilst the patient is taking chloroform, in order that her mind may not be excited. The plan mentioned above, of giving the chloroform very gently at first, also has a tendency to prevent its causing mental excitement, the patient coming gradually under its effects. In surgical operations, excitement of the mind can nearly always be avoided by carrying the patient pretty rapidly into a state of insensibility, in which the mental functions are necessarily suspended. But in the practice of midwifery, it is not allowable to cause a state of coma or insensibility, except in certain cases of operative delivery, hereafter to be mentioned.

I nearly always employ, in obstetric cases, the inhaler that I use in surgical operations.* There is not the same necessity for an accurate means of regulating the proportion of vapour in the air which the patient is breathing during labour, where but a trifling amount of narcotism requires to be induced, as in surgical operations, where a deeper effect is necessary; still I find the inhaler much more convenient of application than a handkerchief, and it contains a supply of chloroform which lasts for some time, thereby saving the trouble of constantly pouring out more. When I do administer chloroform on a handkerchief during parturition, I follow the plan I recommended in a former communication on this subject,† of putting only about fifteen minims of chloroform on the handkerchief at one time.

The quantity of chloroform administered during any one pain, never exceeds a very few minims; but the quantity used in the course of a protracted labour is often considerable. Two ounces and a half by measure is the largest amount I have used in one case; but, as the apparatus was used, this quantity would go as far as seven or eight ounces employed in the most careful way on a handkerchief. I have not kept any patient continuously unconscious for more than two hours; and eight hours is the longest time I have had to administer chloroform in any case, but it has been continued for a much longer period without ill effects, by Dr. Simpson and others.

Chloroform can be best applied when there is an additional medical man, who has not to attend to the ordinary duties of the accoucheur; but it can be given very well by the accoucheur himself, so as to save the greater part of the suffering of labour; although he perhaps cannot always administer it in the perfect way in which he could, if he had no other duties to divide his attention.

It is probable that the use of chloroform has no particular influence over the duration of labour, in the whole

* This plan has been described, *Med. Gaz.*, vol. xlii, p. 848.

† *Lond. Journ. of Med.*, vol. i, p. 54. It should be recollected that minims of chloroform are very different from drops; two minims being equal to nine drops from the lip of a small phial.

* *London Journal of Medicine*, vol. i, pp. 54, 576.

number of cases in which it is employed; but individual labours are occasionally either retarded or quickened by it, according to circumstances. In some cases, the chloroform, even when very moderately employed, diminishes both the strength and the duration of the uterine contractions, and prolongs the interval between them, thereby making the labour somewhat longer—a matter of no consequence, however, as the patient is not suffering in any way. In other cases, the inhalation causes the uterine action to become stronger and more regular, by removing the excess of sensibility by which it has been interfered with. This occurs more particularly in the first stage of labour. In some cases, also, the chloroform seems to act as a direct stimulant to the uterine contractions, increasing their force and frequency—a circumstance at which we need not be surprised, when we remember that both opium and brandy, in moderate quantity, often act in the same manner. Chloroform has also the effect of promoting the dilatation of the os uteri in many cases, even when no rigidity exists; and when there is rigidity of the os uteri, the inhalation is of the utmost service, and shortens labour very much. This is the case, also, when there is rigidity of the perineum.

During delivery with the forceps, or by perforation, the chloroform requires to be administered very much in the same way as in ordinary cases. It must be given at each pain, so as to prevent the suffering of the patient without checking the uterine contractions. It generally, however, requires to be given a little more freely than in natural labour. Dr. Murphy has related three cases of delivery by the forceps, and one by perforation,* in which I assisted him, four or five years ago, by giving chloroform and Dutch liquid, which I was trying at that time. The operations were chiefly undertaken on account of deformity of the pelvis; and the patients all recovered very favourably. I have given chloroform in only one case of midwifery in which the knife was used. It was a case of Dr. Murphy's, in which he had to make an artificial os uteri. Of course, under such circumstances the patient is made insensible at the time of operation.

When it is necessary to introduce the hand into the uterus to turn the child, the chloroform requires to be given in a pretty full dose, so as to suspend the uterine contractions; and as soon as the operation of turning is performed, the inhalation should be discontinued for a short time, to allow the action of the uterus to return, and assist in the expulsion of the child. In the autumn of 1849, I administered chloroform in a case of presentation of the shoulder, attended by Mr. French, of Great Marlborough Street, and in a case of presentation of the elbow, attended by Mr. Marshall, of Greek Street, Soho: the operation of turning was performed with singular facility in both cases, although the membranes had been ruptured, and the liquor amnii evacuated some time. The uterus afterwards contracted well in both cases, and expelled the placenta in a few minutes. In a case of natural presentation, in which turning was performed by Dr. Murphy, on account of narrowness of the pelvis, and the impossibility of applying the forceps, the introduction of the hand was difficult from want of space, but the uterus offered no resistance.

In other cases in which it is necessary to introduce the hand into the uterus, chloroform is of equal service. On Dec. 26, 1850, I was requested by Mr. Cooper, of Moor Street, Soho, to assist him in a case of retention of the placenta. The patient had given birth to a child two hours before, and Mr. Cooper had introduced his hand, but had been quite unable to bring away the placenta, on account of firm contraction of the uterus, in a sort of hour-glass form. On the chloroform being administered, the hand was easily introduced, and the placenta detached and extracted. There was very little hæmorrhage. I may here state that I have seen hæmorrhage, to any considerable amount, in only one case in which I have given chloroform, and the patient had suffered from it in some of her previous confinements.

* Observations on Chloroform in Midwifery.

It is often asked, whether the chloroform has any effect on the child. It is quite certain that the foetus must receive a portion of the chloroform into its circulation, as it does of any other medicine which is absorbed into the blood of the mother; and when sulphuric ether was the agent employed, its odour could be perceived in the child's breath after birth. The foetus must therefore be influenced by the chloroform, though generally to a less extent than its mother, as it receives its dose only at second-hand. It has seemed in some cases that the child was less acutely sensible to the cold air than usual at the time of its birth; and when the mother is unconscious from chloroform, I have not seen it kick and scream in the violent way, and grasp the bed clothes with the force, during the first minute after its birth, that is often observed under other circumstances. With these exceptions, no effects of the chloroform on the child can be perceived.

18, Backville Street, June 1st, 1853.

FACTS RELATING TO SCARLET FEVER.

By BENJAMIN W. RICHARDSON, Esq.

(Read before the Epidemiological Society, on Monday, March 7th, 1853.)

It would be, on my part, a waste of time and of words to offer any introductory observations on the importance of the disease "Scarlet Fever", or to expatiate on the propriety of investigating the laws by which it is governed. Premising, therefore, that in this essay all theoretical questions in relation to the disease will be let alone, and that matters of fact only will be introduced, I proceed to direct attention to the following subjects:—

- I. Types of Scarlet Fever;
- II. Occurrence of Scarlet Fever at different Periods of Life;
- III. Prevalence of Scarlet Fever in the Sexes;
- IV. Influence of the Seasons over Scarlet Fever;
- V. Recurrence of Scarlet Fever in the same Person;
- VI. Mortality of Scarlet Fever.

I. TYPES OF SCARLET FEVER.

There is perhaps some excuse for the practice that has sprung up and engrafted itself on the professional mind, of recognising three shades or types of scarlet fever; but there is no excuse or reason why these shades or types should receive distinct names; and I would strongly recommend what has been recommended, I believe, by Dr. Watson, that medical men, in speaking of scarlet fever, whether amongst themselves or with their patients, should drop the terms *scarlatina*, *scarlatina anginosa*, etc., altogether, and should call every case of the affection *scarlet fever*; for the disease is an unit, and should be spoken of as one. If indeed a multitude of cases are brought together, and are closely watched by one observer, the unity of the disease cannot fail to become evident, from the universal presence of several important and special symptoms; and from the non-recurrence, as a general rule, of the disease under any type in a person who has once suffered from it in one or other of its forms.

I must remark, however, that, in practice, certain cases are occasionally met with, resembling scarlet fever in many points, in which it is highly difficult, perhaps impossible as yet, to determine whether or not they are true cases of that disease. Let me, in illustration, give a brief description of two such cases, which have within these last six months fallen under my notice.

A young woman, a servant at an inn, was seized with slight shiverings, sensations of chilliness, weight in the head, and thirst. These symptoms lasted about twelve hours, when the body became covered with a bright red rash, the throat sore, and the tongue loaded with white. She was kept in bed, and ordered a simple diet.

medicine. Twelve hours after the first appearance of the eruption, it had entirely disappeared, and the patient expressed herself as feeling quite well. Three weeks afterwards, however, the same symptoms returned, and passed off as favourably as before, leaving no secondary disease, and giving disease to no one else.

In the second case, the patient, a young married woman, was placed in less favourable circumstances; her room was imperfectly lighted and ventilated, her dwelling badly situated, and her attendants were indifferent nurses. A class of symptoms appeared, precisely analogous at first to those described above; but in this case, as the sore throat and eruption faded, great bodily prostration succeeded, attended with griping pains in the bowels and copious diarrhoea. This patient recovered very slowly, but communicated disease to none, although her children slept in the same bed with her, and an infant was at her breast.

There were no cases of scarlet fever in the neighbourhood of these patients; and it is difficult, I repeat, to say whether the cases really were cases of scarlet fever. The symptoms certainly resembled the symptoms of that disease; while the evanescent character of those symptoms, the sporadic nature of the cases, and the fact that no extension of disease took place from them, would afford ground for supposing that they could not have been true cases of scarlet fever. I leave the question for future consideration.*

II. OCCURRENCE OF SCARLET FEVER AT DIFFERENT PERIODS OF LIFE.

It has long been known, that scarlet fever is a disease to which the young are peculiarly liable. There are many causes for this; but the most important causes are to be found in the following three facts:

1st. That the second occurrence of the disease in the same person is contrary to the general rule.

2nd. That all persons who have not had the disease are, as a general rule, subject to it.

3rd. That the influences which give rise to scarlet fever are always present in a greater or in a lesser degree.

To answer fully, and from statistical data, the question, At what periods of life is scarlet fever most prevalent? it would be requisite to collect an immense number of cases of scarlet fever, of all kinds, wherever occurring, and however terminating; to obtain the age of every patient included in those cases; and then to ascertain the numbers affected in the different years of life.

Owing to the slight degree of attention that has been paid to such investigations, it is at the present time impossible for the most earnest epidemiological inquirer to construct a table of cases so occurring, extensive enough to set the question now under consideration at rest; but, from my own report book, from the weekly return books of three medical gentlemen holding parochial appointments,† and from the printed returns of two other gentlemen‡ who made statistics from cases of scarlet fever observed by themselves in Birmingham, in the years 1832 and 1835, I have been able to collect accurate records of 431 cases of scarlet fever, which supply the following information:—That, from the first year of life to the tenth, the liability to scarlet fever gradually increases; and that, after the tenth year, the liability decreases remarkably, and continues to decrease in proportion to the advance of life. Thus, out of the 431 cases referred to, no fewer than 329 occurred in children under ten, and 102 only at ages past that point.

These results were, however, so small, and, as a matter of course, so unsatisfactory to me, that I was led to search for information in another direction. The mortality-tables of

the Registrar-General were, it appeared to me, worthy of considerable regard; for, although it might be objected, that, in a few cases, the mortality of a disease was no sure indication of the number of persons attacked, the objection would be modified, and perhaps removed altogether, if multitudes of cases were consulted, as they might be in the reports alluded to. The subjoined tabular statement shows, in mean results, the proportion of deaths from 31,744 cases of scarlet fever, occurring in Manchester in the year 1839, in Liverpool in 1839, in Birmingham in 1839, in twenty-four town districts in 1840, in London in 1842, 1843, 1844, 1845, 1846, 1848, and in England in 1847.*

Total number of deaths.	Under 5.	5 and under 10.	10 and under 20.	20 and under 40.	40 and upwards.
31,744	21,469	7756	1755	552	212
Per cent.	67.63	24.43	5.52	1.73	0.66

These results are very striking, and afford, I imagine, a near approximation to truth, on the question of the occurrence of scarlet fever at different ages. They corroborate, too, the inferences drawn from the 431 cases before described.

In reading over many of the valuable treatises on scarlet fever which enrich so much the medical literature of this and of other countries, I found more than one eminent author making the assertion, that children under two years of age, and babes at the breast, were not subject to attacks of the disease. The illustrious Withering spoke positively on this subject; and Dr. Nieuwenhuys, an Amsterdam physician, and the author of an admirable paper on small-pox and scarlet fever, expresses, in an indirect manner, a similar opinion; and intimates that, on two occasions, he saw "infants escape, whose mothers were suffering heavily under the disease, and who suckled them from time to time".

Now, if the opinion, that infants are not subject to scarlet fever, were correct, it would embody matters of great interest and importance, physiologically and practically. I have therefore conceived that it would be no lost labour to settle the question by reference to facts.

The following particulars have been obtained, and are amply sufficient to disprove the assertions of Withering, and of the other writers who have either accepted his views, or offered similar ones independently of his labours:—In 242 cases, occurring, some under my own observation, and others under the observation of the gentlemen to whom I before referred, cases the majority of which recovered, and in which all ages are included, not less than fifteen were in infants under two years of age. The reports of the Registrar-General also afford good evidence on the question now in hand, inasmuch as these reports may be positively relied on for the present inquiry, and include great numbers of cases. The results derived from these returns are as follow.

Out of a total of 12,962 deaths from scarlet fever in children under five years of age, occurring in the county of Kent in 1843, in London in 1845, 1846, and 1848, and in England in 1847, there were—

Age.	No.	Age.	No.
Under 1 year	1289	Over 2 and under 3	3338
Over 1 and under 2	2674	Over 3 and under 4	3063
		Over 4 and under 5	2398
Total under 2 years	4163	Tot. from 3rd to 5th yrs.	8799

Total from 1 to 5 years, 12,962.

Thus, out of these 12,962 deaths in children under five years, there were, in the first two years, no fewer than 4,163 deaths from scarlet fever.

* At the same meeting of the Epidemiological Society at which this paper was read, another paper on "Scarlet Fever", from Mr. Bower Harrison, was also read. Curiously enough, Mr. Harrison alluded to several cases very similar to those described above, and seemed, like myself, to be in doubt as to their true nature.

† Mr. Browne, of Saffron Walden; Mr. Palmer, of Sheen; and Mr. Beresford, of Northborough, Leicestershire.

‡ Messrs. Byland and Parsons.

* At the meeting of the Epidemiological Society, the above and all the following tables were exhibited in detail. For the most valuable aid in the calculations required for the construction of these tables, the writer is deeply indebted to his friend Mr. Adolph Leipner.

I have one other calculation (No. III) bearing on this subject. In a total of 3,795 deaths in patients under five years, occurring in the London hospitals, in Manchester, and in Birmingham, in the year 1839, in 24 towns in 1840, and in London in 1842, there were—

Age.	No.	Total.
Under the second year	410	3795
Over the second, and under the third :	1797	
Over the third, and under the fifth	1588	

I need not comment on this table. The results are similar to the previous one, and both indicate plainly that infants are highly susceptible to scarlet fever.

III. OCCURRENCE OF SCARLET FEVER IN THE SEXES.

Up to the present time, almost all writers on scarlet fever have expressed an opinion, that it is a disease most apt to attack the female sex. Dr. Tweedie says, arguing on his own general experience, and on the results of an imperfect table, "that females are more subject to the disease than males": with great candour, however, he repeats the opinion of Withering, viz., "that, in children, the number of sufferers are equal in both sexes; but, amongst adults, females suffer most". Fothergill, in writing of the malignant attack of scarlet fever which visited London in 1749, says, a greater number of girls have it than boys, more women than men; Rayer affords similar testimony; but Dr. Binns, in describing an epidemical scarlet fever which occurred in the Ackworth school, tries to show, by reference to a small, but, as far as it goes, fair table of cases, that girls are less susceptible to the disease than boys.

The 431 cases in my own possession, and to which I have before drawn attention, are not sufficient in number to afford anything like satisfactory evidence on the subject. As far as they do extend, however, they show an equality, in the matter of susceptibility to the disease, between the sexes, subject to certain laws, which will be better understood when the subjoined figures have been consulted.

I find, from the Registrar-General's reports, that, out of 102,382 deaths from scarlet fever, occurring in England in the years 1838, 1839, 1840, 1841, 1842, in London in 1842, 1843, 1844, 1845, 1846, and in England in 1847 and 1848 there were—

Amongst males, 51,660 }
 „ females, 50,722 } = 102,382 (938 males in excess.)

This calculation takes in sufferers of every age, and leaves, at first sight, a fair inference on the mind, that males are, on the whole, more subject than females to scarlet fever. To understand the question fairly, however, we must analyse a large number of cases, and find at what ages the deaths occurred.

Below, 31,744 cases of death from the disease, occurring in Manchester, Liverpool, and Birmingham, in the year 1849, in 24 towns in 1840, in London in 1842, 1843, 1844, 1845, 1846, and 1848, and in England in 1847, have been analysed; the relative number of deaths in both sexes, and in certain specified periods of life, being given (Table No. v).

Age.	M.	F.	Total.	Predominance.	
				M.	F.
Under 5 years	11097	10372	21469	725	—
From 5 to 10	3927	3829	7756	98	—
„ 10 to 20	844	911	1755	—	67
„ 20 to 40	261	291	552	—	30
„ 40 & upwds.	97	115	212	—	18
Total	16226	15518	31744		

From this statement, we derive the general fact that, under the age of ten, more males die from scarlet fever than females; but that, above ten, the contrary obtains.

In the next statement, the relative mortality in the sexes, in a given number of deaths from scarlet fever, is stated, together with a reference to the population of the districts in which those deaths occurred.

In the districts of Kent, in the year 1843, there were—

Deaths at all ages, 413 { 205 males } 3 females in excess.
 { 208 females }

The population of these districts, as obtained by the census taken rather more than a year before, was—

Pop. in 1841, 469,113 { 232,228 males } 4,657 fem. in excess.
 { 236,885 fem. }

This last table is, it will be seen, quite contrary to the first in its results; and separate writers, inclined to controversy, might, by referring to only one of these tables, baffle an adversary considerably. Considered, indeed, in their singleness, the tables might and would be made to convey the most incorrect ideas. But when the three tables given are viewed carefully, and with an unbiassed eye, their very differences are found to be of the highest value, inasmuch as these differences place before the mind the true state of matters. Collectively, then, the calculations indicate, I believe, that scarlet fever makes no selection as regards sex, but attacks more males, or more females, according to the relative number of males or females who are resident in any district where it is epidemical.

The last table illustrates this fact exceedingly well. There are more deaths from scarlet fever amongst females in a given portion of country than amongst males; and there are in the same portion of country, previous to the scarlet fever epidemic, a larger number of females than of males in the population.

The table in which ages are specified conveys a similar lesson, when the general laws of population are understood. In the child part of our population—using the word population in its general sense—males preponderate; but in the youth and adult population, there are more females than males, owing to the fact, that youths and men are exposed to more causes of mortality, and are drafted into other countries in larger numbers, than girls and women. Now, the mortality of scarlet fever, as the results given above illustrate, seems to follow this law of number; for our tables show, that whilst more males die under ten years from the disease than females, after the age of ten the mortality begins to take the lead on the female side, and to continue steadily to do so as life advances.

Still more our calculations from the Registrar-General's Report show the same fact; for what can the large preponderance in the deaths of males arise from, except from the circumstance, that at the period of life when the body is most susceptible to the disease (the first ten years), the male population is larger than the female?

I cannot fail to remark, also, that the calculations on which these last conclusions are based, illustrate, although made from mortality returns, the prevalence of the disease in the sexes in all classes of cases; for one cannot but suppose that if females were more subject to the disease than males, the results of the mortality tables would be widely different to what they are, seeing that females are naturally less able than males to bear up against so dangerous an affection.

The discrepancies and contradictions of general writers on the subject of sex and scarlet fever are also removed by the views I have ventured to throw out; for as such writers have written of the disease as they saw it in individual cases, without any regard to the relative number of each sex who were subject to its attacks at the time and place, or to the ages of the sufferers, it is quite certain that their mutual statements must differ. Withering, however, seems to have had pretty correct notions on the subject, when he said, that in children the number of boys and girls who died from scarlet fever was nearly equal, but that females were

number of female patients considerably exceeded that of the male.

IV. INFLUENCE OF THE SEASONS OVER SCARLET FEVER.

I think that, in collating the facts which may be obtained on the subject of scarlet fever, it is possible to show that the disease is influenced by the seasons. The concurrent testimony, in fact, of almost all writers on the disorder, teaches that it is most common in autumn, next so in the summer, next so in the winter, and least so in the spring. In three epidemics which I have witnessed in different parts of this country, the disease has always commenced in the summer, become most violent in the last months of the year, has continued into the new year, and died away with the spring. I believe, too, that sporadic cases are most common in autumn, although I have seen such instances in the month of April. Cases, however, occurring in the spring, even though of malignant character, are more likely to recover than at the other seasons.

I could bring forward several authors, whose testimony is valuable on the question of season in relation to scarlet fever. As the subject is important for numerous reasons, it may not be wrong to refer to some of these authorities.

Sydenham remarks that scarlet fever, though it may occur at other seasons, is most common in the end of summer, when it attacks whole families, and children especially. Fothergill, in describing the malignant form of scarlet fever, observes, "that although it survives different seasons, and all varieties of weather to which we are exposed, yet it seems to show itself most frequently in the autumn, and in the beginning of the winter; at least I have met with more cases from September to December inclusive, than in all the other months together."

Cullen names the beginning of winter as the time when scarlet fever is most prevalent. Withering speaks of the winter and summer months as favourable seasons, and records the particulars of an epidemic which, commencing in summer, was temporarily checked in October, but recommenced, with extreme virulence, in November. The epidemic of malignant scarlet fever that raged in St. Albans, in 1748, is described by Dr. Cotton as occurring in the latter end of the year. The epidemic recorded by Dr. Peart in 1802, did not become violent and extensive until the latter part of August and in September. Willan remarks that the disease, scarlet fever, is most virulent during October and November. Haygarth entertained a similar opinion. Rayer observes that the disease is most common about the equinoxes. An epidemic of malignant scarlet fever, described by Chomel under the title of gangrenous sore throat, and which raged in Paris a hundred years ago, was most violent in the months of October and November. Dr. Nieuwenhuys, in his paper on "the scarlet fever in Amsterdam, in the year 1834", remarks, "the disease first showed itself, in the epidemic form, in the month of June 1834, and its victims were—in June 22, in July 32, in August 50, in September 78, in October 136, in November 106, and in December 61."

Mr. Ryland, in describing the cases of scarlet fever which occurred under his care amongst the out-patients of the Birmingham Infirmary, in the year 1835, states that in the first quarter of the year ending March 25th, he had 5 patients, in the second quarter 7, in the third quarter 35, and in the three last months 59, making 106 cases in all.

Finally, Dr. Tweedie, in his essay on Scarlet Fever (many other authors being omitted), states that the disease is most common in autumn, least so in spring.

Such are some of the conclusions to which general observers have come with reference to the prevalence of scarlet fever at the various seasons of the year; and when these conclusions are tried by statistical facts, their correctness is strikingly established.

In 46,077 deaths from scarlet fever in London in the years 1838, 1839, and 1840; in England in 1841 and 1842; and London in 1843, 1844, 1845, 1846, 1847, and 1848, the

proportions of deaths in the seasons of those years run as follows:

	1st quarter. Jan. Feb. Mar.	2nd qr. April, May, June.	3rd qr. July, Aug. Sept.	4th qr. Oct. Nov. Dec.	Total.
No. of deaths .	10465	9068	11914	14630	46077
Per centage .	22.711	19.679	25.856	31.751	

The above table requires no comment. Derived from an immense number of cases, the inference to which it leads, viz., that scarlet fever is most prevalent in this country in the three last months of the year, least so in the months of April, May, and June, is obvious. One word I must add. If the reader could see an analysis of the above tabular statement, he would find that the rate of mortality is not always the same in the special quarters of the years specified. So that a calculation made from one or two, or even three, of those years, would be likely to lead into a grievous error. When, however, the trouble is taken to reduce the returns of a great number of years to a single calculation, one approaches at least to the truth.

I do not apologise for this digression, because nothing is more important to the epidemiological inquirer than the possession of accurate and extensive statistics. An indolent or an unconscious statician is a literary *ignus fatuus*. The indolent statician will give loose and insufficient statements; the unconscious one can and will prove anything to suit his own purpose. Both would be much more usefully and worthily employed in picking oakum than in penning figures.

V. RECURRENCE OF SCARLET FEVER IN THE SAME PERSON.

In the history of diseases, there is scarcely a more interesting or striking fact than that there should be a certain class of diseases which, as a general rule, do not occur a second time in the same individual. Physiologically, pathologically, and practically, the fact is interesting, and deserves to be made a subject for special study. On the possibility of the recurrence of scarlet fever in the same person, opinion has been divided. The well-known assertion of Willan, that out of two thousand cases of the disease, he had never met with one in which it had happened for the second time in the same person, has been transcribed by almost all writers, and has led many to entertain a belief that the disease could never occur twice in one individual. This belief, however, is quite erroneous. Rayer saw one well-marked instance of recurrence; Bateman and Withering saw several; Blackburne saw two such cases; and Dr. Tweedie observes—"We certainly have met with several well-authenticated instances of a second attack of scarlatina in the same person. Speaking generally, I may say that I have seen second attacks of scarlet fever in the same person on three or four occasions. For particular evidence, the following cases may suffice. A little girl whom I attended in 1850, took scarlet fever. The disease was very decided in character, but passed over favourably. A month afterwards, the little patient complained of feeling sick and cold, and it was feared that the symptoms of dropsy were about to present themselves. Instead of this, to the great surprise of every one, the skin a second time became universally red, and the throat sore; and the patient passed again through a most marked attack of scarlet fever."

I am able, too, to speak from experience in my own persons on this subject. When a child, I suffered, as I well remember, from scarlet fever, during a time when it was occurring epidemically in my native village. The rash was universal, and intensely red; the throat sore; the recovery slow. In the spring of 1850, whilst attending cases of scarlet fever, I sickened, became ill, and passed through a very severe second attack of the disease. The skin was again red, the throat sore and ulcerated, and the recovery gradual. Still more curious, whilst attending a boy, in the month of April 1852, who had a severe attack of scarlet fever, I became exceedingly unwell, suffered from shivering,

and sore throat, and had a faint red blush on the chest and neck. I am minute in these particulars, because it is important to settle satisfactorily all points that admit of being settled in epidemiological inquiries; for by such means difficulties are exhausted, and fewer questions are left for investigation. I have not been able to collect statistical information on this subject of recurrence, so that it is impossible to state the frequency of recurrences. That they are rare is evident, for I have not, in reading or conversation, met with a single author or practitioner who had seen a second attack of scarlet fever prove fatal.

VI. MORTALITY OF SCARLET FEVER.

The most important subject in connexion with scarlet fever is its mortality. Every writer on the disease, since its full recognition as a disease, has described, in mournful terms, its frightful ravages. Mr. Kearsley, of Philadelphia, writing about a hundred years since of the disease, as it appeared in America, says, "it baffled every effort to stop its progress, and seemed, by its dire effects, to be more like the sword of vengeance to stop the growth of the colonies, than the natural progress of a disease". And to this day the yearly victims of the disorder are exceedingly numerous in many parts of the world.

In considering the mortality of scarlet fever, several questions force themselves on our notice, some of which have been answered already incidentally. I allude to the subjects of age, of sex, and of season, as influencing the mortality of the malady.

Two questions still remain: first, the influence of locality on the fatality of scarlet fever; second, the relative mortality of scarlet fever in connexion with other epidemical diseases.

To answer these questions, I have merely had recourse to the pages of the Registrar General, and have referred, therefore, only to the disease as it occurs in our own country. The next table shows the comparative mortality from scarlet fever, in towns and rural districts. To insure correctness, each statement of deaths has been obtained from a population of a million.

Year.	District.	Towns.	Country.
1838.	London, 24 towns, and 12 counties	517	202
1838-9.	London and 5 counties	2522	454
"	24 towns and 7 counties	1654	737
1841.	London, 24 towns, and 12 counties	683	684
	Mean from 1838 to 1841	988	478

The mortality from scarlet fever in a million of people is, therefore, rather more than twice greater in towns than in rural districts.

The following table (No. ix) indicates the different rates of mortality *per million* from scarlet fever, in eleven districts of England, during the years 1838, 1839, 1840, 1841, 1842, 1847, 1848. The last column will supply at a glance the comparative rate of mortality.

District.	Deaths in seven years per million.	Relative order.
North Western Counties	10328	1
Metropolis	7838	2
Yorkshire	7018	3
Monmouth and Wales	6609	4
Northern Counties	6428	5
North Midland Counties	6244	6
Western Counties	5013	7
Eastern Counties	4708	8
South Midland Counties	4694	9
South Eastern Counties	4609	10
South Western Counties	4122	11

The above table needs but few observations. It indicates an extraordinary mortality in the north-western counties. The complete table showed that scarlet fever does not fall on the whole country at the same time, but is, at similar periods, absent to a great extent in one locality, and extensively present in another.

The subject of the relative mortality of scarlet fever in reference to other epidemical diseases, possesses peculiar interest; and I have, therefore, taken some pains to illustrate it by several tables. The following (No. x) shows the relative mortality of seven epidemical diseases. The returns are, for England in the years 1838, 1839, 1840, 1841, and 1842, and for London in 1843. The calculations are based on the numbers of deaths in a population of a million, as in a previous table.

Diseases.	No. deaths.	Rel. order.
Typhus	6442	1
Scarlet Fever	4015	2
Hooping Cough	3540	3
Measles	3480	4
Small Pox	3183	5
Erysipelas	488	6
Influenza	395	7

Total 21549

In special years, the relative position of these mortality figures is somewhat changed.

In the next table, the relative mortality in a total of 79,256 deaths from six epidemical diseases, occurring in London during the period of twelve years, from 1840 to 1851, is exhibited:

Diseases.	No. deaths.	Rel. order.
Typhus	23064	1
Scarlet Fever	21551	2
Measles	15400	3
Small Pox	10710	4
Erysipelas	4276	5
Influenza	3295	6

Total 79250

In the following and final table the subject of relative mortality is carried further, by a calculation based on 462,227 deaths from seven epidemical diseases, occurring during a period of eleven years, viz., in England in 1838, 1839, 1840, 1841, 1842, in London in 1843, Kent in 1843, in London in 1844, 1845, and 1846, and in England in 1847 and 1848:—

Diseases.	No. deaths.	Rel. order.
Typhus	141,517	1
Scarlet Fever	105,250	2
Measles	63,793	3
Hooping Cough	62,867	4
Small Pox	50,400	5
Influenza	18,553	6
Erysipelas	10,787	7

Total 462,227

Thus, the three tables I have given all prove that scarlet fever, in its rate of mortality, is second only to typhus fever.*

Before I conclude, I shall devote a few moments to a re-statement of the conclusions at which I have arrived. These conclusions are six in number, viz.:

1st. That scarlet fever, in whatever form or type appearing in individual cases, is a single disease in its universal character, and should have only one name.

2nd. That, after the first ten years of life, the liability of an individual to an attack of scarlet fever lessens in proportion to his increase of years.

3rd. That scarlet fever pays no respect to either sex, but

* In the discussion that followed the reading of this paper at the Epidemiological Society, I stated, in answer to a question by the president, that scarlet fever was in all probability a more fatal disease than even typhus fever; inasmuch as the word typhus was often unjustly returned, in cases of death from pneumonia and other diseases, which assume in their last stages what is absurdly called the "typhoid type". In this opinion, Drs. Snow, Sibson, and many other fellows of the Society concurred.

attacks more or fewer of males or of females in a district or country, according to the relative differences in the number of the sexes in those districts or countries.

4th. That the seasons influence the spread of scarlet fever; the disease being most prevalent in the three last months of the year; least so in the months of April, May, and June.

5th. That scarlet fever may occur twice in the same person; that such recurrences are very rare, and never, as far as can yet be ascertained, fatal.

6th. That the mortality of scarlet fever is greatest in children under ten years of age—is equal in the sexes—is highest in the three last months of the year—is, as a general rule, twice as great in towns as in rural districts; and is second in extent only to typhus fever of all the ordinary epidemic diseases.

On this occasion, it has been my earnest endeavour to gather from every trustworthy source to which access could be obtained, such particulars concerning scarlet fever as admit of being styled *matters of fact*; to place these particulars side by side; to compare the one with the other; and, in the end, to draw those inferences from them which were to my unbiassed judgment the nearest to the truth. If anything has been written that may be considered as differing from received opinion or dogma, I can only observe, that such differences have arisen out of the mode of inquiry that has been pursued, and that they are not differences made for the sake of difference; while, on the contrary, if it should occur to any one that certain subjects, already well known, have been restated with too much emphasis of thought, I remark that such restatements, as they have now been made, prove, on *particular evidence*, facts which had before been recorded only from general observation; and that

"Truth can never be confirmed enough,
Though doubts did ever sleep."

Mortlake, April 1853.

[Along with the manuscript of Mr. Richardson, we received the twelve elaborate tables by which he illustrated his paper when it was read before the Epidemiological Society. We much regret that it is impossible for us to publish these tables *in extenso*, from the great amount of space which they would occupy. To prevent confusion we have also omitted the references to the tables by their numbers, as without the tables themselves these references would convey no instruction. EDITOR.]

PERISCOPIC REVIEW.

SURGERY.

EXCISION OF THE KNEE-JOINT.

A VERY interesting paper, on excision of the knee-joint, has been published by Dr. R. J. MACKENZIE of Edinburgh, in the *Monthly Journal of Medical Science* for June 1853. He says that an impression, most unfavourable to its performance, appears to have been generally entertained; but that, from what he has lately seen of its results in several cases, he is convinced that it has been rejected from surgical practice on insufficient grounds, and that it will yet come to supersede, in many cases, amputation of the thigh.

The author gives an account of the cases in which the operation is known to have been performed.

CASE I. Mr. Filkin, of Northwich; in 1702. No satisfactory record of the case exists.

CASE II. Mr. Park, of Liverpool; in 1783. A year after the operation, the patient could walk with great ease and firmness, without the assistance of a stick or any splint; the foot being three quarters of an inch shorter than the other. Seven years later, Mr. Park reports that this patient had been able to perform all the duties of a seaman; but had been drowned by the upsetting of a flat in the Mersey.

CASE III. Same operator. The patient, a very unfavourable subject, died in about four months.

CASE IV. Moreau, some time afterwards. The patient was apparently going on very favourably, when epidemic dysentery

appeared in the hospital; and he was attacked by it, and died three months and a half after the operation.

CASE V. Moreau. The operation was fatal.

CASE VI. Moreau, junior. The patient recovered with a serviceable limb.

CASE VII. Mulder, in 1800, excised the knee-joint of a pregnant female. Two months after the operation, she was delivered of twins, and some time afterwards died of tetanus.

CASE VIII. Mr. (now Sir P.) Crampton, in 1823, removed the patella, part of the tibia, and upwards of six inches of the femur. The patient lived upwards of three years after the operation, and then died of phthisis.

CASE IX. Mr. Crampton, in the same year, operated on a girl. Six months after the operation, the femur and tibia were consolidated by a firm bony union. Upwards of three years after, Mr. Crampton states that the femur and tibia were firmly consolidated; the leg and thigh were not in the slightest degree wasted, but the limb was considerably bowed outwards; and she was able to stand or walk for a considerable time.

CASE X. Mr. Syme, in 1820 and 1830, excised the knee-joints of two children between seven and eight years of age. In 1831, Mr. Syme described the limb in the first case as "stout and well nourished, and, though slightly bowed outwards, not occasioning any disagreeable deformity: it allowed a slight degree of flexion and extension". The heel merely of the shoe was required to be two inches higher than the other. In 1840, however, Mr. Syme says of this case, that "in course of time it was found that the growth of the two limbs was not equal, and that the one which had been the subject of operation gradually diminished in respective length, until it wanted several inches of reaching the ground when the patient stood erect."

CASE XI. Mr. Syme, in 1830. The patient, a child, died about ten days after the operation.

After this, excision of the knee-joint seems to have been abandoned till within the last three years. Of eleven cases, six had died, and five had recovered. Excluding the cases of Mulder and Mr. Crampton, and Moreau's first case, the result in the remaining three fatal cases was attributable to the direct effects of the operation. Of the five cases which recovered, the limb was thoroughly serviceable in three; the amount of usefulness in the fourth case is unknown; and in the fifth case (Mr. Syme's) the limb was ultimately useless.

In 1850, the operation was revived by Mr. Fergusson; and within the last three years it has been performed thirteen times; in three cases by Mr. Fergusson, in six cases by Mr. Jones of Jersey, in one case by Mr. Page of Carlisle, in one case by Dr. H. Stewart of Belfast, and in two cases by Dr. Mackenzie. Of the thirteen individuals, three have died; two directly from the effects of the operation, and one from dysentery. The remaining ten are, so far as Dr. Mackenzie knows, alive. In five, the limb is used freely in progression; in one, the result, as regards usefulness, is as yet uncertain; in one, Dr. Mackenzie is ignorant of the result; in the remaining three, the most favourable expectations may be entertained.

The following is an abstract of the recent cases:—

CASE XII. Mr. Fergusson operated, July 20, 1850. The patient, a male, aged 21, died on the ninth day, from acute necrosis of the femur.

CASE XIII. Mr. Fergusson, October 30, 1852. The patient was a female, aged 21. Considerable constitutional disturbance followed, and convalescence was protracted by erysipelas. Six months after the operation, there were one or two small sinuses in the neighbourhood of the wound. The limb was shorter than its fellow by about three inches, and slightly bowed outwards at the knee. Slight motion (chiefly antero-posterior) existed between the bones. The patient appeared to be going on favourably.

CASE XIV. Mr. Fergusson operated, April 2, 1853. The patient, a female, aged 28, died with all the symptoms of pyæmia, sixteen days after the operation.

CASE XV. Mr. Jones operated, January 19, 1851, on a female, aged 25. Dr. Mackenzie visited Jersey for the purpose of witnessing the results of Mr. Jones's cases; but, as this patient lived at a distance from St. Heliers, he was unable to see her. From an account furnished by Mr. Jones, however, it appears that the shortening of the limb is a little more than three inches, and that, complete anchylosis not having taken place, the patient requires a support on the inner side of the bone. With this she can move about freely, and stand for hours together.

CASE XVI. Mr. Jones operated, April 27, 1851, on a boy eleven years old. The case seems to have been peculiarly unfavourable. Before the operation, the leg (left) was fixedly flexed on the thigh: the boy was emaciated, and numerous

sinuses in the leg and thigh communicated with the diseased bones. Nearly five inches of the femur and tibia were removed. On April 21, 1853, when Dr. Mackenzie examined him, he appeared in perfect health; and the limb was sound, though numerous cicatrices existed. Complete ankylosis had taken place, the limb being a little bowed outwards, and slightly flexed at the knee. The shortening of the limb was rather under four inches; the muscles were well developed; and the boy could walk and run quickly, and stand on the limb alone. No measurement had been made; but, from an examination of the apparatus which had been used, and the convictions of Mr. Jones and the nurse, Dr. Mackenzie was satisfied that the limb had grown upwards of two inches since the operation was performed.

CASE XVII. Mr. Jones operated, September 4, 1851, on a lady, aged 30. Everything went on favourably for eight days, when the patient was attacked with epidemic dysentery, and died on the fourteenth day.

CASE XVIII. A boy, aged 7, was operated on by Mr. Jones, fifteen months ago. The condition previously to the operation, and the results, are very similar to those of case xv.

CASE XIX. This patient, a male, aged 20, was operated on by Mr. Jones, about November 1852. When Dr. Mackenzie saw him, there was shortening to the extent of rather less than an inch and a quarter. He walked with crutches, but could, though not yet easily, walk without them. Dr. Mackenzie has since heard, from Mr. Jones, that this patient is progressing rapidly.

CASE XX. Mr. Jones operated on a boy, aged 9, on April 17, 1853. The patella was not removed; its carious surface having been taken away by the gouge. The head of the tibia and condyles of the femur were removed without division of the tendinous or the ligamentous attachments of the patella. Four weeks after the operation, the patient was progressing most favourably.

CASE XXI. Mr. Page of Carlisle excised the patella, and two and a half inches of the femur and tibia, in a lad aged 17, on June 7, 1852. Eleven months after the operation, there was shortening to three inches; the bones were completely ankylosed; the patient could walk a short distance without a stick, and was daily gaining strength.

CASE XXII. Dr. H. Stewart of Belfast has performed the operation within the last few years; but nothing more is known of the case than that the result is very encouraging.

The above are the cases of which Dr. Mackenzie has been able to find records, or to obtain accounts. The following is an abstract of the history of the two cases in which he himself operated:—

CASE I. W. H., aged 42, an hostler, from Carlisle, came under Dr. Mackenzie's care in the Royal Infirmary of Edinburgh, Sept. 28, 1852. He was suffering under disease of the left knee-joint, of five years' standing. The symptoms were uniform thickening of the parts around the knee, and severe gnawing pain, especially during the night, much aggravated by the slightest motion. Considerable relief was obtained by the joint being kept immoveable in leather splints, and by the repeated application of the actual cautery. The thickening became diminished. A painful spot, however, remained over the inner side of the head of the tibia, on account of which the counter-irritation and the leather splints were continued. He continued in this condition till about the middle of January, when, without assignable cause, the pain in the knee, especially on each side of the head of the tibia, became so severe and constant, that, in spite of the free and frequently repeated use of morphia, he scarcely slept night or day. The swelling of the joint again increased, and the foot and leg became oedematous. On the 26th of January, Dr. Mackenzie called a consultation, as it appeared to him that the removal of the disease by operation was alone likely to save the patient. It was thought, however, that a repetition of the same measures as had been already adopted might still save the joint. No relief, however, was obtained; and, after ten days' further delay, he yielded to the solicitation of the patient to remove the disease by operation.

The operation was performed, February 5, 1853. A straight incision was made across the front of the joint, a little below the level of the patella, and rather less than half round the limb; and, at right angles to each end of this transverse incision, a longitudinal incision of about two inches in length gave the wound somewhat the form of the letter H. The operation was performed according to the plan of Moreau; the patella being first removed, then the condyles of the femur, and lastly the articular surface of the head of the tibia. It was accompanied by smart hæmorrhage from the articular arteries, which was at

once arrested by applying ligatures. On dividing the tibia with the saw, the cavities of two abscesses in the cancellated texture of the bone were laid open, each of a size capable of containing a grape. Dr. Mackenzie carefully removed the remaining portion of the walls of these abscesses with the gouge, and then, finding that the diseased portions of bone had been entirely removed, he placed the ends of the tibia and femur in apposition, united the wound by sutures, and fixed the limb in the straight position, by applying a splint on its posterior surface.

The articular surfaces of the bones were found almost entirely deprived of cartilage; and both the cancellous and the laminated structure of the bones, at various points, were in a state of suppuration and caries. The primary disease evidently consisted of suppuration of the cancellous texture of the head of the tibia. The extent of bone removed in the operation amounted to rather more than two inches—an inch and a half of the femur, and a little more than half an inch of the tibia.

The subsequent progress of the case is expressed in the following summary.

"The patient was suffering under a high degree of irritative fever at the time of the operation. He suffered, from the third to the tenth day following the operation, from severe and incessant hiccough, which, as the subsequent symptoms proved, was referrible to a local source of irritation on the surface of the diaphragm. From the end of the second to the seventh week, he suffered from nearly constant diarrhoea, evidently dependent on hepatic derangement of a serious character, and of old standing. Two months after the operation, he passed safely through a severe attack of pleuro-pneumonia; and in spite of all these untoward complications, the wound, at the end of three months and a half after the operation, was, with a trifling exception, entirely healed, and the bones consolidated, though not quite immoveable, in a nearly straight position."

CASE II. I. J., aged 28, a fisherman from Shetland, was admitted under Dr. Mackenzie's care on February 14, 1853. He was suffering from disease of the knee-joint of about ten months standing. The affection had commenced, without any assignable cause, by pains and swelling of the joint, which gradually increased; and, for two or three months previously to his admission, had entirely disabled him from moving about. The pain was considerably mitigated by the joint being kept immoveable in leather splints, and by the repeated application of blisters. About a month after his admission into the hospital, the pain again became more severe, and was referred chiefly to the outer side of the head of the tibia. The actual cautery was freely applied, but without relief; while increasing deformity of the joint, and pain on slight motion, gave evidence of the morbid changes which were in progress in and around the articulation. Shortly after this he had an attack of modified small-pox, from which he speedily recovered. No improvement, however, took place in the condition of the joint. He continued to lose flesh; the pain and the deformity increased; and symptoms denoting suppuration of the joint presented themselves.

Sir George Ballingall, Dr. Dunsmure, and Dr. Gillespie, who saw the patient with Dr. Mackenzie on the 2nd of May, agreed with him in the necessity of performing amputation, or excision of the joint, to either of which measures the patient gave his consent.

Dr. Mackenzie excised the joint on the 5th May, 1853. Having found the disadvantages of the H-shaped incision, he exposed the interior of the joint by a semi-lunar incision, from the inner side of the inner condyle of the femur to a corresponding point over the outer condyle, the incision passing in front of the joint nearly as low as the tuberosity of the tibia. The flap thus formed was dissected back, the ligamentum patellæ being divided, and the patella left in the substance of the flap. The rest of the operation was completed as already described; but the patella was left in its place, and its immediate attachment left undisturbed. The cartilage which remained on its surface was removed by the gouge, as well as the rough surface of bare bone around its articular margin. The bleeding was very trifling: one of the articular branches and several small vessels were secured by ligature, and the wound was dressed and the limb supported as already described. The interior of the joint presented the usual advanced strumous disease of the synovial membrane, suppuration of the joint, universal thickening and degeneration of the membrane, and ulceration of the margins of the cartilage in nearly their entire extent. Great part of the cartilage covering the articular end of the bone was as yet unaltered. Three-fourths of an inch of the tibia, and fully an inch and a half of the femur, were removed.

When Dr. Mackenzie wrote the paper of which this is an

abstract, the patient, a little more than a fortnight after the operation, was going on favourably.

REMARKS. On the subject of excision of the knee-joint, Dr. Mackenzie makes the following observations:—

"The propriety of attempting to save a limb by excision of the knee-joint seems to depend on the three following considerations:—1st. Is the operation of excision attended by greater or less danger to life than amputation of the thigh? or, may the dangers of the two operations be considered equal? 2nd. In the event of recovery after excision of the knee-joint, is the limb more or less useful and seemingly than a wooden leg? 3rd. Does the long confinement to the horizontal posture, which is necessary after excision of the knee-joint, in any measure counterbalance the benefits of the operation (if such benefits are proved) as compared with amputation of the limb?

"A careful consideration of these questions, and of the recorded results of the operation, led me, several years ago, to doubt the propriety of the operation having been rejected from surgical practice. I satisfied myself, by repeated trials on the dead body, that the operation could be performed without difficulty, and without the risk of wounding any important parts; and, as a teacher of surgery, I have been in the habit of mentioning to my pupils my impression that the operation had been rejected from practice on insufficient grounds.

"With regard to the considerations which I have suggested as principally bearing on the merits of the operation, I would submit,—1st, That the danger of the operation may be reasonably expected to be less than that attending amputation of the thigh. The wound necessary for the removal of the diseased bones is less extensive than the wound of amputation of the thigh, whether performed by the circular or flap operation. The large vessels and nerves are not divided in the operation, the parts involved in the incisions being principally the integuments and ligamentous apparatus of the joint; the medullary canal of the bone is not laid open, a point which has of late years been suggested as of some consequence in diminishing the dangers of amputation; the shock, which always attends the sudden removal of a large part of the body, is avoided.

"Time and experience, however, can alone determine the comparative danger of the two operations. In the mean time, the results of the limited number of cases in which the operation has been recently practised, prove, as far as they go, that the danger to life is not great; and, unless some unforeseen accident should occur to the cases, which are at present in progress of convalescence, that the danger is inferior to that of amputation.

"2nd. With regard to the usefulness and the seemliness of the limb, I need only refer to the account I have given of the results of the operation in Mr. Jones' hands, to show that the limb may retain a degree of usefulness which can never be attained by the wooden leg in common use, nor yet by the most expensive and efficient artificial limb which I have ever seen; and if, in the days of Mr. Park, such a result could be obtained as that a man, whose knee-joint had been excised, could run up the rigging, and perform all the duties of a seaman, surely, with all the resources of modern surgery, we ought to obtain an equally satisfactory result now.

"3rd. The remaining objection to the operation is the tediousness of the convalescence. This, I think, unquestionably detracts, to a certain extent, from the benefits of the operation. I am doubtful, however, after all, whether the recovery can be proved to be, on the whole, more tedious than the recovery from compound fracture of the leg; in some cases, even the limb seems to have been restored to usefulness as soon as the patient would have been able to walk on a wooden leg, had the limb been amputated. In Mr. Syme's case, for instance, 'in the course of four weeks after the operation, the wound was all but healed, and the limb, before the expiration of three months, had regained so much strength, that the patient could make some use of it in walking.'[†]

"Mr. Syme, in another place, says—'It ought to be recollected, too, that, though recovery from amputation of the thigh is usually completed in three or four weeks, it is generally at least as many months before the patient can rest the weight of his body on the face of the stump, so as to use it in standing or walking.'[†]

"Another objection has been brought forward against the

operation, which requires to be noticed; viz., that when the operation has been performed on children, the growth of the limb has been checked, and that, consequently, from the unequal growth of the two limbs, that on which the operation has been performed becomes so disproportioned to the other as to be ultimately useless. The only practical proof of this being so, which I can find, is Mr. Syme's case; and I think it is possible that it might be attributed in this instance to ankylosis not having taken place. Experiments have been performed on animals, to show that bones do not grow when deprived of their heads; but the results do not appear to be conclusive. A few years will be required to confirm this as a valid objection to the operation. Mr. Jones has, in the mean time, made accurate measurements of the limbs of the three boys on whom the operation has been performed, and will have an opportunity of giving further information on the subject hereafter. I have, in an earlier part of this paper, mentioned the fact, that the limb in one of Mr. Jones's cases had already, since the operation, grown considerably, and presented now no appearance of checked growth. As bearing on this question, I would be glad to know if the growth of the upper extremity is checked by excision of the elbow-joint. It is so, as far as I remember to have observed, only in a slight degree. Supposing, however, that the limb is much *respectively* shortened in after years, the objection applies only to the operation being performed on children, and has nothing to do with the question of the propriety of excision in the adult.

"I have suggested that an error has, till lately, been committed in the performance of the operation, which has been allowed to interfere most seriously with its result. I refer to *the removal of the patella*. It is said that the patella is generally extensively diseased in affections of the knee-joint, demanding excision or amputation: this, I have no doubt, is an error. The amount of disease to which it is liable is very limited,—in the great majority of cases consisting only in its being more or less deprived of its cartilage, and of a rough, or perhaps carious condition of its articular aspect. The patella is rarely, if ever, the primary seat of the disease in affections of the knee-joint. The advantage of leaving the patella cannot fail, I think, to be very great. The natural form of the joint is preserved; the attachment of the extensor muscles is left undivided; the wound is less extensive; the annoying tendency to displacement forwards of the end of the femur seems, in a great measure, to be done away with; and there is every reason to believe that the consolidation of the bones will proceed more rapidly, and the limb ultimately be found both more useful and more seemly, than when that bone is taken away. This is a point, however, which remains to be proved. In the last two cases, however, in which the operation has been performed by Mr. Jones and myself, the patella has been left, and the advantages of its having been retained are apparent.

"The semilunar incision seems to me the most advantageous, as being the smallest by which the joint can be satisfactorily exposed, and as giving rise to less bleeding than the H-shaped incision. There is one point, however, to which I wish to direct attention. It has been recommended that a considerable portion of integument should be removed by a double lunated incision, to prevent the redundancy of skin which might be expected from the large amount of bone removed in the operation. I believe that this advice, if followed, will lead to great annoyance. I have not removed any portion of integuments in the cases in which I have performed the operation; notwithstanding which, the retraction of the skin was such as to cause, in each case, more or less gaping of part of the wound. Mr. Fergusson mentioned to me that he had removed a small portion of integuments in the operation, in the case now in King's College Hospital; and that, during the patient's convalescence, he had much reason to regret having done so, as the retraction of the integuments was such as to leave part of the end of the femur uncovered, and a thin cicatrix only now covers this point of bone.

"I shall not add any further details as to the performance of the operation or the after-treatment of the patient. My chief object at present is to present a summary of the cases in which the operation has been recently performed, and the results of these cases as far as they have gone; and I have endeavoured to do this faithfully and impartially. From what I have myself seen, I am satisfied as to the utility of the operation, and I think that the details which I have given of these cases, prove that the operation, till its recent revival, had been banished from surgical practice on insufficient grounds, and that the propriety of practising it in certain cases is still at least an open question."

* Of the last eleven cases in which the operation of excision has been performed, seven have recovered, and two are in progress of convalescence, at the periods of six and three weeks after the operation; two only have died, one from dysentery, and the other from pyæmia.

† Syme, on Excision of Diseased Joints. 1831.

‡ Ibid.

PROVISIONAL CALLUS NOT NECESSARY FOR REPARATION OF FRACTURED BONE.

The doctrine of Dupuytren, that a provisional callus is formed in the reparation of fractures, has been almost universally taught in late years, and is believed by most surgeons to be correct. Yet the observations of Mr. PAGET of St. Bartholomew's Hospital, and Dr. F. H. HAMILTON of Buffalo, U.S., go far to show that this is far from being generally the case.

In his lectures on *Repair and Reproduction after Injuries*, delivered in the Royal College of Surgeons in 1840, Mr. PAGET writes as follows:

"I must express my conviction that the description drawn by Dupuytren and others, from examinations of fractures in dogs, rabbits, birds, and other animals, cannot be applied without great deductions to the case of fractures in the human subject. True as the pictures are of the cases of the animals examined, they are exaggerations of the process in our own case. With a few exceptions, all that is written in these accounts of external and internal provisional and definitive callus, of the formations of cartilage and bone within the medullary tube and beneath the periosteum, can be traced only, as it were, in rudiment in the fractures of the human bones.

"In the ordinary repairs of simple fractures in the human subject, the reparative material, or callus, is merely inlaid between the several fragments; it fills up the interspaces between them and the angles at which one fragment overhangs another; but it does not encircle or ensheath them, in the manner implied in the description of provisional callus; nor is it in any considerable quantity, if at all, deposited either beneath the periosteum or within the medullary tube. In birds, dogs, and other ordinary subjects of experiments, the formation of a provisional, or as it may perhaps be better called, an *ensheathing* callus, is usual: yet even in animals it is not constant. To obtain what would be called good specimens of provisional callus, the injuries must be inflicted upon young animals; and among these I cannot but suspect that particular instances have been selected for description—those in which less callus was formed having been put aside as imperfect instances of repair, though, in truth, they may have displayed the more natural process.

"For fractures in the human subject, the evidence that union is accomplished by the reparative material being placed between, not within and around, the fragments—i.e., as an intermediate, not an ensheathing callus—this evidence may be obtained by the examinations of such fractures even long after they are completely healed. Whether the fragments were in apposition, or nearly so, or wide apart, still there is no appearance of new bone being formed on the outer side of any fragment—I mean on that side which is turned away from the other fragments. And this is the case even in those instances in which there is so much displacement of the fragments, and so much distortion, that we can hardly suppose the repair to have proceeded very quietly. Neither in any of these do we find new bone within the medullary tube. It may be objected by some to these specimens, that the fragments were once ensheathed and blocked up with callus, and that it has been since absorbed. But this is not probable, seeing that in many cases there remain, on the outer surfaces of the fragments, certain marks of their original form and slight irregularities.

"In all the specimens of fracture (with the exceptions presently to be mentioned) that I have been able to examine, in the human subject, within six months of the time of the injury, there has been the same absence of provisional or ensheathing callus. The specimens are—a radius, four weeks after the fracture; another, four or five weeks; a tibia, five weeks; a femur, six weeks; another of the same date; a third, I should think, about eight or nine weeks; a radius, of somewhat later date; a tibia, eight weeks; a fibula, eleven weeks; a tibia, twelve weeks; and a tibia, sixteen weeks after the injury. Here are, also, others of various but unknown dates, all in process of apparently natural repair. All these were cases of simple fractures, and they include (with a few exceptions presently to be mentioned) all the specimens of such recent fractures, in the human subject, as are in the museums of the College and of St. Bartholomew's Hospital. The displacements and other conditions following the injury have been manifestly various: but all agree in this—that the fragments are united by intermediately-placed reparative substance, and that this, whether soft or osseous, in no case surrounds or ensheathes the fragments, or does more than just close in the medullary canal. When present in the large quantity, it is only enough to smooth off the chief irregularities, and to fill up the interspaces and the angles or corners between the fragments.

"If now it be inquired why this difference should exist in the corresponding processes in man and other animals, I believe still that it must be ascribed principally to the two causes already quoted from the catalogue—namely, the quietude in which fractures in our bones are maintained, and the naturally greater tendency to the production of new bone which animals always manifest. Even independently of surgery, in the case of fractures of the lower extremity, the human mode of progression almost compels a patient to take rest; and in fractures of the upper extremity, the circumstances of human life and society permit him to do so far more than other animals can. The whole process of repair is, therefore, more quietly conducted; and, as we may say, there is comparatively little need of the strength which the formation of provisional callus would give a broken limb.

"The exception to the rule of difference in the repair of human bones and those of animals confirm it as thus explained; for the only bones in which, in the human subject, a provisional callus is generally or naturally formed, for the repair of fractures, are the ribs. In cases of fractured ribs one may see, indeed, a very close imitation of that which is described, from experiments on animals, as the ordinary mode of union. The provisional callus is well formed under the periosteum, and encircles, like a broad ring or ferrule, both the fragments, and may almost completely ossify before their union is accomplished, or even apparently begun.

"Another bone for the repair of which, but more rarely, callus is formed around the ligaments, is the clavicle; and the best specimen in which I have here seen it is one in which the fracture was not detected, and the fragments were allowed to move on one another, till the patient died twelve weeks after the injury."

Dr. HAMILTON, in a paper in the *Buffalo Medical Journal* for February 1853, after observing that Liston appears to have noticed the absence of callus soon after the union was completed, and that Mr. Stanley has declared provisional callus not to be uniformly present, says:

"I am now prepared confidently to affirm that the so-called provisional callus never constitutes any part of the reparative process in the union of divided bones, when all those circumstances of simplicity, apposition, quietude, health, just management, etc., obtain, which may properly be considered essential to a normal process—that bones unite most naturally by definitive callus, and that provisional callus is accidental and secondary—the result probably of undue excitement alone.

"Broken bones unite when submitted to the most favourable circumstances, by definitive callus or by a process allied to adhesion—by *first intention*: but under less favourable circumstances by provisional callus, or by a process allied to granulation—by *second intention*.

"Such are the conclusions at which I have arrived, after having examined several hundred fractures, nearly one-half of which were sufficiently recent to have enabled me to discover the callus if any had ever existed.

"There is generally no difficulty in determining the presence of provisional callus in fractures of such superficial bones as the inferior maxilla, clavicle, radius, ulna and tibia, of the metacarpal, metatarsal and phalangeal bones, and, indeed, very often in fractures of other bones. Frequently the swelling is so inconsiderable, that the surface of the bones can be distinctly felt at any period of the process of union. I have seized all such opportunities as were afforded me; and without being able to state numerically the result, I have no remaining doubt that provisional callus is not present in any stage of the reparation where the conditions of health, etc., etc., before stated, exist.

"The accuracy of these conclusions can only be tested by similar examinations upon the dead or living human subject. It is not possible, I think, to put the limb of any brute animal into that condition of rest requisite to determine nature's *first intention*: and here is the source of the fallacy into which Dupuytren and his disciples have been led.

"In the reparation of fractures occurring in certain bones, or in certain parts of bones, provisional callus, it is conceded, seldom or never occurs. Thus it is with the cranium, acromion process, coracoid, olecranon, patella, etc., and with all those portions of bones which are immediately invested with a *synovial capsule*."

Dr. Hamilton concludes with the following recapitulation.

"I. Broken bones unite directly, naturally and by *first intention*, through the interposition of definitive callus.

"II. Broken bones unite indirectly, and accidentally, through the intervention of provisional callus."

"III. The absence of provisional callus does not denote that it could serve no useful purpose.

"IV. Its presence does not indicate its necessity or utility.

"V. It has, therefore, no final purpose, but is the unavoidable result of a certain abnormal condition: and while it is doubtless true that in fractures it frequently renders valuable assistance to the surgeon, it is also equally true that it often proves a source of hindrance."

CYST IN THE THYROID BODY CURED BY INJECTION OF TINCTURE OF IODINE:— ANALYSIS OF FLUID.

In the *Monthly Journal of Medical Science* for June 1853, Dr. DOUGLAS MACLAGAN relates the case of a young lady, who consulted him on account of a pyriform painless swelling in the left half of the thyroid body. It diminished under the external application of tincture of iodine, and the internal use of iodide of potassium; but afterwards returned to its original size. Professor Syme, who saw the case, advised that it should be punctured with a trochar, and injected with tincture of iodine. Two ounces of fluid were drawn off; and about three drachms of tincture of iodine were injected and left in the cyst. The patient suffered little or none, only to a small extent for two days from the inflammatory action excited by the injection, and in a week was able to go about as usual. The tumour entirely disappeared.

The fluid removed was quite clear, in this respect differing from that removed by tapping from other parts of the body. Dr. MacLagan made a careful analysis of it, with the following result:—

Water	989.44
Albumen	1.16
Liquid fat	0.22
Solid fat, with urea (?)	0.34
Soluble animal matter	1.48
Phosphate of lime	0.26
Chloride of sodium	5.80
Chloride of potassium	0.32
Sulphuric acid, lime, magnesia, etc.	0.64
Loss	0.34
Total solids	10.56
	1000.00

This fluid differed from most of those, the analyses of which are recorded, in the absence of colouring matter, and the small amount of solids. The fluid removed from ordinary hydrocele of the *tunica vaginalis* contains from 6 to 17 per cent. of solid matter, of which from 4 to 6 is albumen; while here the total solids were almost exactly 1 per cent., and the albumen little more than 1 per 1000. It is evident, Dr. MacLagan observes, from the variations in size of this tumour from time to time, that absorption and reaccumulation of fluid took place much more readily than is commonly observed in such cases; and this may have been connected with the tenuity of the fluid contained.

CHANCRES SUCCESSFULLY TREATED BY THE LOCAL APPLICATION OF ACETIC ACID.

Some time ago, RICORD stated that, in the course of his experiments upon the inoculation of syphilis, he discovered that acetic acid deprived the pus of a primitive venereal sore of its power of being inoculated. M. HENROTAY drew from this a practical suggestion for the treatment of chancres. He concluded that, if Ricord's observations were correct, the local application of acetic acid might be found to be the very best treatment of a chancre. His trials were crowned with success, and several French and Belgian surgeons (among whom may be mentioned Dechange and Gouze) have confirmed the accuracy of his reports, and recommended acetic acid as an excellent application for healing troublesome venereal sores, and especially as a much better caustic than nitrate of silver for the abortive treatment of chancres. The cases treated are apparently so satisfactory as to warrant us in recommending a trial of this method of treating venereal sores.

MAGNESIA A CURE OF WARTS.

Topical applications in great variety are used for the purpose of removing warts, and many of them often prove successful. Among those which are used with most advantage, and with the least inconvenience, are strong acetic acid, and the recent milky juice of the *euphorbia lathyris*, an indigenous plant, to be found in great abundance at the sides of hedges, and as an inveterate weed in many gardens. When warty growths are luxuriant in

the genital organs, or on other parts of the body, it is often proper to commence the treatment by freely removing them by the knife or nitric acid.

As a constitutional remedy for warts, several authors (commencing with Dr. Eckstein, of Pesth, in 1841) testify in favour of magnesia. The following case is related by Dr. Peez, of Wiesbaden. A man, of cachectic appearance, had taken, for the cure of gastric acidity, a tablespoonful of magnesia night and morning. The symptom for which the medicine was ordered was not alleviated, but a growth of warts, which almost entirely covered his hand, disappeared. This occurrence has led Dr. Peez to prescribe magnesia in many cases of warts; and he reports very favourably of the results.

TOXICOLOGY.

THE STATE POISON OF THE ATHENIANS, USED IN THE CASE OF SOCRATES.

In the *Dublin Quarterly Journal of Medical Science* for May 1853, Dr. JONATHAN OSBORNE enters on an examination, from the evidence afforded by ancient writings, of the nature of the state poison employed by the Athenians, and which was used in the case of Socrates.

The author first gives an interesting historical review of the knowledge of poisons which the ancients possessed, and which is shewn to have been very scanty.

The most complete evidence of the limited toxicology of the ancients is to be found in the work of Dioscorides, written in the reign of Nero. The following were all the vegetable poisons known to him:—Colchicum (*Εφάμερον*): Dorycnion, not identified: Aconite, and the honey of Heraclea in Pontus, where that plant abounded: Coriander (*Κόριον*), identified with our *coriandrum sativum*, but stated to cause a temporary insanity, like that of drunkenness, irreconcilable with any modern observations: Psyllium, identified by Sprengel with the *plantago psyllium*: Conium: The yew (*Σύλαξ*), well identified, and described as fatal to cattle: The juice of carpasus (*Καρπασου ὄνυς*), causing stupor and suffocation; entirely unknown: Sardonian (*Σαρδονία πύα*) a kind of ranunculus, from Sardinia, causing spasmodic motions of the lips (whence the term *risus Sardonicus*), and also affecting the intellect: Hyoscyamus: Mandragora, nearly identified with *atropa belladonna*: Meconium, evidently opium, and described as the juice of the poppy: Phacium: Toxicum, used by barbarians for poisoning arrows; if swallowed, causing inflammation of the lips, with furious madness, requiring the patient to be tied: Fungi, either taken in excess, or from some peculiar kinds intermixed, causing strangulation: White hellebore: Thapsia; doubtful whether *Thapsia gargarica*, or *asclepium*, described as emetic and cathartic.

Dr. Osborne then quotes the account of the death of Socrates, as given in the *Phædon* of Plato.

"When the fatal cup was brought, he asked what it was necessary for him to do. 'Nothing more,' replied the servant of the judges, than 'as soon as you have drank off the draught, to walk about till you find your legs become weary, and afterwards lie down upon your bed.' He took the cup without any emotion or change in his countenance, and looking at him in a steady and assured manner, 'Well,' said he, 'what say you of this drink? May a libation be made out of it?' Upon being told that there was only enough for one dose, 'At least,' said he, 'we may pray to the gods, as is our duty, and implore them to make our exit from this world and our last stage happy, which is what I most ardently beg of them.' Having spoken these words, he kept silence for some time, and then drank off the whole draught. After reproving his friends for indulging in loud lamentations, we are informed that he continued to walk about, as he had been directed, till he found his legs grow weary. Then he lay down upon his back, and the person who administered the poison went up to him, and examined for a little time his feet and legs, and then, squeezing his foot strongly, asked whether he felt him? Socrates replied that he did not. He then did the same to his legs, and proceeding upwards in this way, showed us (Plato is speaking) that he was cold and stiff; and he afterwards approached him, and said to us, that when the effect of the poison reached the heart, Socrates would depart. And now the lower parts of his body were cold, when he uncovered himself, and said, which were his last words, 'Crito, we owe Æsculapius a cock. Pay the debt, and do not forget it.' 'It shall be done,' replied Crito, 'but consider whether you have anything else to say.' Socrates answered in the negative, but was in a short time convulsed. The man then uncovered him; his eyes were fixed; and when Crito observed this, he closed his eyelids and his mouth."

Dr. Osborne thinks that it may be proved that hemlock was the poison used: by examining, first, the name used; secondly, the botanical characters and collateral details; and thirdly, the series of symptoms.

The φάρμακον of Plato is called κόνιον by Xenophon, in his account of the execution of Theramenes, between whose death and that of Socrates only forty years intervened. In the *Frogs* of Aristophanes, also, we find κόνιον mentioned by name. The Latin authors, especially Pliny, always use the word *cicuta*, in mentioning the poison employed at Athens; and, in the modern Greek Pharmacopœia, the name given to hemlock is κόνιον πύλα.

The botanical characters of κόνιον, as given by Dioscorides and Pliny, are such as to lead to its identification with hemlock. According to Dr. Sibthorpe, the *conium maculatum* is very common in Greece, and no other poisonous umbelliferous plant is to be found in that country. Pliny describes the seeds of *cicuta* as the most noxious part; and Professor Geiger, of Heidelberg, has found the conia in the seeds to exceed that of the rest of the plant in the proportion of 133 to 1.

The symptoms in the poisoning of Socrates are viewed by Professor Christison as irreconcilable with those produced by any poison now known. Dr. Osborne, however, makes out a good case in favour of the contrary opinion.

"In the first place, when the executioner informed him that his legs should be the first to become paralysed, he must have done so from the observation of its effects on former occasions; and, to show that hemlock does first paralyse the lower extremities, I cannot do better than quote from the truly valuable series of experiments made by Dr. Christison himself. In the first of these, six drops of conia were dropped into the throat of a puppy ten weeks old. In thirty seconds, there was sudden convulsive respiration, stiffness of the hind legs, immediately followed by great feebleness of these limbs. In a few seconds, the fore legs also became very feeble. In sixty seconds after the introduction of the poison, the breathing ceased, and slight convulsive tremors followed for a single moment more. In the second and third experiments with puppies, the hind legs were first affected. In the last, after all its limbs became completely paralysed, yet, when called to, it wagged its tail feebly, turned its head in the direction of the voice, and made a feeble effort to raise the head, but could not; its movements did not completely cease till forty-two minutes.

"In the fifth experiment, on a rabbit, the hind legs became stiff in one minute and a half, and the fore legs not till two minutes and a half. In the ninth experiment, three drops of conia were dropped into the eye of a strong and furious cat. Instantly it made violent efforts with its fore legs to rub out the poison; while continuing so to do, the hind legs in forty seconds became affected with slight convulsions, and then grew so weak, that it could not support himself on them. Soon after, the fore legs also became weaker and weaker; all voluntary motions, however, did not cease until ninety seconds had elapsed.

"In the fifteenth experiment, when a solution of the extract of hemlock was injected under the skin of a dog's back, in three minutes and a half the hind legs were weak and rather stiff, and in six minutes the fore legs also, and in twenty minutes the respiration ceased. In all, the paralysis commenced in the hind legs; and in no one instance of the sixteen experiments related in Dr. Christison's paper did the symptoms occur in an inverse order. It is also to be noted, that in all, the eyes of the animals under the poison remained open. This was also the case at the death of Socrates; for, in the relation of Plato above quoted, it is stated that, when his body was uncovered, his eyes and mouth were closed by Crito."

The coldness of the limbs was a well known effect of the state poison; and it seems to be alluded to in the *Frogs* of Aristophanes:—

"*Hercules*. Then there is a short and beaten road—by the mortar.

"*Bacchus*. Speakest thou of hemlock, then?

"*Hercules*. Most certainly.

"*Bacchus*. A journey cold and winterly, forsooth; for it immediately congeals the shins.*"

* HP. ἀλλ' ἔστιν ἀτραπὸς ξυρταπὸς τετριμμένη
ἢ διὰ βύβας.

HP. μάλιστα γα.

ΔΙ. ψυχρὸν γα καὶ δυσχεμεραν,
δυσὲς γὰρ ἀποτήγγουσι τ' αὐτοκρήμια.

It was also mentioned by Nicander (ἄσπερ δὲ τοὶ φέρεται); and also by Dioscorides and Pliny; and has been referred to in three modern cases, one related by Orfila (*Traité des Poisons*), the second in the *Journal de Chimie Médicale* for August 1842, and the third by Dr. Hughes Bennett, in the *Edinburgh Medical and Surgical Journal*, 1845. We quote the latter case:—

"Duncan Gow, a tailor, forty-three years of age, was brought in the evening by the police into the Royal Infirmary, Edinburgh, apparently in a state of intoxication, but on being taken into the waiting-room was found to be dead.

"Dr. Bennett, who made an examination of the body, recognised a quantity of vegetable matter in the stomach to be the leaflets of the *conium maculatum*. He also identified it by the odour exhaled, when beaten up with a solution of potash, and by an inspection of the plant growing in the locality where it had been gathered.

"The unfortunate man was in extreme poverty, and on this day had taken nothing except a share (along with two others) of half a mutchkin of whisky. The hemlock having been brought to him by his children, in mistake for parsley, he greedily ate it along with bread. Death must have taken place within about three hours and a quarter afterwards. Dr. Bennett was able to collect the following particulars from policemen and others, who saw him within this interval of time.

"He was observed to stagger as he went down some steps. To some children who were sitting on the steps, he said, 'get out of the way of the lame horse.' One witness described that he could not walk rightly, and was staggering as a man in liquor. His mode of progression attracted a number of boys and girls, who laughed at him, believing him to be intoxicated. He was heard to speak to them, but what he said is not known. In reply to a policeman, he desired to be taken to his own house at the top of the Canongate. He also said that he had completely lost his sight, and had not the perfect use of his limbs, but expressed his willingness to walk forwards till assistance could be procured. Although supported by one arm, after moving with great difficulty past four or five shops, his legs bent under him, and he fell upon his knees, and when he was pulled on by the police, his legs were trailed after him. One of the police-officers, on first seeing him, pronounced that he was not drunk, and another confirmed it from the manner in which he was lying, and from the loss of power in the legs. Dr. Tait saw him in about two hours. He found his powers of motion completely prostrated; his pulse and breathing perfectly natural. He thought he perceived the odour of spirits about him, but the policeman thought otherwise. The heat of skin was natural. In forty minutes afterwards, all motion of the chest appeared to have ceased; the action of the heart was very feeble; and the countenance had a cadaveric expression; pupils fixed. In this state he was brought to the Infirmary, and on his arrival was found to be dead. As Dr. Bennett observes, perfect paralysis of the inferior extremities was ascertained one hour and a half after the poison was taken, and that of the arms half an hour later.

"The temperature remaining natural, has not been mentioned whether in the body or extremities; and from Dr. Tait being at first under the impression that it was a case of intoxication, it probably may not have occurred to him to examine this point closely. Besides, as fourpence was missing from his pocket, he may have taken whisky, with the effect of keeping up heat longer than usual."

Dr. Osborne next proceeds to examine into the action of hemlock on the mind, as shewn by the direction given by Socrates "to sacrifice a cock to Esculapius". He believes these words to have been spoken by Socrates while under the influence of a narcotic poison rendering him delirious; and that attentive consideration will add this to the proofs that the poison used was hemlock.

Nicander of Colophon, in his Ἀλεξίφάρμακα, describes hemlock as abolishing the mental powers; and Dioscorides mentions disturbance of the mind as one of the symptoms. Slight delirium and hallucinations are also mentioned by other authors. Furious delirium, stated by many writers on *Materia Medica* to be a symptom of poisoning by hemlock, is believed by Dr. Osborne to be unproved by any credible evidence. In his own experience, he has found that "with the extract, and more especially with the tincture of the seeds of hemlock, when perfect and profound sleep has not been obtained, dreams of a peculiar character have been substituted. In these the hallucination was rather agreeable than otherwise, generally recalling the ordinary occupation of the individual; but yet always accompanied by a sense of some impediment, or of some difficulty arising from a want of bodily power. For example, a

horse-clipper recovering from acute rheumatism, after two grains of the extract, was exhilarated at finding himself working at his professional employment, and the only drawback was great stiffness and weariness in handling the scissors. A young woman, from twenty-five drops of tincture of the seeds, dreamt of her native village, and had all the surrounding scenery full in view, but was obliged to cross a river, and was in great terror from the difficulty of avoiding falling in. The dreams suggested by it are in imaginative range quite inferior to those of opium, and appear to be just of that extent that, when Socrates felt his limbs becoming powerless, he was likely to think of bodily infirmity, and then of medicine, and, by association of ideas, of *Æsculapius* and the cock, the bird usually sacrificed to that divinity."

Dr. Osborne has found that fresh hemlock juice has a cathartic effect, "from which the extract is comparatively free. Hence, if given in this form as a poison, it must have been liable to failure, and could not have been relied on. It would appear then absolutely necessary to combine it with some ingredient to correct this tendency. Nothing was so well suited for this purpose as the juice of the poppy, which was well known, and was also an indigenous plant in Greece. In the course of my trials with hemlock, I was induced to combine it with opium, giving them in half doses conjoined, as an equivalent for one entire dose of either. In this way, not only was the cathartic effect of the hemlock prevented, but a deeper and more certain hypnotic effect was obtained. When the sleep was accompanied by dreams, the latter partook more of the hemlock than the opiate character. Thus one dreamed of his brother, whom he had not seen for two years. In another dream, he was near his home in the country, but was pursued by some kind of nondescript animal, from which he was endeavouring to escape, but ineffectually, on account of a numbness in his limbs. Another went to the fair to sell a cow, but was in great perplexity on account of a cow having strayed away from him. On another occasion he was near his residence, but could not get to it from a want of power in his limbs.

"Now it is proved that some such combination was known at the time, from the following passages in Theophrastus,* who was born only twenty-eight years after the death of Socrates. These are his words:—Thrasylas, the Mantinean, stated that, by making use of the juices of the *σκόπιον*, the poppy, and such other things, he had discovered a substance which occasioned death easily and without pain, and so portable and minute that the weight of a *δραχμή* was sufficient and absolutely irremediable, and it was capable of being preserved for any time without alteration."

The author sums up in the following words:—

"I think it is nearly proved that the *φάρμακον* mentioned by Plato was essentially hemlock, and that there is also a strong probability that it was mixed with poppy juice; that during the operation of the poison, and after the numbness of the legs, it occasioned a slight delirium, under the influence of which the last words of Socrates were pronounced; that these words are to be set apart from the discourse previously delivered by him, and to be considered as the result of a narcotic poison."

FATAL INTESTINAL HÆMORRHAGE PRODUCED BY TARTAR-EMETIC.

The following case is related in the *Gazette des Hôpitaux* for March 26th.

In the early part of February, there was admitted into la Charité, under M. Piorry, a woman, aged 56 years. She was extremely weak; a condition which might be due to the insufficiency and bad quality of her food before her admission.

She was found to be suffering from broncho-pneumonia. As she stated that bleeding had always relieved her in former similar attacks, five hundred *grammes* (3*xxvi*) of blood were taken, without the least improvement. Fifteen *centigrammes* (gr. *iiss*) of tartar emetic were then ordered to be given in a single dose.

On the following night, and without any premonitory symptom being afforded by the digestive organs, profuse intestinal hemorrhage suddenly occurred. More than four pints of black, thick, pitchy blood were discharged *per anum*. There was extreme prostration. The heart and liver were greatly diminished in volume; the veins were empty; the pulse was frequent and very small; the lips were deadly pale. At the same time, the lungs became more elastic and sonorous, notwithstanding the persistence of the rhonchi.

M. Piorry found by pleximetry that the descending colon and

sigmoid flexure were full of fluid; and the blood which he could cause to flow from the anus by dilating the sphincter, and which could be felt in the rectum, pointed out that the fluid in the rest of the intestines was of the same nature. The absence of antecedent circumstances, such as hemorrhoidal tumours, diarrhoea, etc., led him to conclude that there was hæmorrhage from the large intestine, due to a diminution of fibrin in the blood, as occurs in scurvy; and that the hæmorrhage had occurred by exhalation.

Ice was placed and retained on the abdomen; water at 32 deg. Fahr. was injected into the rectum; extract of rhatany and pills of alum and dragon's blood were given; but the hæmorrhage continued, accompanied with dulness in the lower part of the large intestine. The pulmonary rhonchi increased and became general.

On February 26th, the patient died.

A *post mortem* examination was performed on Feb. 28th. The stomach and small intestines were healthy. Two brownish red oval spots, two *centimètres* in diameter, were present in the duodenum. The descending colon, and especially the rectum, presented an appearance similar to that of these spots, but without ulceration: their whole mucous surface was covered with dark viscous blood. There were no hæmorrhoids at the anus, nor any organic lesion in the rectum. There were slight traces of engorgement in the lungs. The trachea and bronchi were filled with sanguinolent froth.

DANGER ARISING FROM THE USE OF COPPER CHIMNEYS TO GAS-LAMPS.

The *Gazette des Hôpitaux* for May 14th quotes the following from the *Journal de Chimie Medicale*.

Persons who employ gas to light their shops or dwellings, and who use an apparatus surmounted by a copper chimney, must have observed on the chimney a white powder like flour. An examination of this powder has shown that it consists of anhydrous sulphate of copper—the same substance which is known in commerce as blue vitriol, its colour being due to the water of crystallization which it contains. Its formation is easily explained. Badly purified gas contains a certain quantity of hydrosulphuric acid: this, under the influence of heat, is transformed into sulphuric acid, and thus sulphate of copper is produced.

That the white substance referred to is sulphate of copper, may be proved by dissolving some in water, when a light azure tint is produced; on adding ammonia in slight excess, a splendid deep blue results. The precipitate formed by adding baryta water proves that it contains sulphuric acid.

The extreme fineness of the dust renders it more dangerous, as the least draught of air or shake may disperse it into the air. Hence arise *malaise* and the pain on the stomach, which are often ascribed to other causes.

It would be wise to substitute chimneys made of glass or porcelain in place of those of copper.

TENIA AND ITS REMEDIES. BY EDWARDS CRISP, M.D.

Dr. CRISP stated, that kouso appears always to expel the *tænia en masse*, while turpentine and the male fern break it. Out of seventeen cases which he had seen in the last three and a half years, six had been cured by turpentine, one by kouso, and one by the oil of male fern. He therefore concluded, that kouso and the fern oil are not more efficacious in the cure of *tænia* than is oil of turpentine.

Dr. HARE observed, that it is often very difficult to ascertain whether the head of the worm has or has not been evacuated. He thought that kouso had some advantage over turpentine.

The PRESIDENT, in reference to an observation made with regard to the frequency of cerebral disturbance in cases of *tænia*, said that insanity has been cured by the removal of this parasite.

Dr. DAVEY related the case of a boy, aged 14, in whom symptoms of acute mania appeared: calomel, turpentine, and castor-oil, were given, and a quantity of *tænia* evacuated. He recovered in two or three days.

PHYSIOLOGICAL USES OF THE GANGLIONIC NERVOUS SYSTEM. BY
JAMES G. DAVEY, M.D.

Dr. DAVEY's principal object was to prove the independency of the organic nervous system, and the dependency on it of the integrity of the cerebro-spinal system, in common with all the organism. Dr. Davey affirmed, that the ganglia of the sympathetic nerve are the parts first formed in the fetus; and that the same fact probably obtains equally through the whole animal kingdom. Reference was made to two monstrosities recorded by Mr. Lawrence and Dr. Marshall Hall. The first of these was born without a brain, but with the spinal cord complete; but the second was amyelencephalous. Dr. Davey argued, that if, in the latter instance, the vital functions were duly executed without aid from a cerebro-spinal system, then was the latter in no instance necessary to their integrity. The ganglionic nervous system, according to Dr. Davey, is perfect at birth, and its functions are perfect; whilst the brain is a mere pulpy mass, without function or use. Dr. Davey compared the monstrosity of Dr. M. Hall to the lower classes of animal life, as the *medusariae*. The nervous organism of the amyelencephalous monster and the zoophyte was precisely similar; and their animal functions were on a par. Dr. Davey cited some examples of vivisections performed by himself. In frogs and fish, both the brain and spinal cord may be destroyed; and nevertheless all the strictly vital functions will continue to be carried on as before. The phenomena of sleep and disease were referred to, as offering strong and corroborative evidence of the physiological opinions insisted on. Lunatic asylums afford many instances of individuals reduced to a state of mere vegetation or organic existence, by disorder of the brain and spinal cord, but who often live many years, without passion or sensation, and capable of only the most imperfect motion: they nevertheless carry on the strictly vital functions. Dr. Davey referred to the experiments of Sir B. Brodie, to prove that the nerves of cerebro-spinal origin had no influence on the reparation of injuries. He explains the facts recorded by Sir B. Brodie by saying, that the ganglionic nervous power was left intact; and that this caused the wounds to heal and the fractures to unite. The author then referred to the effects of blows and injuries to the solar ganglion and its dependencies. This ganglion he asserted to be the seat of life, the *locale of the impetus faciens* of old writers; the irritability, the motions without force, of Haller. Instinct and animal heat were also treated of as specific functions of the sympathetic nervous system.

NEW METHOD OF APPLYING THE TOURNIQUET IN AMPUTATION OF
THE THIGH. BY HAYNES WALTON, ESQ.

Mr. WALTON introduced a new plan of applying the tourniquet in amputations of the thigh, by which the pad is made to press on the artery just as it is passing over the pelvic bone. The application is effected by carrying the strap over the thigh and the pelvis, in the form of the figure 8. The advantages advanced were, the tourniquet being out of the way of the operator in amputating high; the readiness with which the vessel can be found and compressed in fat or very muscular subjects; and the ready application of the instrument, and its great stability. The only alterations from the common tourniquet which are required are a longer strap and a conical pad.

ANÆSTHETIC PROPERTIES OF THE LYCOPERDON PROTEUS, OR
COMMON PUFF-BALL. BY B. W. RICHARDSON, ESQ.

(This paper is published as an original communication, at p. 479 of last number.)

Dr. SNOW had seen some of Mr. Richardson's experiments, and could confirm his statements. He believed that this was only one of many substances capable of producing anesthesia; and that it might in certain cases be useful; but that it was not likely to supersede the use of chloroform or ether.

PELVIC ABSCESS. BY TYLER SMITH, M.D.

Four cases of pelvic abscess had come under Dr. TYLER SMITH's care in St. Mary's Hospital, within the period of six months.

CASE I. S. B., aged 35, the mother of ten children, was admitted on February 25, 1852. All her labours had been natural except the ninth. She was last confined on January 20. Four days after delivery, the lochia suddenly ceased; and pain soon appeared in the lower part of the abdomen. A month after delivery, she had irritative fever, with suppuration. On

the left side, in the iliac region, and extending into the pelvis, there was a large firm tumour. Under treatment, she recovered somewhat, and was discharged by her own request on March 21.

On April 25, she was again admitted. In two or three days after her discharge, she had had severe pains, obliging her to keep her bed; and in about a fortnight there was a discharge of pus *per vaginam*. No opening, however, could be detected on examination. Soon after re-admission, she complained of pain in the groin; and an abscess burst there, discharging a quantity of dirty pus. During her absence from hospital, her diet had been good. When admitted, she was suckling her infant; but was directed to wean it. She had pain over the left anterior superior spine of the ilium, and a hard mass extended towards the pelvis. When the last was made, the pelvic tumour was much diminished in size, and could not be felt *per vaginam*.

CASE II. C. B., aged 25, was admitted March 18, 1853. Her second labour occurred four months previously. Three days after delivery, the lochia became suppressed; and five days afterwards, she had pain in the abdomen, and a tumour was found in the right iliac region. It was supposed by her medical attendant to be ovarian or fibrous; and leeches and blisters were applied. She had several attacks of inflammation, with discharge from the vagina.

On admission, she was greatly reduced; her pulse was above 100; she had profuse night-sweats. A large swelling was felt above the pubis, extending obliquely upwards, and to the right side: *per vaginam* it could be felt to the right of the uterus. There was some irritability of the bladder. She was discharged, without much change, on April 12. Dr. Smith had heard that she had since been admitted into University College Hospital, and that suppuration had taken place externally.

CASE III. E. R., aged 26, had been confined three weeks before admission. Ten days after confinement, severe pain appeared in the right iliac region. The lochia continued to flow up to the day of admission: the milk had disappeared three days previously.

When admitted, she was much debilitated and exhausted; her tongue was clean and red; her countenance pale and anxious. There was tenderness in the right iliac region, but no tumour could be felt there. On examination *per vaginam*, the os uteri felt small and contracted, and there was apparently a solid mass between it and the side of the pelvis. She was subsequently attacked with rigors, and had a copious purulent discharge from the vagina, with clots of blood. No opening in the vagina could be detected with the speculum. She improved under treatment.

This woman had contracted secondary syphilis from her husband. The child showed symptoms of the disease a fortnight after birth, and died when six weeks old.

CASE IV. J. A., the mother of four children, appeared to have suffered in a previous pregnancy from pelvic abscess, which was evacuated through the rectum. In her last pregnancy, she had had several abscesses in the back.

She was admitted on October 4, 1852, being four months advanced in pregnancy. She had been attacked on 24th September with pain in the iliac and hypogastric regions, which had increased up to the time of admission. The pain extended down the right thigh. Two days before admission, she had severe rigors; but no fluctuation could be detected on examination. Early on the morning of October 6, she had a sudden abortion; she lost very little blood. Vomiting and diarrhoea set in, and continued some time. On October 21, there appeared to be indications of pus in the right iliac region. A small puncture was made, and about two pints of offensive pus were discharged. She soon rallied from her depressed condition: the pus continued to be discharged for some days; and the external iliac artery could be observed pulsating at the bottom of the abscess. On November 2, perforation of the bowel occurred, but was not attended with any unfavourable symptoms. On November 5, the vomiting and diarrhoea returned; and on the 10th she seemed moribund. After this, however, she rallied, and continued to progress favourably until Dec. 16, on which day she was suddenly informed of the illness of her husband, and of other domestic misfortunes. After this she got worse, and died on December 27.

Post-mortem Examination. There was very little inflammatory deposit on the peritoneum. At the head of the cecum, there were firm adhesions, and an opening into the cavity of the abscess. There was extensive burrowing of pus beneath the ascending and the descending colon.

Dr. Smith believed that the disease which he had described was allied to puerperal fever and phlegmasia dolens; and that, in all probability, the earlier changes are identical in all cases.

The parts involved in the disease are the cellular tissue of the pelvis, the lymphatic glands, and the ovaries. He had seen a case connected with procedentia uteri; and also one which was evidently connected with the ovary, as shown by the mobility of the tumour.

The treatment should consist in moderating local inflammation, and keeping up the strength by good food, quinine, etc. He hinted at the possibility of making an opening *per vaginam*, for the evacuation of the matter.

[This was the last meeting of the Society for the session.]

NEWS AND TOPICS OF THE DAY.

VACCINATION EXTENSION BILL:—PETITION FROM THE HUDDERSFIELD MEDICO-ETHICAL SOCIETY.

The following petition has been sent for presentation to the House of Commons by Lord Goderich, from the Medico-Ethical Society of Huddersfield:—

To the Honourable the Commons of the United Kingdom of Great Britain and Ireland in Parliament assembled.

The petition of the undersigned members of the medical profession in the town of Huddersfield and its vicinity,

Humbly sheweth,—

That while they regard the Vaccination Extension Bill now before your Honourable House as intended for the benefit and protection of the nation from small-pox, they nevertheless are convinced that many of the provisions of that bill are defective, and some bear unjustly upon the members of the medical profession.

That while the bill enforces vaccination within a certain age, and renders the parents and guardians of the child responsible for its omission, it does not enforce the obligation to return with the child on the eighth day, for inspection, and to supply the medical practitioner with fresh lymph.

That the onus of transmitting a duplicate of the said certificate of vaccination to the Registrar of Births and Deaths, would, to say the least, be unreasonable, seeing that the medical practitioner is shut out from all remuneration.

In conclusion, your petitioners further suggest, that with regard to the poor, the parents be permitted to apply to their usual medical attendant, who shall be remunerated for every successful case of vaccination by a uniform scale throughout the kingdom; and they think the public confidence would thus be better secured, and the full benefits of vaccination obtained.

Your petitioners therefore humbly pray your Honourable House to make such alterations and amendments in the Vaccination Bill as in your judgment you may deem desirable.

And your petitioners will ever pray, etc.

WILLIAM TURNBULL, M.D., *President of the Medico-Ethical Soc.*
GEORGE ROBINSON, Esq., *Vice-President.*

G. W. RHODES, Esq., } *Honorary Secretaries.*

KING'S COLLEGE HOSPITAL. The quarterly court of the governors and subscribers was held on the 27th ult. From the report it appeared that the total number of patients in the house on the 1st of January last was 110; admitted during the quarter ending Lady Day, 280; total, 390. Received by letters of recommendation, 77; urgent cases without letters, 180; accidents, 23; total, 280. Of this number 159 were males, and 121 females. The out-patients attended to during the quarter were 4,326; and 164 women were attended to during their confinements.

ST. MARK'S HOSPITAL. The anniversary festival of this institution took place on Monday, under the presidency of the Lord Mayor. The list of subscriptions announced amounted to upwards of £800.

NAVAL COURT-MARTIAL ON DR. J. F. HENRY. A court-martial assembled, the 25th ult., on board the *Impregnable*, guard-ship, at Portsmouth, for the trial of James Falls Henry, M.D. (1851), surgeon of her Majesty's brig *Star*, Commander Warren, on a charge of drunkenness. Evidence was given in support of the charge. The prisoner then read his defence. In this document the prisoner stated, that on the occasion mentioned in the charge he had not taken such a quantity of liquor as would have excited an ordinary individual; that he had served twelve years in the service, with credit to himself and satisfaction to his commanding officers, as would be proved by certificates that would be read to the court; that from serving in tropical climates his health had been greatly impaired, at China most seriously; and in the *Helena* on the coast of Africa, when they had as many as fifty sick, he had never shrunk from his duty, and through that had contracted the fever, which, joined to a nervous temperament, had unfortunately caused him to be so excitable that it was his intention, if this prosecution had not intervened, to have applied for a medical survey, believing himself to be unfit to serve again in a tropical climate. No evidence had been brought to stigmatise him as a confirmed drunkard, nor that he was drunk on the day mentioned in the charge, but that he was in a state of excitement. He called Mr. David Webley Perry, midshipman of the *Star*, who said that when he was sent to call the prisoner he awoke immediately on his calling him, and went on deck directly. He appeared to him to be perfectly sober.—Robert Thomas Mason, clerk of the *Star*, and Mr. Richard Blizard Power, assistant-surgeon on board the *Sanapareil*, who had previously sailed with the prisoner, both spoke to his excitable state of health, the latter having seen him at different times in a state of excitement, when he was perfectly convinced he was not drunk.—Most satisfactory testimonials were read of the prisoner's general good conduct and professional capability, from Captain Richards, of the *Corwallis*; Captain Goldsmith, of the *Wellesley*, in China; and Commander Ricketts, of the *Helena*, on the coast of Africa; with all whom he had served.—The Court considered that the charge had been proved, and sentenced him to be dismissed the service.

EXTRAORDINARY CASE OF LOVE-SICKNESS. BROMPTON COUNTY COURT. This action, brought to recover the trifling sum of 15s., elicited facts as interesting to young ladies as to the medical profession. The plaintiff, Mr. Gay, is a surgeon, and the defendant, Mr. Paine, is an unmarried gentleman. Mr. Gay said he had supplied the defendant with a mixture and a box of pills, and had attended him six times, for which visits he charged half-a-crown each. He had not charged for the mixture. Mr. Delamere, the defendant's solicitor, said that his client resided with a gentleman at Brompton, who had a family of beautiful daughters. Mr. Gay, who was a single man, was anxious to obtain an introduction to the young ladies, with the view to choose a wife. With this object he sought the services of Mr. Paine, who, very foolishly, pretended to be ill, and accordingly the professional services of Mr. Gay were sought to alleviate the sufferings of the patient. Mr. Paine, on being called, stated that Mr. Gay informed him of his wish to pay his attentions to a nice young lady, as he was sick of being single, and he intreated witness to introduce him to one. He recommended the young ladies at his house; but how to get an introduction was, for some time, a poser. It could only be carried out by a stratagem; and it was devised by plaintiff and himself that he (defendant) should fall ill, and write a letter to Mr. Gay to visit him. He felt unwell, and wrote the note proposed by Mr. Gay.—"Dear Sir,—I want to see you immediately. I am alarmingly ill. Yours, etc.—Postscript. Only myself and the Misses — at home, my boy." Mr. Gay came immediately. There was nothing whatever the matter with him, and he never took the stuff that was sent, but threw it to the dogs. As to the six visits the plaintiff had charged him for, it was a downright do. At any rate, five out of the six visits were paid to the young ladies, and Mr. Gay had the impudence to charge him half-a-crown for each of the wooing visits. Besides that, he was invited to dinner each time. He never had any rash, saving the rashness of introducing the plaintiff to his friends.—The Judge (Adolphus): I think, if it be a joke, it ought to be followed out. Fifteen shillings is, perhaps, too much to pay for it. My judgment will be for ten shillings, and that is not too much for a rich joke.

MEDICAL REFORM.

[House of Commons, June 8rd.]

Lord D. STUART wished to put certain questions to the noble lord the Home Secretary, viz., Whether it was the intention of the Government to introduce a Bill during this Session of Parliament for the better regulation of the laws relating to the profession of Physic and Surgery? Whether it was the intention of Her Majesty's Government to introduce a Bill empowering Her Majesty to grant a New Charter of Incorporation to the Royal College of Physicians of London? Whether, in conformity with the Pharmacy Act, there had been submitted for approval to the Home Secretary, bye-laws for the regulation of the Pharmaceutical Society of Great Britain, and whether those bye-laws had been approved of? Whether there had been forwarded to the Home Secretary the opinion of counsel, declaring those bye-laws to be illegal and unjust, and contrary to the spirit and intention of the Pharmacy Act of the last Parliament?

Lord PALMERSTON replied, that with regard to the first question, undoubtedly the present condition of the medical profession in this country was one that required arrangement, for it was a fearful labyrinth and chaos, owing in a great measure to the many different sources from which licenses and degrees were derived. At the same time, the question was so complicated and difficult, that he could not undertake to propose any measure this year. As to the Charter of the College of Physicians, he hoped to be able to bring in a Bill on that subject during the present Session; but at present he was not prepared to say whether it would be better to grant a separate Charter to the College or to incorporate the Charter in the Bill. He had had a new code of bye-laws in reference to the Pharmaceutical Society under consideration, but had not been as yet enabled to decide whether they were in all respects adapted for their purpose or not. Some parties objected to them, and had forwarded to him a legal opinion against them; but that opinion, it must be remembered, was founded upon the case drawn up by the objectors, and must consequently be taken with allowances. It would be his duty to ascertain from impartial authorities, whether those bye-laws proposed were or were not well founded.

OXFORD HONOURS. Yesterday the University of Oxford conferred the honorary degree of D.C.L. upon four members of our profession, viz., Dr. Bright, Dr. Winalow, Mr. J. H. Green, and Mr. Brande. A number of literary and political persons of more or less celebrity received a similar mark of distinction upon this occasion.

ALTERED MODE OF ASSESSING THE INCOME-TAX. The following important modification of the mode of assessing the Income-Tax has been carried on the motion of the Chancellor of the Exchequer. The duty on professional incomes is to be charged on an average of the profits of three years, instead of on the amount of the profits within the preceding year.

ROYAL COLLEGE OF SURGEONS:—PASS LIST. MEMBERS admitted at the meeting of the Court of Examiners on the 27th of May:—John Henry Aldridge, Christchurch, Hants; Arden Hulme Beaman, King Street, Covent Garden; James Oughton Bradbury, Manchester; Samuel Cardozo, Redruth, Cornwall; Francis Lewis Fitzgerald, Cheltenham; H. George Hardy, North Shields; George Henry Hope, Seaforth, Lancashire; Napoleon Kennett, Shoreditch; Michael Mackereth, Guisborough, Yorkshire; Alfred Malpas Tippetts, Islington; John Harrison Walker, Australia; Hutchins Williams, India.

[At the same meeting of the court, Mr. Dugald M'Ewan, a Member of the Edinburgh College, passed his examination for Naval Surgeon.]

May 30th:—Charles Robert Croft, Wimbledon, Surrey; Thos. Gillham Hewlett, Hon. East India Company's Service; William Hoar, Portsmouth; Henry Rooke Ley, London; James Rawlings Monday, Olverton, Gloucestershire; John Jones Petters, Anglesey, Wales; Frederick John Thomas, Park Terrace, Islington; Richard Thomas, Llanelly, Carmarthenshire; Augustus Willoughby Thornton, Dublin; James Turle, Richmond Villas, Holloway; George Clarke Wilson, Dublin.

June 3:—Edwin Sercombe, Somer Place, Hyde Park; Robt. Bianchi, London; Henry Joseph Kelly, Frogna House, Hampstead; Nicholas Hardcastle, Newcastle-on-Tyne; George Jobbling, Morpeth; Edward Lodge Byers, Milford Haven; Samuel Woodall, Dudley, Worcestershire, Alfred Godley Crewe, Broad-sall, Derbyshire; William Powell, Dudley, Worcestershire.

APOTHECARIES' HALL:—PASS LIST. Thursday, May 26th, 1853:—William Cuthbert Blackett, Durham; Richard Carmichael Bourne, Dublin; Robert Anlezark Cunliffe, Garstang, Lanark; John Ivy Mais, Catterick, Yorkshire; James Earl Moreton, Marton Hall, Cheshire; William Hall Ryott, Thirsk, Yorkshire.

Thursday, June 2, 1853:—John Maule Sutton, Greenwich; George Edward Young, Gosberton, Lincolnshire; Henry Leach, Trinity Square, Southwark; Rowland Smith, Boxted, Suffolk; Robert Westcott, Middlesex; John Mayor, Cardell, St. Columb, Cornwall.

APPOINTMENTS.

[*An asterisk is prefixed to the names of Members of the Association.]

CORNISH, W. R., Esq., elected Resident Surgeon to the Royal Sea Bathing Infirmary, Margate.

*DESMOND, L. E., Esq., elected one of the Surgeons to the Liverpool Dispensaries.

FOLKER, William H., Esq., elected House Surgeon to the North Staffordshire Infirmary, Etruria, Staffordshire.

LEARED, Arthur, M.B., elected Physician to the Metropolitan Dispensary.

LOWNDES, —, Esq., elected one of the Surgeons to the Liverpool Dispensaries.

*THOMPSON, Henry, M.B.Lond., M.R.C.S., appointed (on the 1st June) Surgeon to the St. Marylebone General Dispensary, in the room of Charles Bacon, Esq., resigned.

WILLIAMSON, Joseph, M.D., appointed by the Senatus to be Lecturer on the Practice of Medicine in the Medical School of the University and King's College of Aberdeen.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were Members of the Association.]

CREAM, George, Esq., Surgeon, at Long Melford, Suffolk, aged 70, on June 4.

FOOTE, Alfred, Esq., Surgeon, formerly of Kew, on board the *Columbus*, of rheumatic fever, aged 39, on May 10.

KIRBY, John, LL.D., Surgeon, formerly Professor of the Practice of Physic to the Royal College of Surgeons, Ireland, at Newtown House, Rathfarnham, County Dublin, on May 26.

LUCAS, Henry Carr, Esq., Staff-Assistant Surgeon, late of H.M. 80th Regiment, and formerly of Exeter, at Chatham, on May 27.

PONSFORD, John, Esq., Surgeon, formerly of Moretonhampstead, Devon, at Exeter, on May 30.

SHAND, James, Esq., Surgeon, after a short illness, at his residence, Hallhill, Turriß, Aberdeenshire, on May 29. Mr. Shand was a generous hearted man, and a skilful practitioner.

*STILWELL, Arthur, M.D., at Moorcroft House, Hillingdon, Middlesex, on June 6.

BOOKS RECEIVED.

[*An asterisk is prefixed to the names of Members of the Association.]

BELLINGHAM, O'B., M.D. A TREATISE ON DISEASES OF THE HEART. Part I. pp. 252. Dublin: 1853.

COCKS, J., M.D. SEA-WEED COLLECTOR'S GUIDE. 12mo. pp. 120. London: 1853.

*DAVEY, James George, M.D. ON THE NATURE AND PROXIMATE CAUSE OF INSANITY. pp. 76. London: 1853.

GOSSE, Philip Henry, A.L.E. NATURALIST'S RAMBLES ON THE DEVONSHIRE COAST. Plates. pp. 451. London: 1853.

SEATON, Joseph, M.D. THE PRESENT STATE AND PROSPECTS OF PSYCHOLOGICAL MEDICINE. pp. 23. London: 1853.

ERRATUM.

At page 485 of last number, column 2, line 24, the words "becomes lessened" should be "varies"; and the word "direct" should be "inverse". The sentence will then read as follows: "Still more, there is every required proof that the attraction of every molecule of matter for another molecule varies in an inverse ratio to the square of the distance".

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London; or to the office of the Journal. Letters requiring immediate attention and revised proofs ought invariably to be sent to Putney.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XXIV.

LONDON: FRIDAY EVENING, JUNE 17, 1853.

NEW SERIES.

GENTLEMEN WISHING TO JOIN THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION ARE REQUESTED TO APPLY TO THE GENERAL SECRETARY, TO THE BRANCH SECRETARIES, OR TO THE EDITOR OF THE JOURNAL. The Annual Subscription is One Guinea. Members receive the Journal free by post.

The ANNUAL MEETING will be held at Swansea on the 10th and 11th of August. Gentlemen who have communications to read to the Meeting are requested to give notice of their intention to the Secretary. Communications will be called for in the order in which the Secretary has received notice from the respective authors. Vide p. 470 of May 27 for various details.

THE LAW OF ENGLAND TAXES AND TORTS MEDICAL MEN WHILE IT PROTECTS MEDICAL PRETENDERS.

On June 3rd, we made a few remarks upon a recent trial at Edinburgh of two quack doctors who had been swindling the public by styling themselves "Botanical Physicians", and pretending to cure all diseases by certain nostrums, sold at some shillings each. It was not contended by the public prosecutor that the practice of the prisoners was positively dangerous, nor that it had in any known case proved fatal; but a conviction was obtained from the jury upon the charge of "falsehood, fraud, and wilful imposition", and the sheriff pronounced upon the impostors sentence of "nine months imprisonment with hard labour". As a contrast to the wholesome jurisprudence of Edinburgh, let us place before our readers some gleanings from the newspapers of the week, analogous to others of frequent occurrence, especially on this southern side of the Tweed.

Our first example is a case of suspected manslaughter by a Coffinite. The following is the newspaper paragraph.

"COFFIN PRACTICE. Thomas Clarke, a pilot, aged 53, died recently at West Hartlepool after treatment for hernia by a practitioner said to be of the Coffin School, who promised 'to make another man of him', and with that view gave him heroic doses of medicine. 'The masterpiece of the complaint', he said, 'was wind': and he administered jalap, Cayenne pepper, and gin—a dram-glassful every morning. Mr. Atkinson of West Hartlepool said, in reply to a question by the coroner, that the medicine could do no good: that it had induced vomiting, purging, and debility, and had in this way caused or hastened the fatal issue. The jury returned a verdict of 'Natural death'."

The chances are, that the jury was, as is usual in the Coroner's Court, a party of idle cronies of the beadle, and that the trial was, as is also very usual in the Coroner's Court, a mere farce. Had the Coffinite quack been a gentleman and a qualified practitioner, he would most probably have been sent to prison on the charge of manslaughter. If a homœopath or a Coffinite kill a patient, he is almost invariably acquitted; but if by accident or through ignorance a legal practitioner, acting conscientiously for the best, lose a case, and a popular excitement be created, he rarely escapes the vengeance of the vulgar.

As regards the death of the poor pilot, we have not much doubt as to its cause; but, even granting that the

medicines did not contribute to the fatal issue, is it honest in the Government of this country to levy fees on the stamps of diplomas, which diplomas, in place of being any protection to their possessors, are positive sources of danger, while the want of them is received as an evidence of ignorance, and therefore as a ground of exculpation from malapraxis? It is undoubtedly safer in England to be without any diploma; and this is well understood by the London venerealists, most of whom advertise as surgeons and doctors under assumed names, and without any legal qualification. This remark brings us to our next example; but as many of our readers may be ignorant what a Coffinite is, we may stop for a few minutes to afford a brief explanation.

Coffinites, Thompsonians, and Botanical Physicians, are synonymous terms designating the members of a sect of quacks, who are as well known and as wide spread in the United States of America, as are homœopaths and venerealists in London. The party is not without its apostles in England, as appears from the report we have just quoted. In London it is less known than in some provincial towns, where it bids fair to be the most successful medical imposture of the day. The text book of the Coffinites is now before us: it is entitled "The Practice of Medicine on Thompsonian Principles, by J. W. Comfort, M.D." The volume is a portly octavo of 582 pages, professing to be a fourth edition, and bearing the imprint of "Lindsay and Blakiston, Philadelphia: 1853." Thompsonian quackery maintains several journals in America, and one in London.

The "psora" of Hahnemann has a counterpart in the "canker" of Thompson; and the great aim of the Botanical Physicians is to get rid of this canker. "Dr. Thompson", we are told at p. liv, "introduced into general use in his system of practice a class of remedies for removing the canker or vitiated secretion that forms on the stomach and bowels to a greater or less extent in all cases of disease, and interrupts the process of digestion, and tends to prostrate all the functions of the stomach, and constitutes a general cause of the continuance of disease." So much for the theory. The practice chiefly consists—ostensibly at least—in administering lobelia. Many quacks, however, (like Curtis and Campbell,) use nostrums of their own, employing the names of Thompsonianism or Botanical Medicine only as popular baits for weak-minded valetudinarians, just as rubbers, hydropaths, Mesmerists, etc., etc., call themselves homœopaths, because homœopathy has been diligently associated in the public mind with cocoa for breakfast, and tasteless globules under curious names. But here, to avoid expansion, we shall at once quote a few lines from Thompson's own account of lobelia. "In giving" he says, "a description of this valuable herb, I shall be more particular, because it is the most important article made use of in my system of practice—without which it would be incomplete, and the medical virtues of which, and the administering of it in cases of disease, I claim as my own discovery." The newspaper report which we quoted above is evidently

imperfect; for the following is the Coffinite or Thompsonian practice in strangulated hernia. "The use of the vapour or warm water bath, and relaxing the system by giving the patient freely of lobelia, and administering it also by injection and retained, constitutes the treatment most likely to overcome the stricture." This extract affords a glimpse at Coffinism, a system which, if practised as it is preached by its apostles, is an atrocious system of wholesale poisoning. Nevertheless, Coffinism enjoys more protection from the law of England than scientific medicine.

It may be said that, if people choose to be poisoned by lobelia, the law ought not to place any hindrance in their way. That proposition we do not concur in; but we have not space or inclination at present to refute it.

We therefore proceed to speak of the advertising veneerists, who by calling themselves doctors and surgeons, and by the use of various other fraudulent practices, entrap shoals of juvenile victims, whose uttermost farthing they extort by threats of exposure, and by frightful pictures of maladies which have often no real existence. Here the law might protect society without infringing the liberty of the subject; for, if Parliament decreed that all legal medical practitioners should be registered, the swindlers to whom we are now referring would at once find that their trade was ruined. It would no longer be possible for the London manly-vigour-scoundrels to advertise as members of the medical profession; and we should not have a coroner at Sheffield saying that it was less a crime in a man whose real name was Davis, and who was not a surgeon, to practise as "Dr. Henry and Co., Surgeons", than for simpletons to employ him, as is stated in the report of the inquest, to be found in a subsequent page. Nor should we have a quack fencing with a Scottish judge as to the meaning of the letters M.B.—whether they mean Medical Officer of the parish of B., or Bachelor of Medicine. The scene to which we refer is described in Dr. Turner's sound and right-hearted appeal, in this week's Letter Box.

We call attention in this place to the fraudulent use of medical titles, because its immediate suppression would protect many inexperienced persons, without diminishing the facilities of the public for employing quacks as quacks. It is indeed a great hardship that this small shred of protection should be withheld from medicine, till harmony be created in what Lord Palmerston calls the "chaos of the medical corporations". In the meantime, pharmacy has obtained the registration boon; for, by the 13th section of the Act of last Session, persons not registered as Pharmaceutical chemists, who call themselves Pharmaceutical chemists, are liable to a penalty of five pounds. Any man may call himself M.D., M.B., or Surgeon, without incurring any risk of punishment, or violating any law!

The consequences of this position of affairs are alarming to contemplate. From various towns and villages throughout the country, we have received information of the general practitioners being likely, ere long, to be supplanted by "pharmaceutical chemists": and we believe that it is strictly true to say that at this moment there is going on a disastrous retrogression towards the state of affairs prior to 1815, when the practitioners of medicine consisted of two utterly distinct classes—the highly educated physicians, a small, select body, who ministered to the wealthy, and a servile herd of ignorant apothecaries, who were considered good enough for the poor, but who were not expected to treat the upper grades of society, except under

the orders of one of the superior grade. The accomplished general practitioners in medicine, surgery, and midwifery were then unknown; and if, as at present, they continue to be insidiously supplanted by the prescribing "pharmaceutical chemists", they are likely in another generation to be entirely rooted out. We have more to say on this subject: but in the meantime we conclude by asking our readers to reflect upon this undeniable truth, that while medical men are taxed for their diploma stamps, persecuted in Courts of Law, and tormented in the performance of their professional avocations by the inroads of quackery and counter-practice, quacks and counter-practitioners are free from impost, and enjoy protection in their unjust callings.

FOUR STRONGHOLDS OF QUACKERY IN THE FOURTH ESTATE.

ONE of the most discouraging features of the times in connexion with quackery is the facility with which portions of the press can be seduced to circulate the manifestoes of charlatans; and another cause of sorrow is the apathy with which our profession regards the dissemination of pseudo-medical periodicals, and tolerates those quasi-professional men who basely purchase the praises of these prints, by clandestine and ignoble compacts.

There are in the Fourth Estate four strongholds of quackery, to which at present we particularly wish to direct attention, viz. :—

- I. NEWSPAPERS, especially those published in the Provinces and in the Colonies;
- II. RELIGIOUS (?) PERIODICALS;
- III. PSEUDO-MEDICAL PAPERS; and
- IV. MEDICAL JOURNALS.

A standing order from half a dozen quacks for the insertion of their long advertisements, and an agency for their medicines, are with nine of every ten provincial and colonial newspapers necessary elements of existence. A paper with a limited local circulation, and a small number of legitimate advertisements, requires assistance from the advertising quacks; and the money which a provincial or a colonial newspaper receives from them is its chief sustaining pabulum, when the richer bribes of contested elections and local feuds cannot be grasped. Piles of provincial and colonial newspapers are now before us, the majority of which are actually choked with the knavish and often indecent advertisements of notorious medical swindlers. Many of these papers have been sent to us accidentally, in consequence of their containing obituary notices and miscellaneous articles of medical intelligence; and in few of them can we trace any symptoms of open war with the regular profession. We have found also, upon careful and extensive inquiry, that these papers, containing the fraudulent declarations of pill-cheats, and the beastly blackguardism of veneerists, circulate freely both at home and abroad, in the family circles of the high and the low, of the rich and the poor. To speak the truth plainly, the literature of the brothel is introduced regularly and systematically into the parlour and the boudoir; and thus with the maiden and the matron, with the virtuous and the vicious, obscene expressions suggestive of impure thoughts are made

"Familiar in their mouths as household words".

Surely, the piety and the gallantry of England might be induced to join with legitimate medicine in a determined

league to dislodge the venerealists, with their body and soul destroying lures, from family newspapers; and if these journals cannot be induced by moral suasion to reject these abominations, let them be starved into submission by all honest men refusing them admission into their homes. Let a brand of infamy be placed upon their readers and subscribers.

Some, we know, affect to believe that the familiar exhibition of vice is a preserver of virtue; just as others of kindred bias assert, that witnessing the nudities of the *ballet* invests the male and female aristocracy of England with a chastity of heart, speech, and behaviour, which can only find a parallel in ancient Lacedæmon, where similar displays were sanctioned.

"Old Sparta, sternly virtuous, made
The pure and spotless maiden
To join the wrestler's ring, by naught
But nature's vesture laden.

"No crimson hues along the cheek
Arose to mar her beauty;
Why feel dishonest shame, if true
To honour and to duty?

"Nor word, nor look, betrays the fire
Which in the bosom gathers
Of Lacedæmon's youths, who sit
Beside their warlike fathers."*

Poets may so write: but medical practitioners know human nature too well to believe that the passions of youth are so controllable. They have penetrated deeply into the recesses of many a broken heart, and learned from many a victim of premature senility, that the first introduction to vice, and to those who pander to it, has been through the pages of the family newspaper. Purity of thought is in both sexes the outpost of chastity; and if we wish our wives and our daughters to take rank with the Portias and Cornelias of society, how can we allow them—nay, compel them almost—to read the advertisements about "manly vigour" and "sexual debility", with which the newspapers are teeming? We ask earnestly, and in the hope of receiving an answer in virtuous and united action,—Why do husbands and fathers purchase these poisonous and indelicate writings, and allow them to taint the purity of the domestic sanctuary?

It is not upon mere professional grounds that the quack ought to be driven from their great stronghold, the provincial and colonial newspapers. Public morality demands this; and public opinion might, we are confident, be easily made to accomplish it. If there is no man in Parliament who will ceaselessly agitate this question till redress be obtained, we must get some one to enter Parliament with this special mission—and such a patriot statesman is much wanted at the present time—a man who understands in all their gigantic and catholic bearings the medico-political and sanitary questions of the day.

The Religious Periodicals constitute another stronghold of quackery. What is popularly designated the "religious" press, is preeminent as the accomplice of the medical quack. All sects seem equally to participate in this iniquity. We can trace no difference in this respect between Protestants and Papists, Churchmen and Dissenters. With a very few honourable exceptions, the publishers of religious periodicals

seem to be so blinded to all decency by their thirst for profit, that the piety and morality of the interior of their publications forms a violent contrast to the impiety, fraud, and filth displayed upon their wrappers. Probably the explanation of the degraded condition of the religious press lies in the fact, that the works complained of are mere trade speculations of mean capitalists, who look upon religious readers, and quack advertisers, equally and only in the light of parties to be conciliated for the sake of their cash.

In the *Edinburgh Christian Magazine* for April last, there is an article entitled "Medical Quacks, with special reference to the Working Classes". In this paper, irregular practitioners are forcibly and unsparingly denounced; as will appear evident to the reader of the following extract.

"To patronize quackery seems nothing less than to deny the wisdom of God's arrangements in the world, and to act on principles which are true only on the supposition that there is no order, no law, no government; but that all is confusion and chance, amidst which a fool may succeed, or pick up truth as well as a wise man."

After perusing with pleasure these and kindred sentiments, we proceeded to examine the wrapper of the magazine, when, behold! there met our eyes in flaming capitals

"HEALTH FOR A SHILLING!"

heading the details of one of the *soi-disant* Professor Holloway's "extraordinary cures". Alas! alas! it is indeed more easy to preach than to perform the obligations of religion and morality. To the speculators of the *Edinburgh Christian Magazine* we would say, "Deeds and not words!" Wash your hands, gentlemen, from the unhallowed gains of quackery, and remember that you yourselves have truly written, that to patronize quackery is to deny the wisdom of God.

Pseudo-medical Papers, as many of our readers may know, are maintained in London by homœopaths, hygeists, chronothermalists, Mesmerists, hydropathists, and Coffinites. Each of these sects has its own organ: and several individual quacks support and disseminate journals for their own trade. Speaking generally, there is a close alliance among all the quack journals, and most of the open charlatans, as well as quasi-medical authors, use all of these papers avowedly or under the rose for keeping their names before the public. It is not only, however, by the advertising columns and notices to imaginary correspondents, that the friendly understanding among the various denominations of medical sharpers is illustrated. The *Homœopathic Times*, for example, espouses multifarious and theoretically opposite forms of quackery. In *Coffin's Botanical Journal* for the 4th of June, in a leading article upon the "Doctors' New Reform Bill", we read the following paragraph. The capitals and italics we may premise are those of the original.

"When we see any danger of this Bill passing, our friends may rest assured we shall soon inform them of it, in order that petitions against it may be sent from every city, town, and village in Great Britain. This will be the time for action and UNION among Homœopaths, Hydropaths, Mesmerists, Medical Botanists, etc., to fight and conquer their common foe allopathy; the supporters of which system have, according to one of their own body, Dr. Frank, 'slaughtered thousands in their quiet sick rooms'."

The pseudo-medical press is a stronghold from which it is not to be supposed that quackery can ever be dislodged; but

* SAVIOLI, as rendered in U. S. Lit. Gaz.—Vide Longfellow, p. 601.

the profession can materially weaken it, by disowning those false brethren who clandestinely accept the meretricious blandishments of its commanders. On a future occasion we may examine with some minuteness the bastard medical journals, with the view of unmasking or testing the reality of certain disgraceful alliances which are commonly believed to exist between them and persons who wish to pass current as respectable authors and practitioners. In the mean time it is important for the profession and the public to be frequently and distinctly told, that there are some six or eight journals published in London, under the medical ensign, which make a piratical display of our colours only that they may the more stealthily pounce upon and plunder their victims.

And now we come to speak of the shortcomings of the Medical Press. Here, the faults are occasional and not systematic—as often, perhaps, the results of inadvertence as of commercial seduction; yet they are of too serious a character to be passed over in silence. Without, then, breaking new ground, we shall briefly recall attention to the dishonest advertisement regarding Pulvermacher's chain.

The exposure which resulted from Dr. M'Intyre's remonstrance with ourselves is, probably, fresh in the recollection of many of our readers. Our article upon the improper use of Dr. Golding Bird's name in Mr. Meinig's advertisement of the chain appeared in our paper of 15th April, to which we refer those who may have forgotten all the circumstances. The principal facts were these—that as the advertisement contained a certificate purporting to “be published with the kind permission” of Dr. G. Bird, but which certificate was actually published in opposition to that physician's remonstrances, and with a gloss upon it which he explicitly repudiated, we refused to allow it again to stain the JOURNAL OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION. We were gratified to find that the *Medical Times* (although a commercial speculation of non-medical capitalists) responded to Dr. M'Intyre's appeal in a spirit similar to our own. That paper contained the following creditable notice upon the 7th of May, at p. 480:—

“The advertisement referred to was inserted in this Journal without any knowledge on our part that Dr. Bird's name had been improperly used. We beg to inform Dr. M'Intyre, that directions have been given to refuse insertion to Mr. Meinig's advertisements of Pulvermacher's Chain for the future.”

We do not know whether Dr. M'Intyre appealed to the *Lancet*; but we find in that Journal for June 4th, the very same advertisement which was justly felt to be a pollution to the advertising pages of the ASSOCIATION JOURNAL and *Medical Times*. To the *Lancet* we repeat what we said to the *Edinburgh Christian Magazine*, “Deeds, not words”! If you denounce quackery in vehement leaders, do not sell it a shelter in your advertising columns!

Upon future occasions, it is our intention to throw strong lights upon the strongholds of quackery in the fourth estate; because we believe that by following such a course we shall be able to drive some detachments of the enemy from their intrenchments, and to seize and punish various parties of renegades and pirates.

DR. BRIGHT AND HOLLOWAY'S OINTMENT.

A COPY of a printed handbill of Holloway which was circulated at Manchester, by his agent in that town, is now before us. It gives a report of “a case abandoned by Guy's, the Metropolitan, King's College, and Charing Cross Hospitals, London.” This report is in the form of “an affidavit sworn to before the Lord Mayor of London”; and contains the following passage. The capitals and the italics are reprinted as they appear in the handbill.

THE DEPONENT, thereupon, called on DR. BRIGHT, chief Physician of Guy's, who, on viewing deponent's condition, kindly and liberally said, “*I am utterly at a loss what to do for you, but here is a half sovereign, go to Mr. Holloway, and try what effect his Pills and Ointment will have, as I have frequently witnessed the wonderful Effects they have in Desperate Cases! You can let me see you again.*”

There can be no mistake as to the Dr. Bright who is meant, as the description applies to none other than the well-known Richard Bright, M.D., F.R.S., Physician Extraordinary to the Queen, and Consulting Physician to Guy's Hospital. We ask the following questions on behalf of some gentlemen residing at Manchester, who feel aggrieved by the wide circulation which the handbill from which we have quoted has had in their town. They very properly state that the handbill is calculated to injure their position and usefulness, because Dr. Bright is well-known as an eminent physician, and as Physician Extraordinary to the Queen, the Royal Lady whose stamp is profaned by being printed “by order of the Government” upon all the pots and pill-boxes of Holloway.

- I. Did Dr. Bright give the advice which is imputed to him in the handbill?
- II. If Dr. Bright did not give that advice, has he ever taken any means of preventing his name from being used to the dishonour of that profession, to which he owes the high reputation which he now deservedly enjoys?
- III. What steps ought to be adopted by medical practitioners, to disconnect the medical profession from participation in the adventures of Holloway and other persons of the same class, whose superb equipages are maintained by “money obtained by false pretences”—by barefaced swindling?

To the first question we venture, without authority, to reply in the negative. The others are not so easily disposed of.

DISCUSSION ON QUARANTINE AT THE EPIDEMIOLOGICAL SOCIETY.

It is not often that we report a more temperate discussion, than that which took place on Monday, the 6th inst., at the Epidemiological Society, on a subject which, of all others, is loaded with the most conflicting opinions.

The paper of Dr. Milroy, and the observations upon it, by the epidemiologists who commended or criticised it, lead us to the painful conclusion, that our ideas as to the spread of great pestilences are as vague in this day, as were the ideas of those who discussed the same subject when Mead, and Pringle, and others long before their time, were the distinguished occupants of the scientific arena.

The Caliph Omar, most uncharitable monster, said of the ladies, that they were great evils, but that the greatest of all evils was that they were necessary. Had the Caliph lived in this day, and supplied the words, "scientific discussions", for the word "ladies", he would have spoken much more worthily as a successor of the prophet, and much more to our taste, and idea of truthfulness. Can anything, for example, be more distasteful and at the same time more necessary than discussions on the value of quarantine? Honest and competent men have for centuries past been inquiring into the origin of pestilences; and yet, out of every six of these men with whom one may commune, three shall be found offering incontestible proofs that pestilential disorders come in on the right hand, and the remaining three offering proofs as incontrovertible that the same disorders come in on the left. The story of the chameleon controversy is forced on the mind as it meets these differences and difficulties, together with the moral of the story, viz., that both parties, perhaps, are right, and both wrong, and that both will continue in the same unsatisfactory predicament, until some leading fact, as yet hidden, comes to the light and explains the causes of difference.

We briefly allude to the subject of quarantine on this occasion, hoping to be able to discuss the matter at greater length at some future day. Meantime we direct the attention of all our readers to the importance of the subject, and repeat a remark made by Dr. Milroy, that "until the question of the value of quarantine has been settled in a satisfactory manner by the medical profession, a great duty which the profession owes to the world, and which it alone can perform, remains unfulfilled."

ORIGINAL COMMUNICATIONS.

CONTRIBUTION TOWARDS A PATHOLOGICAL HISTORY OF UTERINE "VIVACES".

By EBEN WATSON, A.M., M.D., Professor of the Institutes of Medicine, Andersonian University, Glasgow.

M. LEVRET, in the *Mémoires de l'Académie Royale de Chirurgie* for 1777, published an elaborate paper *Sur les Polypes de la Matrice et du Vagin*, in which he makes mention of a kind of polypus under the name of "vivaces".

The following is an abridgement of his description of them. They are, he says, ordinarily unattended by lancinating pains, or by sanious discharges, such as occur in malignant diseases of the uterus; but they cause frequent hæmorrhages, like common polypi. They differ from them, however, in having no enveloping membrane, or, at all events, a very delicate one. They are found in two forms; either like *digital vegetations*, more or less long, thick, and numerous, parts of which break off, and come away from time to time with a hæmorrhage; or they may be found in one mass, somewhat globular in form, and rendering the womb large and painful; and, though the vagina be found full of this mass, the womb is not at all emptied of it—"ainsi, comme il est communément impossible de parvenir à détruire la cause immédiate de ces fongosités, c'est peine perdue de travailler à les retrancher." "Ces excroissances", he writes at another place, "doivent être censées incurables, parceque ces ne sont que trop communément des végétations de quelque ulcère de l'intérieur de la matrice."

M. Herbiniaux, in his *Traité sur divers Accouchements laborieux, et sur les Polypes de la Matrice*, published at Brussels in 1794, gives a more lengthened account of vivaces. He expresses the same opinion with M. Levret, of their origin and incurability. He says that he never found

them single; i. e., more than one tumour always occurred in the same case; and they were sometimes in the vagina as well as in the uterus. The former are easily recognised by the touch, but the latter are more difficult of diagnosis. He accordingly gives the following marks as distinctive of uterine vivaces:—1. The tumour is almost always *within* the womb; because, not being attached by a pedicle, it is not permitted to escape from the viscus, except in a few cases, in which it grows from the neighbourhood of the cervix uteri. 2. The os uteri is more or less open, and the tumour which remains inside is felt by the finger to be soft, and less united than the common polypus. 3. The womb is so voluminous as to form a tumour in the hypogastrium; and, during the whole course of the disease, that external tumour is very painful; while the vivace is insensible when touched through the os uteri. (*Op. cit.*, vol. ii, p. 39).

M. Levret mentions having had several cases; but, strange to say, he does not give the details of any. M. Herbiniaux has given the particulars of two cases. The subject of one was an old lady, aged seventy-four years, in whom the disease had existed for three years, and who had been worn to a shadow by frequent and severe hæmorrhages, one of which, when M. Herbiniaux was called, had lasted for forty-eight hours. He found a tumour presenting in the orifice of the uterus, free from its walls, of the size of an orange, and with a very *short pedicle*; so that he could not move it in the uterus. It was soft, and its surface was irregular.

Considering this tumour a vivace, and that the constitution of the patient was already affected, seeing that the nostrils were filled with polypi, M. Herbiniaux declined operating; but, being urged, he yielded, and applied first one ligature and then another. The state of the patient was almost immediately improved by this measure. The tumour separated on the seventh day after its strangulation, but grew again; and the woman died at the end of six months.

M. Herbiniaux does not mention the age of his other patient, nor the duration of the disease. When he first saw the case, there were two tumours, each of the size of a hen's egg, in the vagina, with almost no necks. The orifice of the uterus was open, and its walls, as far as could be felt with the finger, were healthy; but there was a swelling in the hypogastrium, extremely painful on pressure. This he considered to be the body of the womb, swollen and inflamed. He applied the ligature, and the tumour came away; but others similar to it soon formed; and the woman died in about four months afterwards.

Dr. Gooch relates a case of vivace at p. 300 of his work on the *Diseases of Women*. The subject of it was seventy years of age, and had for only a few weeks been terrified by the occurrence of several profuse hæmorrhages. Dr. Gooch found the os uteri dilated to the size of half a crown, *with thin edges*, and a substance slightly protruding through it. It had a rough cauliflower feel, and bled on being touched. It was round and large. "I could", he says, "pass my finger within the orifice, and some way up between the thin walls of the uterus and this globular body." The tumour never projected enough into the vagina to admit even of its tip end being included in a ligature. About eighteen months afterwards, the patient died dropsical. "Since this case," he adds, "I have seen two similar to it."

Dr. Jas. Hamilton, in his *Practical Observations* (part i, p. 51), mentions a case which fell under his observation. The subject of it was mother of three children, and "*not above thirty-three years of age*." She had been for two years subject to hæmorrhages when Dr. Hamilton first saw her. He "removed the excrescence, and applied various local remedies to the uterus"; but with only temporary benefit. She, however, lingered for two years after the commencement of his attendance, and died in great suffering.

Dr. D. D. Davis also relates a case, which was probably of a similar nature with those just given. (*Principles and Practice of Obstetrics*, vol. ii, p. 610). The tumour in this case grew very rapidly, and filled the whole pelvis before the lady expired. No inspection was made.

Dr. Bullen, of Cork, records two cases under the name of cauliflower polypus; but they appear to have been identical with vivaces, although the symptoms were of a somewhat doubtful kind. In each case, the tumour originated from the inner part of the cervix, and in one case, it implicated part of the margin of the orifice. It might, therefore, have been easily mistaken for the true cauliflower excrescence of the os uteri. (*Dublin Quarterly Journal of Medicine*, vol. xxv, p. 414.)

The following case, which I venture to class along with those already noted, occurred to me some years ago:—

CASE. The patient had never been married, and was about forty-five years of age. She had always enjoyed good health, and had menstruated regularly till three years before I saw her, when the function ceased to be performed.

About Christmas 1848, after leaping from a table, hæmorrhage to considerable extent took place from the womb, and a bloody discharge had continued to flow constantly and profusely, but varying in its colour, sometimes being bright red, at others less so, until I saw her on the 9th of August, 1849. At that time, her chief complaint was of intense pain in the lower part of the abdomen; so intense, indeed, that she could not lie still in bed, but rolled about from side to side. The lower part of the belly was very tender and painful on pressure; but, on examining *per vaginam*, I could discover no abnormality of the uterine neck. The womb was quite moveable, and did not seem to be enlarged; and it had no tendency to expulsive contractions—a fact which seemed to indicate that there was no polypus of any great size within the organ. These circumstances were all confirmed by my father, who examined the patient, at my request, the day after my first visit.

Seeing, then, that the pulse was full and quick, the pain great, and the tenderness of the abdomen excessive, we came to the conclusion that, however the hæmorrhage was to be explained, we had at present to deal with a severe attack of acute metro-peritonitis. Our patient was therefore cupped and blistered over the sacrum; and, as her digestive organs were very much in fault, she took a mild course of mercury with opiates and laxatives. She used the tepid, and ultimately the cold water hip-bath, with vaginal injections of the same fluid. By these means, the pain was completely removed; and I put her on a tonic plan, and recommended change of air.

She accordingly went to reside on the sea-coast, at Helensburgh; and I heard no more of her for nearly three months: she then again consulted me. Her general health was much improved since I had last seen her, and the pain had never returned; but I was astonished to learn that she still had a constant bloody discharge and frequent profuse hæmorrhages. On examining *per vaginam* I now found the uterus distended by a growth within it, so that the neck was rendered thin and tense, with a small hole—the os uteri—in its centre. Through this I could pass my finger, and I felt a soft, granular, roundish body occupying the interior of the womb. I could pass my finger nearly round the growth; for it was unconnected with the anterior wall of the uterus as far as the finger could reach; but I could not reach its back part.

A few days afterwards, I had the advantage of consulting both with Dr. James Wilson and with my father. On that occasion, I used a uterine bougie, which passed freely between the growth and the uterine wall anteriorly, but not posteriorly. The case was so far therefore clear. The patient had a growth of a soft, granular nature, distending the womb, and apparently attached by a broad base to the interior of its posterior wall. My consultants recommended me to dilate the os uteri, in the hope that the tumour would descend into the vagina, so as to admit of the more easy and effectual application of a ligature round its base.

The ordinary methods of dilatation gave my patient great pain; and I had obtained the consent of the experienced gentlemen above named, to slit up the thin and tense cervix uteri, and apply a ligature round the tumour *in situ*, when the patient was attacked by severe diarrhoea, which

soon rendered her condition hopeless. She, however, lived for several weeks, during which the uterine discharge became thick, grumous, and extremely foetid. She died about the middle of January 1850.

On inspection, I found the intestines matted together by the lymph of old inflammatory effusions. The solid viscera were pale and bloodless. The uterus was enlarged to five or six times its usual bulk in the virgin state; its walls were thinned and hardened throughout their whole extent. The cavity, internally, was occupied by a mass of long fungoid vegetations, matted together, but apparently springing individually from a sloughy, rather than an ulcerated, portion of the posterior wall. The whole was so softened and infiltrated with foetid pus, that it was quite unfit for more minute examination.

Perhaps I may now be allowed to generalize some of the chief features of vivaces, as these may be gathered from the preceding isolated observations.

In the first place, then, vivaces generally indicate their presence suddenly and without previous warning. There are no symptoms as yet recorded, from which any physician can infer their presence within the womb, until a discharge of blood occurs; and even then the diagnosis is obscure. The excessive pain in the lower part of the belly, taken along with the profuse hæmorrhages, seems, at this period, to be the only mark fitted to excite a suspicion of the real nature of the case. But we are not kept long in suspense, for the progress of the growth is always very rapid. Within three months, in my case, it had fully distended the womb. The physical signs are then sufficiently marked; viz., the bloody discharge, the stretching of the uterine neck so as to form a tense diaphragm with an aperture in its centre, and the granulated and insensible growth, felt through it, fixed by a broad base to some part of the internal surface of the organ.

The termination of the case has hitherto been invariably fatal, sooner or later: death being caused either by gradual exhaustion, or, more rapidly, by the occurrence of colliquative diarrhoea, which is the common liberator of the victims of inveterate uterine disease.

What, then, is the nature of this growth? Is it composed of vegetations from an ulcerated surface, as supposed by Levret, or, is it identical with the cauliflower excrescence of Dr. Clarke, as has been asserted by Dr. Gooch?

In attempting to answer this question, I would observe that I do not regard the obvious difference of position or site as establishing any essential difference between vivaces and the cauliflower excrescence. At all events, as Dr. Gooch has remarked, they do not, in that respect, differ from each other “more than polypus of the neck and orifice from polypus of the fundus of the uterus”. And Sir B. Brodie’s case, referred to by Dr. Gooch (*op. citat.*, p. 304), would seem to be an instance of the occurrence of the cauliflower excrescence *within the womb*.

But, while I acknowledge that the growth just named may occur, though very rarely, within the uterus, still I believe that certain marked differences exist between it and vivaces. The most important of these is the pre-existence of ulceration of the internal surface of the uterus. This occurrence was very clearly evinced in the case, which I have narrated as having occurred in my practice, by the pain and tenderness on pressure above the pubes. But I must confess that the profuseness of the hæmorrhage, at this stage of the affection, remains unexplained; nor do I know of any circumstance capable of throwing light on the phenomenon. There was no evidence, at that period, of a growth within the womb; and the pain of the fundus uteri was not felt until after several severe hæmorrhages. If we could suppose that some one or more enlarged and atheromatous vessels had been ruptured by the shock of the patient’s fall, and that the wound, thus occasioned, ulcerated instead of healing, we might, perhaps, explain the history of the case: and, although it is a theoretical, it is the only feasible explanation I am able to give. But, however this may be, there can be no doubt of the reality of the case.

matory action which speedily ensued, and which, though actively treated, terminated in vegetations.

On the other hand, the cauliflower excrescence of Dr. Clarke is seldom accompanied by pain; indeed, I may say, never by pain so severe as that which precedes the formation of vivaces. The former is a still more insidious disease than the latter: and hence Dr. Clarke, in his original paper, lately republished by the Sydenham Society,* informs us that he had never found it less in size than a blackbird's egg.

Another remarkable point of distinction seems to flow from the preceding. It regards the nature of the discharge. That from cauliflower excrescence is generally limpid and watery, hardly soiling the linen, and becomes only occasionally bloody, as at the menstrual periods, which are not often disturbed at the first, or after some violent bodily exertion, capable of breaking the delicate structure of the growth. Whereas, in cases of vivaces, the discharge is either bloody or purulent, and ere long it becomes very fetid; evidently proving the much greater amount of vascular action going on in the latter than in the former instance. The watery discharge from the cauliflower excrescence seems to be a mere mechanical transudation of serous fluid mixed with the increased mucous secretion of the irritated vagina, and sometimes, also, with the cast off cells of the growth itself. In all such cases, too, when hæmorrhage occurs, small brainy masses may be found in the discharge, identical in structure with the cauliflower excrescence. Such hæmorrhage, therefore, is likewise mechanical, flowing from ruptured substance of the growth. But it is far otherwise with vivaces. They often die and come away as putrid matter, but never seem to break from delicacy of structure; and the hæmorrhage in these cases must proceed either from the progress of the original ulcer, or from the smaller vegetations from its surface, which still retain their vascular nature. The longer and more bulky growths are to all appearance *evascular*, being white and spongy, and filled with cheesy substance like concrete pus. For, as I remarked above, the ordinary discharge, in cases of vivaces, is always purulent when it is not bloody; this, of course, arises from the progress of the ulceration; which is continually sustained and prevented from healing by the mass of its own unhealthy vegetations.

This leads me to mention, as a fourth distinction between these two kinds of uterine growth, that vivaces do not shrink in bulk after death, as happens in such a remarkable manner with the cauliflower excrescence from the os uteri. But I regret that, for reasons formerly mentioned, I cannot speak with precision on the minute internal structure of vivaces. If, however, I am warranted in concluding from the history of such cases, especially those points in it to which I have just adverted, that vivaces are nothing more than exaggerated vegetations from an ulcer of the womb, matted together by inflammatory effusions, and perpetuating the morbid lesion from which they originated, then nothing can be more different than their internal structure compared with that of true cauliflower excrescence. For, as I have elsewhere more fully explained (*Edinburgh Monthly Journal of Medicine*, for Nov. 1849), the latter growth consists of a congeries of simple and compound cells, some of which are expanded into delicate bags containing blood-corpuscles. These bags exist chiefly on the margin of the excrescence; and when they burst, they leave the fibrils or hair-like processes, which mark the latest period of its history. It seems to be the peculiar property of these cells to withdraw serum from the blood in the uterine vessels, and to permit its exudation through their walls, thus constituting the greater part of the discharge. But of course this ceases at death; and then the cells collapse, or in other words the excrescence shrinks away. But no such function is performed by vivaces, and no such shrinking occurs in them after death; and therefore I do not think the inference unfair, that no such mechanism exists in them as in the cauliflower excrescence.

* Essay on Diseases peculiar to Women.

I have not hitherto introduced the question, whether or not vivaces are malignant in their nature. The opinion of Levret as to their being incurable, and some of the cases recorded by Herbiniaux and others, would seem to indicate that such really was the case. But I am inclined to think that vivaces may or may not be malignant, according to the character of the ulcer from which they spring. This opinion is founded on that which has already been stated and proved, with such data as I possess, regarding the pathological significance of the vivaces themselves: and I think it unnecessary to enlarge upon this point at any greater length. Suffice it to remark, that on this important feature of the case will depend the prognosis and the treatment.

I do not assert that all cases of malignant disease are incurable, when I say that malignant ulcer of the body of the womb belongs to that category. Its advance is generally considerable before it is clearly diagnosed, and even then it is out of the reach of efficient means of eradication. And when the vivaces have sprung from a non-malignant ulceration, it may still be impossible to root out the morbid parts before the patient's condition has become a hopeless one. In some cases, however, it may be attempted by ligaturing the long vegetations—making the cord cut as well as strangulate the growth,—and then cautiously but effectually applying a caustic substance. I should myself prefer the common caustic, because its action, as well as the bleeding, might be conveniently arrested by injections of vinegar and water. As soon as possible thereafter, alteratives and tonics should be given to change and improve the action of the internal surface of the womb. But I feel that I cannot, with propriety, even attempt to frame directions for the treatment of vivaces; and I therefore leave it to others to draw the practical inferences deducible from the preceding pathological data regarding that very rare but most interesting affection of the uterus.

Glasgow, June 1853.

METHODS OF EXPRESSING THE PHENOMENA OF AUSCULTATION.

By W. O. MARKHAM, M.D., Assistant Physician to St. Mary's Hospital.

NOTHING more fully demonstrates, if any demonstration of the fact were needed, the incompetency and faultiness of our present methods of expressing the phenomena of auscultation, than the circumstance, that each successive writer upon the subject finds himself compelled, as he proceeds in his task, either to criticize, or alter, or entirely renovate the existing nomenclature as it falls into his hands. The particular terms of it fail to express, or express but feebly, his idea, or, perhaps pervert it altogether; or they are made to indicate something very different from their essential meaning. The structure is thus, in his sense, weak, and he endeavours, by patching, to brace it up for his occasions. How comes it that he falls in being more successful than his predecessors?

If our view of the case be correct, there is a radical defect at the very bottom of our present system, inherent in it, and of necessity tainting every part; so that each addition and alteration, which is made in the direction of the original idea which presided at its establishment, is but a conversion or an engrafting of one defect into another. When a superstructure bears marks of weakness, is it unreasonable to suppose that its basis must be at fault? In the matter of auscultation, I believe that the truth of this may be readily shown. On this point, however, I do not wish to linger here, as I intend soon to bring the subject somewhat more fully before the profession. I would, however, venture briefly to suggest as a remedy for the manifest evil referred to, the adoption of a nomenclature founded on the rational system of observing auscultatory signs, which has been promulgated by the modern German school.

I need hardly observe, that our present method of no-

menclature is essentially French; and like the French, it is founded on the supposition, that to each auscultatory sign a distinct pathognomic value should be affixed. The modern German method abhors this idea; it asserts, (and I believe it would be hard to prove the negative of the assertion,) that there are very few, if any, auscultatory signs which are pathognomic of any one particular pathological condition of the internal parts, and of that alone. It is contented to record the sign as it presents itself to the ear, in the plainest and simplest terms. It calls fine bubblings such, not unwarrantably premising them to be the crepitating *râles* of pneumonia, and thereby prejudging and forcing the observer's mind towards, it may be, a faulty diagnosis; the real value of those fine bubblings it seeks elsewhere, extrinsically to the sign itself. Auscultatory signs, after this manner of viewing them, become in the physician's mind the resultants of certain physical causes, of reciprocal actions between fluids and solids, and as such to be calculated and measured according to the ordinary laws of sound, not converted into sure and positive exponents of particular morbid states. The German method takes us as far as physical facts warrant us in advancing; the French leads, and has led us, to a pretence of knowledge far beyond what facts justify us in assuming. The one keeps auscultation in its place, using it as a handmaid to diagnosis; the other makes it a master-key, of itself sufficient to unravel the knowledge of disease.

I am far from assuming that the nomenclature which I here present, in accordance with these principles, is not open to many objections; but of this I feel assured, that the adoption of some similar method will alone enable us to find a way to escape from those errors, which in my belief must of necessity attach themselves to our present system.

PROPOSED METHOD OF AUSCULTATORY NOMENCLATURE.

1. *Respiratory Murmur.*

- a. Vesicular. { Feeble, loud, smooth, coarse, distinct, interrupted, etc.
- b. Bronchial. { Feeble, loud, smooth, coarse, distinct, interrupted, etc.
- c. Respiratory murmur, accompanied by metallic echo or amphoric resonance.
- d. Indeterminate respiratory murmur.

2. *Vocal Resonance.*

- a. Indistinct humming.
- b. Thoracic voice. { Weak.
Loud.
- c. Bleating voice.
- d. Voice accompanied by metallic echo and amphoric resonance.

3. *Dry and Moist Sounds heard during the movements of the Respiratory Organs.*

- a. Dry Sounds. { Hissing.
Whistling.
Sonorous.
Crackling.
Clicking.
Friction.
- b. Moist Sounds. { Fine. } Scant; abundant; accompanied by metallic echo and amphoric resonance.
Small.
Large.
Bubbles. {
Gurgling.
- c. Indeterminate dry and moist sounds.

I shall not entrench on the space of the *ASSOCIATION JOURNAL* by entering into a full explanation and defence of the above terms. To a certain extent they speak for themselves. I know very well that such a nomenclature will find no favour with the admirers of "*ampullæ et sesquipedalia verba*"; and that it may be advantageously modified there can be little doubt; but I maintain that the principle on which it is founded is good, and must sooner or later be generally admitted.

The original communication of Dr. Theophilus Thompson,

which lately appeared in the *ASSOCIATION JOURNAL*, is the cause of my making these observations. It is satisfactory to find that the modern German plan of viewing the phenomena of auscultation is already working its way amongst us, though I cannot congratulate Dr. T. Thompson on his having arrived at any successful application of it; for, by his proposition, much leaven of that faultiness, for which it is substituted as a remedy, is still retained. I am, however, pleased to find an authority like Dr. T. Thompson enforcing the necessity of our coming to some clearer comprehension of this matter; and I am gratified that he should have used as his reasonings for the necessity thereof, the ideas collected together by myself in the preface to a translation of Skoda's work on *Auscultation*, etc. I feel rather anxious to place this last remark upon record, as otherwise it might hereafter seem, and especially to the readers of the proposed paper to which I have alluded, that I had copiously borrowed my reasonings from Dr. T. Thompson.

Clarges Street, Piccadilly, June 3rd, 1868.

OBJECTIONS TO THE USE OF CHLOROFORM.

By SAMUEL BEECROFT, Esq.

SINCE the use of chloroform has become so general, and so much is written in our periodicals in its praise, and so little against its use, I hope that I shall escape the charge of presumption in venturing on the following remarks.

I would first state my doubts of its use being beneficial in any case, when we know that its effect in lulling pain is produced at the expense of the blood being poisoned by the introduction of an excess of carbon; under which state there is great disposition to the production of local congestion. I appeal to common sense, if a patient in this condition and undergoing an operation is so likely to do well, as one in whom it has been the care of the surgeon to keep the blood as healthy as possible.

For my part, I feel sure that convalescence cannot be so certain when chloroform is used, as when the blood is free from its poisonous agency. But some will say, that we have evidence to the contrary in the fact of patients constantly making rapid recoveries when this anæsthetic agent has been used, and I cannot deny that such recoveries do take place. But, we know that a great many would recover if they were rendered insensible with alcohol; but we should not like to risk operating under these circumstances; and we find a great analogy in the action of spirituous drinks and chloroform. Death is produced by large and rapidly administered doses of each; and we find in both instances, after death, the same congestion of vital organs.

I have frequently used chloroform, and I confess that I have never seen it the means of accelerating the convalescence, as is stated by some. How can rendering the blood impure cause a rapid recovery? The supposition is absurd. I have, however, often seen headache, sickness, etc., produced by it for some time after its use; and I have the impression that in some cases I have read, where death has occurred a few days after operating, it might in some measure have been owing to the chloroform.

The last two cases in which I used it were, hydrophobia, and dislocation of the humerus into the axilla of seven weeks standing. In the case of hydrophobia, the patient was certainly quieted by it, but he died in less than twenty-four hours after the first active symptoms of the disease set in; and in all the cases I have read, where it has been used, this disease appears to have run its course very rapidly. In the case of dislocation, although we put the patient in great jeopardy, by the chloroform causing convulsions followed by stupor, under which the muscular system was completely powerless, we yet failed in the reduction; and if I were again to fail after bleeding, etc., in reducing a dislocation, I should have no hope of succeeding with chloroform. I give these two examples, as this agent has been so strongly recommended in the treatment of similar cases.

Having attended a good share of midwifery, and having

been frequently called on by my medical friends to operate, I may be allowed to state that I have never seen one case of labour in which I should desire, or think it right to use chloroform; even when instrumental or other aid was required. I would nearly as soon in natural labour see my patients tipping themselves into patience, as produce this condition by repeated small doses of chloroform.

Although, probably, my opinion is not worth much, as to its use in operative surgery, from the small number of capital operations I have had, yet I do not speak altogether without data; for I have occasionally operated and assisted in operating in cases of hernia, amputations (one at the shoulder joint), lithotomy, etc. I am sure it has been far more satisfactory to me to see patients, although suffering, in their senses, than to be annoyed by constant anxiety lest some untoward circumstance should occur from the chloroform. I also think that the recoveries were rendered more certain by not using it.

I observe that, in the last number of the *ASSOCIATION JOURNAL*, Dr. SNOW writes, with his accustomed ability and moderation, "*On the administration of Chloroform during Parturition.*" He does not, however, conclusively prove to my mind, that the supposed ill effects resulting from the use of chloroform, in the cases which he has been candid enough to bring forward, did not arise from its use. I cannot think that any one can be out of danger, although it may not be perceptible to us, who has inhaled two ounces and a half of the vapour of chloroform. Unfortunately, although, in commencing its administration, we may intend to give small doses only, yet, if the desired effect be not produced, we are apt to go on until sufficient has been used to become dangerous.

With respect to the action on the foetus, of chloroform inhaled by the mother, most writers agree that the child is influenced by it. If this opinion be correct, another objection arises against its use; for assuredly we have no right to run the risk of permanently injuring the offspring, that we may relieve the temporary sufferings of the mother.

Hyde, near Manchester, June 6th, 1853.

BIBLIOGRAPHICAL NOTICES.

THE PROGRESS OF IMPROVEMENT IN THE TREATMENT OF CONSUMPTION AND OTHER PULMONARY AND LARYNGEAL DISEASES. By JAMES TURNBULL, M.D., Physician to the Liverpool Royal Infirmary. pp. 74. London: 1853.

THE MEDICATION OF THE LARYNX AND TRACHEA. By S. SCOTT ALISON, M.D. pp. 49. London: 1853.

UPON few subjects in medicine has the opinion of the profession undergone greater change, within a very limited time, than upon the medical treatment of consumption. A few years ago, this disease was regarded as a hopeless—a necessarily fatal one. The steady advance of what may be termed rational medicine, has, however, sufficiently proved that, in phthisical cases not a few, our art is not altogether fruitless; that, in some instances, even a cure is possible; whilst, in many, urgent symptoms may be arrested, and the patient, for a time at least, restored to comparative health. In the treatise before us Dr. TURNBULL seeks to place such a conclusion upon a permanent basis, by recording from his own practice the histories of a number of consumptive cases, which were more or less benefited by remedial agents.

Cod-liver oil, tar-water, creasote, naphtha, and the seeds of *annanthe phellandrium*, were severally used by the author in the treatment of his patients. The oil, however, seems to have been his chief remedy; the rest having proved themselves inoperative upon the primary disease, and capable only of relieving some of its symptoms.

After carefully perusing Dr. Turnbull's cases, we consider that, although illustrating no new principle of treatment, they afford additional proof that much may be effected, even under circumstances apparently most unpropitious, by the

judicious combination of hygiene and medicine. "It is," observes the author, "in the early stage of consumption that most can be done to avert the disease." This opinion is contrary to that of the illustrious Laennec, but it is one upon which all modern authors seem to have agreed.

After a brief advocacy of topical medication of the larynx, and a chapter containing practical suggestions on the "Employment of Inhalations in Consumption and other Pulmonary Diseases", the author concludes his valuable report with some judicious remarks upon the hygienic and dietetic treatment of phthisis. He proposes as an article of diet for the consumptive invalid, a much wasted and hitherto untried substance—sugar of milk.

In the other little work before us, the author commends to the still further use of the profession, the now rapidly increasing practice of applying nitrate of silver to the interior of the vocal organs; and records in an instructive manner his own observations upon a similar use of other substances, such as olive oil, glycerine, cod-liver oil, mucilage, and morphia.

Sir Charles Bell* was the first who ventured to apply the nitrate of silver to the laryngeal mucous membrane. The practice was followed up by the late Mr. Vance and others, but was never extensively adopted, until Dr. Horace Green, of New York, proved to the profession both its practicability and its safety. It has long been employed as an auxiliary to other treatment by some of the physicians of the Consumption Hospital at Brompton; and many practitioners are gradually becoming converts to its employment.

Although we are not disposed to question the possibility of the operation, we cannot help thinking that Dr. SCOTT ALISON has scarcely placed its performance in a proper light. He tells us, "the moment I find the ribs begin to rise in the inspiratory act, that moment I introduce the sponge into the mouth, and, clearing the tongue, at once pass it with the greatest facility through the glottis down into the larynx, and, if need be, into the trachea, and then immediately withdraw it". Without doubting the author's success in this particular, we should quake for the result, were many of his readers to venture thus unceremoniously to treat their patients. The sensibility of the glottis, like that of other organs, varies of course in different persons: in a few, perhaps, the sponge may be at once introduced; but, in others—and these the great majority, we are satisfied, from some experience in the matter, that it cannot. Dr. Horace Green, and, we believe, most of his disciples, advise that the larynx should be *gradually* approached, and thus become accustomed to the presence of the irritant. With this view they recommend the first, or the second, or even sometimes the third application to be limited to the external parts of the laryngeal opening; and that the introduction of the sponge into the larynx itself should be reserved for a future operation. A soft brush liberally supplied with the caustic solution, and rapidly passed around the pharynx, answers this purpose admirably. On one occasion, where some such preparatory treatment had not been adopted, we witnessed extreme and alarming distress on the part of the patient. Not unfrequently there are certain mechanical difficulties attending the operation. The tongue, in many persons, is very thick and large at its base, and so conceals the epiglottis, that the passage of the instrument is uncertain, and in some few cases, perhaps, almost impossible. We have found, as a general rule, that, unless the epiglottis can be fairly brought into view, and drawn a little forwards by depressing the tongue, the passage of the sponge is very difficult to accomplish. For this reason, we think that the practice recommended by Dr. S. Alison, of using no tongue-depressor, but simply of directing the patient to inspire deeply, will never be generally adopted.

We have ventured these few remarks from a sense of duty, lest the success which has attended the author's mode of operating should lead others either into rash practice, or, into complete scepticism, from disappointment at the results.

* Institutes of Surgery.

Hitherto, we believe, no other agent than nitrate of silver has been applied to the larynx. The profession is therefore indebted to Dr. S. Alison for his experiments on the use of other substances. In many instances, much good is effected by the mere presence of the sponge itself, quite independent of any medicinal application. Thick mucus may thus be removed from the glottis, and the respiration of the patient materially facilitated. Yet it is reasonable to suppose that the parts lower down may oftentimes be either stimulated or soothed, with no little advantage, by the judicious use of topical remedies. We hope that the success which has attended Dr. Scott Alison's experiments in this particular may be equalled by that of others, who may be tempted to follow him in his practice.

THE SUBJECT-MATTER OF A COURSE OF SIX LECTURES ON THE NON-METALLIC ELEMENTS. By PROFESSOR FARADAY. Arranged, by permission, from the Lecturer's Notes, lent for the occasion. By J. SCOFFERN, M.B., etc. etc. pp. 293. London: 1853.

We have here a revised reprint of a series of Lectures which appeared in *The Chemical Record* towards the end of its short career; a journal which, at one time, had our best wishes for its success, on account of the extent of its foreign scientific intelligence, and the rapidity with which it was presented to the English reader—qualities which, had they been but persevered in, would, we think, have soon procured for that journal a permanent and gradually increasing body of subscribers.

We gather from the preface, what indeed remains very evident in the body of the treatise, that the notes of Dr. FARADAY have been "expanded" by the editor, serving, in many cases, as texts for him to discourse upon; so that the lecturer's share of the work has been confined to handing over his lecture-notes to the editor, with permission to amplify and otherwise adapt them for publication. Should the great Electrician ever run his eye over the pages before us, he will, we opine, be made more chary of granting such permission for the future.

We have seldom met with a book in which the claims to praise and blame have been more equally balanced. It merits both—and both in no small measure. We may safely assume, although there are no sign-posts of type set up to distinguish the original from the "expanded" matter, that the "General Introduction" is wholly from the pen of Dr. SCOFFERN. Whether this introduction is written for the tyro or for the advanced student, we are unable to determine, it being in many parts so simple and elementary as to be readily comprehended by one previously unacquainted with chemistry, sketching in a pleasant, easy style the progress of the science from its earliest dawn to the present day, whilst the descriptions are conveyed in unstilted and even elegant language; qualities so rare in books of a scientific nature, as to lend a double zest to its perusal. Dr. Scoffern fairly carries his pleased reader along with him, until the two stumble on such a section as that devoted to the Atomic Theory and the doctrine of Atomic Volume. This section, as well as that on Chemical Symbols and Notation, will, we suspect, effectually puzzle students, unless they be already familiar with these subjects; a class of readers for whom we do not gather this book to have been especially intended.

This occasional obscurity of expression arises, it seems to us, from the editor not having thoroughly imbued himself with that special characteristic of Faraday's method of teaching, so constantly displayed whenever he lectures; viz., the habitual and anxious care to thoroughly develop the principles of the subject in hand, and to clear the ground before him; never ascending to recondite science until he has explained, in apt and easily understood language, the elementary laws on which his deductions and discoveries are founded. This advantage—a vast one—the listener to these lectures has enjoyed over him who shall now sit down to a perusal of them; since we are well assured, from our knowledge of this admirable custom of the pro-

fessor, that the former had patiently expounded to him whatever was requisite for him to be acquainted with to enable him to grasp the lecturer's meaning; whilst the reader's knowledge and familiarity with technical terms is far too much taken for granted, in this endeavour to enable him to surmount the difficulties of the somewhat abstruse doctrines of atomic weight and volume—doctrines which, in our experience, so frequently prove the *pons asinorum* of the chemical student.

This difficulty in the book before us is needlessly aggravated by carelessness in correcting the press, "weight" being confused with and used instead of "volume", in page 34. This is not, we regret to say, the sole instance of important errors of this nature, which, unchecked as they are by any table of errata, so far as we have been able to find, must greatly mystify and confuse the student. One more instance of similar carelessness and we are quit of our duty in this matter. In page 57, describing the modes of preparing oxygen gas, the following occurs, to fathom the meaning of which will defy an adept, let alone a student:—"Process II. By exposing to a red-heat binoxide or peroxide of manganese in an iron retort. Theory of the process: *Manganese in acid, to its acid combinations, forms with oxygen three oxides, viz.—*

	Manganese Equivalents.		Parts by Weight.	
	Ma.	Ox.	Ma.	Ox.
Protoxide of Manganese	1	1	28	8
Sesquioxide of Manganese	1	1½	28	12
Binoxide, or Peroxide of Manganese	1	2	28	16

In the binoxide, half an equivalent of oxygen is so loosely combined, that it is evolved on the application of heat, and sesquioxide of manganese remains." The italics are our own. Over leaf, under "Process III", the details given of the decomposition are utterly irreconcilable with the diagram subjoined, which evidently belongs to, and was intended to illustrate, "Process II".

Having discharged our conscience in this matter—for we are free to confess that we could not see errors in print of this nature connected with and in some measure sanctioned by the name of Faraday, without protest—we may revert to a far pleasanter theme—the merits of this book; and these are neither few nor common. The style we have already alluded to; and we can well believe that Dr. Scoffern has, in numerous instances, succeeded in catching the very expressions which fell from the lips of this most winning and instructive of living scientific lecturers; one who combines the rare gifts of power to divine and elucidate the hidden laws of nature, with the ability of expressing both these laws and the phenomena to which they give rise, in language no less felicitous than are the experiments by which they are illustrated.

The first lecture, that on oxygen gas, would require to be quoted entire, to enable our readers to appreciate the mode in which the attention may be riveted by a scientific exposition, without producing any sensation of weariness or difficulty to the student. In our judgment, this book conveys (apart from the blemishes alluded to) a greater amount of information respecting the non-metallic elements, imparted in language so simple and comprehensible as greatly to aid memory in her task and to make this study easy and agreeable, than any treatise we have met with; and could Dr. Scoffern contrive to remedy the carelessness we complain of in the present, or issue another and corrected edition, we do not know a book on the subject we should more heartily recommend than these "Faraday Lectures".

REMARKS ON HYSTERIA, IN CONNEXION WITH HYDROPHOBIA, AND OTHER CONVULSIVE AFFECTIONS. By JOHN DALZIEL, M.D. pp. 32. Edinburgh: 1853.

DR. DALZIEL states, that an outline of his pamphlet was published in the old *Glasgow Medical Journal* upwards of twenty years ago; and that the original is now reproduced to show the coincidence between his views and those of

Dr. Marshall Hall, which he believes to form a strong *a priori* argument in favour of their truth.

The author's views are briefly explained in the following propositions:—

"I. That the globus hystericus, as well as the similar affection of the throat in hydrophobia, occasioned by the idea, etc., of liquids, is a spasmodic stricture of the muscles of the throat (glottis), whereby respiration is obstructed.

"II. That obstructed respiration, whether suspended or impeded, occasions cerebral congestion, as well as that feeling of general uneasiness, designated sensation of suffocation, which attends the paroxysmal exacerbation in both the diseases under consideration; and III. That cerebral congestion, and the sensation of suffocation, separately or conjointly, may, especially in an irritable habit, occasion convulsion.

"Admitting the truth of these propositions, it naturally follows that, as a palliative measure in the treatment of hydrophobia, the operation of bronchotomy might be expected to ward off, or at least abate the violence of the convulsive paroxysm. And there are other consequences (afterwards to be noticed) equally, or still more injurious, which this measure would tend directly to obviate."

PERISCOPIC REVIEW.

MATERIA MEDICA, PHARMACY, AND THERAPEUTICS.

CHLORIDE OF BARIUM IN CUTANEOUS ERUPTIONS.

VARIOUS abnormal conditions of the system, accompanied by cutaneous eruptions, are treated in France by a nostrum bearing the name of *Lanth's Mixture*; which owes its medicinal properties chiefly to chloride of barium. We are not aware of any special advantages which chloride of barium possesses over arsenious acid in combination with potash or soda. The therapeutical results are very similar, as are also the poisonous effects of overdoses. Both are active poisons, and must therefore be prescribed and administered with great caution. Lanth's mixture is composed of

Chloride of Barium, three and a half grains;
Whyt's Stomachic Tincture, one ounce; and
Distilled Water, three ounces.

Whyt's stomachic tincture is prepared as follows:—Take three ounces of yellow bark; of gentian root and of orange peel each one ounce. Macerate these ingredients in a pint and a half of rectified spirit, with half a pint of cinnamon water.

In the London Pharmacopœia, we have the liquor barii chloridi, which is a solution of one drachm of chloride of barium in one ounce of distilled water. The dose is from five to ten drops, cautiously increased till giddiness or nausea are produced, when the dose must be diminished, or, if the symptoms be severe, the use of the medicine must be discontinued for a few days.

CHLORIDE OF BARIUM FOR THE PRESERVATION OF ANIMAL SUBSTANCES.

In connection with the above paragraph, it is not out of place to refer to a paper by M. BLAUDET, in the *Comptes Rendus*, of which the *Annals of Pharmacy* thus speaks:—

"It is well known that hyposulphate of soda and chloride of zinc have been used for injecting dead bodies. The author has poured blood into concentrated solutions of both these salts. In the course of fourteen days, with hyposulphate of soda, the blood was fluid and black, but decomposed. The chloride of zinc had precipitated the blood. The author then tried chloride of barium, and found that this salt prevented putrefaction, and preserved the blood in a fluid state. He believes that it can be applied for injecting dead bodies when it is desirable to retain their living appearances, because it hinders the putrefaction of the blood."

TRISNITRATE OF BISMUTH ADULTERATED WITH ARSENIC.

This medicine, so valuable in many forms of dyspepsia and diarrhoea, is often so carelessly prepared as to contain a quantity of arsenic more than sufficient to interfere with its therapeutic action, and to produce most unpleasant consequences.

The *Annals of Pharmacy* (January, p. 23) quotes the following remarks of M. Cornut, who has followed up the researches of M. Lassaigne:—"The bismuth commonly employed in the preparation of the trisnitrate of bismuth, contains a notable quantity of arsenic, and, to obtain a pure product, it is indispensable that the metal should be submitted to the process of roasting; and yet the manufacturers frequently neglect to perform this operation. For this reason, he thinks that the pharmacist should never dispense this substance without having first tested it, and especially when it is prescribed in large doses. He gives a process, at once simple and easy, for detecting arsenic. Moisten half a drachm of the trisnitrate of bismuth with a sufficient quantity of pure sulphuric acid, evaporate to dryness in a small porcelain capsule, wash the residue with a little distilled water, filter, and put into a Marsh's apparatus. A very simple one may be constructed, by passing a tube, drawn out to a point at one end, through the cork of a four or five-ounce bottle. Care must be taken to use materials of absolute purity, and not to apply the light too soon, or an explosion may take place."

BALSAM OF TOLU ADULTERATED WITH COMMON RESIN.

To detect this frequent adulteration, ULEX pours sulphuric acid on the balsam, and heats the mixture, when the balsam dissolves to a cherry-red fluid, without evolving sulphurous acid, but with the escape of benzoic or cinnamic acid, if no common resin is present. On the contrary, the balsam foams, blackens, and much sulphurous acid is set free, if it is adulterated with common resin.

CANE SUGAR SYRUP ADULTERATED WITH STARCH SUGAR SYRUP.

SOUBARAN shows, in the *Journal de Pharmacie*, that, by attending to the behaviour of sugar with caustic potash, and of dextrine with iodine and with alcohol, this adulteration can be detected. Cane sugar syrup does not change its colour when boiled with caustic potash: grape sugar syrup is blackened by the same treatment. When the syrup is reddened by adding a few drops of iodide of potassium containing a little free iodine, it contains dextrine. If the syrup becomes milky when shaken with twice its volume of alcohol, and deposits after some time a thick mass, then also the presence of dextrine is indicated.

TANNIC ACID A TEST FOR SULPHATE OF QUININE IN THE URINE.

Seven hours after sulphate of quinine has been administered to a patient, Dr. VIALE (*Journal de Pharmacie*) has been able to detect it in the urine by means of tannic acid. He has also detected it two days after it had been taken. Upon adding the tannic acid to the urine, an insoluble precipitate is formed, white with a greenish tinge. This precipitate ought to be first collected on a filter, and treated with boiling alcohol; then the alcoholic solution has to be filtered, and mixed with chlorine, and afterwards with ammonia: all the reactions characteristic of tannate of quinine can then be obtained.

TANNATE OF QUININE AND TANNATE OF CINCHONINE.

These vegetable alkaloids are at present attracting attention in France. They are described as being less unpleasantly bitter, and as equal or superior in therapeutic power, to the common preparations of quinine and cinchonine. M. BARRESWILL, communicated last year to the Academy of Medicine in Paris the processes by which he obtained these tannates: and Buchner, a German pharmacologist, describes an extremely simple method of manufacturing tannate of quinine, which is given as follows in the *Annals of Pharmacy* for June 1853, p. 160:—

"Cinchona bark, roughly powdered, is to be treated with six times its weight of common or household vinegar. After it has macerated during twenty-four hours, it is boiled, then decanted, and the residue is treated afresh with more vinegar. These several decoctions are to be mixed together, and filtered when perfectly cold; and to them is to be added an infusion of gall-nuts so long as a precipitate is formed. This precipitate is to be collected on a filter, to be then washed, and lastly, to be carefully dried.

"Although the tannate of quinine prepared in this manner is not absolutely pure, and therefore requires to be given in larger doses than the sulphate of quinine; yet Buchner considered this preparation as particularly to be recommended, both on account

of its cheapness in comparison with the more expensive drug, sulphate of quinine, and also from the simplicity of its manufacture, on account of the facility with which it may be prepared in almost all pharmaceutical establishments."

DISULPHATE OF QUININE WITH INFUSION OF ROSES.

The prescriber often orders disulphate of quinine with infusion of roses, and the dispenser knows how unsightly a mixture results from the combination, when he uses an infusion prepared according to the London Pharmacopœia. Mr. W. PLACE makes the following observations on this subject in the *Annals of Pharmacy* for April, p. 123:—

"Four fluid ounces of the infusion (according to the P. L.) on addition of disulph. quine, with about three drachms of tinctures, formed sometimes a slightly cloudy, and at other times a cloudy mixture, which became decomposed in a few days. The same ingredients, with the infusion prepared as below, formed a beautiful mixture, perfectly clear, and continued so, though made up repeatedly, upwards of two months without any decomposition whatever, and *always with the same result*."

"Pour boiling water on the petals, in a vessel previously warmed by being rinsed with hot water: let it macerate one hour, then add the acid, let it stand one or two minutes, stirring once to diffuse the acid, straining and adding the sugar, and use the warm infusion immediately. If the infusion be used cold, it will not be so satisfactory."

RAW MEAT AND RECENT BLOOD AS THERAPEUTIC AGENTS.

In the diarrhoea of young children, connected with anæmia, M. TROUSSEAU prescribes raw meat finely chopped and slightly salted. He attributes the medicinal properties of raw meat to the iron and manganese contained in the fresh blood. The *Presse Médicale Belge* says, that in Belgium it is a common custom, in some diseases, to drink bullock's blood in the morning before breakfast, while still hot, in increasing doses. Persons suffering from hæmoptysis, and exhausted by hæmorrhage, are said to rally rapidly by taking every morning half a pint of blood in the slaughter-house, before it cools. It is said that children take the blood readily; but that adults loathe it.

VESICATING OIL.

The *New York Journal of Pharmacy* (Feb. 1853) states, that the solubility of cantharidin in chloroform, suggested to Professor W. PROCTER the idea of using chloroform in combination with a fixed oil to obtain a convenient vesicating agent. He gives the following formula:—

Cantharides, in powder, one part.

Chloroform and

Castor oil, of each one and a half parts by weight.

Add the powdered cantharides to the mixture of chloroform and oil in a close vessel; after some hours, transfer the ingredients to a glass apparatus and displace in the usual way. The liquid is thus reduced to about two-thirds of its original bulk. A few drops of the vesicating oil so obtained will blister the skin to which it is applied in about eight hours. By placing oiled silk over the part on which the vesicating oil has been applied, the moisture of the skin is retained, and a blister more speedily obtained.

We have found that an ethereal solution of cantharidin acts much more rapidly than Professor Procter's oil; and that in less than one hour a good blister can be got by using it with the oiled silk as above described.

PRESERVATION OF IODIDE OF IRON.

The iodide of iron, as will appear probable from the sequel, is often administered in quantities which are inconstant and much too small to produce the desired effects.

One method, extensively employed, of preserving iodide of iron for use in medicine, is in the form of an aqueous solution in which a coil of iron wire is kept immersed. This method is given by Pereira. Pereira also remarks, that it is important to know, that by keeping a coil of iron wire in a solution of the protiodide, no free iodine or sesquiodide of iron is formed, although the liquid may be fully exposed to air and light; sesquiodide of iron is formed, but if the solution be filtered it is found to contain protiodide only.

In the *New York Journal of Pharmacy*, Mr. H. WURTZ shows that there is a formation of a subiodide of iron, and consequent abstraction of iodine from the solution. Pieces of iron wire

placed in contact with a colourless solution of iodide of iron, caused, in the course of a few hours, the deposition of a precipitate, which had a dark orange colour quite distinct from the dark brown colour of hydrated sesquioxide of iron precipitated from a solution of the protochloride of iron by metallic iron. This precipitate being washed with distilled water until the washings gave no indication of the presence of iron, was still found to contain much iodine. No quantitative analysis of the precipitate, however, was attempted, for it was found that the washings, which no longer contained a trace of iron, still gave, with nitric acid and starch, a strong iodine reaction, thus indicating that the subiodide of iron upon the filter, whatever its composition, was decomposed by the action of water and oxygen as soon as the neutral iodide of iron was washed out. This is probably the reason why previous observers have mistaken this precipitate for pure sesquioxide of iron, having continued washing the precipitate until the washing gave no longer an iodine reaction, instead of an iron reaction as in the plan adopted by me, and consequently, until all the subiodide of iron was decomposed, and nothing but sesquioxide of iron was actually left upon the filter. The washings, however, after the removal of the iodide of iron, gave no iodine reaction with starch until after the addition of nitric acid; iodine, therefore, could only have been present in the form of hydriodic acid.

After the above experiments were made, Mr. Wurtz found that he had merely been confirming an observation of the illustrious Berzelius. *Gmelin's Handbuch*, under the head of "Iodide of Iron", has the following:—"According to Berzelius, the brown powder, which is deposited upon exposure of aqueous protiodide of iron to the air, is not pure sesquioxide of iron, but a basic salt." It appears, therefore, that the method of preserving iodide of iron in solution, in contact with metallic iron, is perfectly fallacious. This remedy, if preserved in solution at all, should be kept in bottles hermetically closed.

DELICATE TEST FOR IODINE: HOW TO DETECT A MILLIONTH OF IODIDE OF POTASSIUM.

Comparative experiments have convinced Dr. A. OVERBECK that the following method for detecting iodine is the most delicate of any yet known:—

Some starch or sugar is poured into a test-tube with concentrated nitric acid, and heated over a spirit lamp very gently until a violent evolution of gas ensues. The spirit lamp is then removed, and the gas, which evolves without a continuation of the heat, is conducted into the fluid to be tested, to which a solution of starch has been added. If the fluid contains only a millionth of iodide of potassium, a blue coloration directly results. By a farther introduction of the gas, the iodide of starch precipitates in flocks, and deposits itself, when at rest, as a compact massy precipitate. In this way iodine was detected in many plants, particularly in the ashes of several ranunculuses.

NEW FORMS OF OLD PURGATIVES.

We advise our readers to use the following new forms of old purgatives:—

1. RESIN OF SCAMMONY. Its purity can be easily tested by its perfect solubility in alcohol. This tasteless medicine is taken very nicely by infants, if well rubbed up with milk. The dose for an infant is one or two grains—for an adult five or six grains.

2. JALAPINE. Dose from one to two grains. It ought not to be given alone.

3. ALOETINE. Dose from one to two grains. In ordinary constipation we find that a pill composed of one grain of jalapine, one grain of aloetine, and one grain of extract of ginger is generally efficacious. This small pill usually acts abundantly, and without griping.

4. CATHARTINE. One or two grains purge well, and seldom gripe. Cathartine is procured from the unripe berries of the *Rhamnus Catharticus*.

LEMON JUICE IN RHEUMATISM.

Dr. OWEN REES restates, in the *Medical Times* for June 11th, his views regarding the use of lemon-juice in rheumatism. He says that it is an antidote to the true rheumatic diathesis; and that the cases in which it fails are those in which there are complications and pathological differences. He states that the favourable action of lemon-juice is interfered with in acute rheumatism by, 1. Syphilitic rheumatism. 2. Gonorrhœal rheumatism. 3. A pseudo-rheumatic affection, occurring in connexion with purulent discharges not necessarily gonorrhœal. The more chronic cases of true rheumatism are less likely to yield to this remedy.

REPORTS OF SOCIETIES.

EPIDEMIOLOGICAL SOCIETY.

JUNE 6TH, 1853.

DR. BABINGTON, President, in the Chair.

THE QUARANTINE LAWS. BY GAVIN MILROY, M.D.

DR. GAVIN MILROY read an elaborate paper on the value of quarantine in the British ports since the beginning of the present century. After showing that the subject of quarantine had not been studied or written upon in a careful, extensive, and unbiassed manner, he observed that he discussed the question of quarantine in reference to plague, yellow fever, and cholera. He then gave, at great length, numerous examples in which the strictest quarantine, carried out in insulated places, had failed in checking the progress of those diseases. He remarked that until the question of the value of quarantine has been settled in a satisfactory manner by the medical profession, a great duty which the profession owes to the world, and which it alone can perform, remains unfulfilled.

DR. McWILLIAM said that the mode of introduction of the plague into Malta, in 1813, to which Dr. Milroy had referred, was obscure, but that the after course of the disease was obvious. The woman who waited on the first patient was a schoolmistress. She fell a sufferer, and from the children under her care the disease radiated. He instanced cases where a strict quarantine had kept out plague, and concluded by remarking that an American conference lately held at New York, and a similar conference held at Paris, had each recommended a system of moderate quarantine.

MR. RICHARDSON had understood Dr. Milroy to say, that the plague was propagated in the same way as typhus fever. He would like to ask Dr. Milroy what his opinion might be as to the manner in which typhus fever was propagated? Mr. R. would also inquire if Dr. McWilliam did not think that the American and French conferences had come to the resolution of recommending quarantine, from a feeling that the evidence for and against the measure was most conflicting, and that to recommend the continuance of the measure, was to err on the safer side, rather than from a decided opinion that quarantine was absolutely necessary?

DR. MILROY considered that typhus fever did not spread from direct contact, but from the inhalation of matters given off from the fever patient. In this way he supposed that plague also spread.

DR. McWILLIAM said, that whatever might be the feeling of the French conference, he was sure that the continuance of quarantine was contrary to the genius of the American people, who would not be actuated by any such feeling as that suggested by Mr. Richardson.

DR. JAMES BIRD was of opinion that the question of the origin of the diseases to which Dr. Milroy had called attention, was different from the question of the diffusion of those diseases after they had arisen. This point should always be kept in mind in discussions on quarantine.

MR. LORD believed that quarantine was positively useless. He thought that yellow fever and typhus fever were the same diseases, only modified in character by climate. He instanced several illustrations in which contact had not given rise to plague. Napoleon had once led his army over a plague district, and in order to supply his men with better clothes, had had the bodies of persons who had died with the plague exhumed, and had given the clothes from those bodies to his soldiers, who wore them without being affected. After giving several similar instances, he sat down, remarking that he was glad to see that Dr. Milroy wished for the abolition of quarantine, and hoping that the Society generally would express a similar opinion.

DR. MILROY explained, that he contended for a further investigation into the value of quarantine, and for a modification of it—not for its abolition.

DR. CAMPS would not abolish quarantine, but have a proper value attached to it. He hoped it would not go abroad, that the Society was of opinion that quarantine ought to be abolished.

MR. HUNT was confident that quarantine is not a certain protection against the spread of disease; but thought that more evidence on the subject was necessary before one could assert that the abolition of the system was necessary.

THE PRESIDENT had seen instances in which quarantine had seemed to prevent the spread of plague. A ship containing three patients with plague, had been forbidden entrance into

the harbour of an island in the Levant, on which he was staying. No person on the island took the disease. But the same ship went on to the island of Mitylene, was received into harbour there, and straightway plague commenced in Mitylene, and committed fearful ravages. He also knew of a convent in Cairo which escaped a surrounding plague, from the strict quarantine kept up by the monks. Moreover, nothing could illustrate the spread of the plague by intercourse better than the historical fact, that Mehemet Ali's army carried and diffused the disease through every country into which it passed.

DR. MILROY, in reply, said that he wished in his paper to illustrate the value of quarantine. He himself did not know of one instance in which it had prevented the spread of either plague, yellow fever, or cholera. He hoped that if any member of the Society could bring forward marked instances to the contrary, that that member would do so in a special paper.

ASSOCIATION INTELLIGENCE.

MIDLAND COUNTIES BRANCH.

The Annual Meeting of the Midland Branch of the Provincial Medical and Surgical Association, which now comprehends Leicestershire, Derbyshire, Nottinghamshire, and Lincolnshire, was held at the Town Museum, Leicester, on June 2nd, under the presidency of Thomas Paget, Esq. There were also present, J. Barclay, M.D. (Leicester); T. W. Benfield, Esq. (Leicester); W. Birdsall, Esq. (Northampton); C. Bowmar, Esq. (Leicester); J. Buck, Esq. (Leicester); W. Cantrell, Esq. (Wirksworth); A. Cooper, Esq. (Leicester); J. Crossley, Esq. (Leicester); W. Derington, Esq. (Leicester); B. Eddison, Esq. (Nottingham); S. H. Evans, Esq. (Derby); S. W. Fearn, Esq. (Derby); W. J. Franks, Esq. (Billesdon); F. Fullagar, Esq. (Leicester); William Gill, M.D. (Nottingham); H. Goode, M.D. (Derby); John Hitchman, M.D. (Derby); J. Hollings, Esq. (Leicester); J. Hunt, Esq. (Thornby); S. Hunt, Esq. (Loughborough); E. Ingram, Esq. (Boston); W. C. Irwin, M.D. (Leicester); P. A. Jackson, Esq. (Leicester); John Johnson, M.D. (Derby); J. Jones, Esq. (Derby); J. Kcal, Esq. (Melton); T. Macanlay, Esq. (Leicester); John Marriott, Esq. (Kibworth); J. C. Marsh, Esq. (Nottingham); W. May, Esq. (Leicester); Edwin Morris, M.D. (Spalding); G. B. Norman, Esq. (Ilkeston); E. Paget, Esq. (Leicester); J. Palmer, Esq. (Loughborough); T. Paterson, Esq. (Ibstock); W. H. Ransom, M.D. (Nottingham); J. C. Robinson, Esq. (Syston); G. Shaw, M.D. (Leicester); J. H. Spencer, Esq. (Hallaton); J. H. Stallard, Esq. (Leicester); G. Stanger, Esq. (Nottingham); F. Stevenson, Esq. (Loughborough); E. Welchman, Esq. (Southam); R. Whitchurch, Esq. (Melton); Joseph White, Esq. (Nottingham); J. C. Williams, M.D. (Nottingham, Retiring President); G. W. Wood, Esq. (Woodhouse-Eaves); S. Wright, Esq. (Mountsorrel); T. Wright, Esq. (Nottingham).

GENERAL BUSINESS.

DR. WILLIAMS, of Nottingham, took the chair at two o'clock, and immediately resigned it to his successor, THOS. PAGET, Esq., of Leicester, who begged, before taking it, to be allowed to move a vote of thanks to the retiring President, which was carried by acclamation, and acknowledged by Dr. Williams. The President then read an address, in which he touched on most of the interesting medical topics of the day.

While the routine business of the meeting was being transacted, a large number of the members left to visit the extensive works of Mr. Wicksteed, the engineer, who has undertaken the task of deodorising and rendering useful for agriculture the whole sewage of the town of Leicester. This was to be the subject of a paper by Mr. Buck.

REPORT OF THE COUNCIL.

The Report of the Council was then read, and, on the motion of C. W. Wood, Esq., of Woodhouse-Eaves, seconded by Dr. MORRIS, of Spalding, was adopted by the meeting. It congratulated the members on the success which has hitherto attended their meetings, and on the large accession of members during the past year—twenty-eight from Leicestershire, five from Nottingham, one from Lincolnshire, and one from Derbyshire. The following papers have been read at the various meetings:—

On an Instrument for Extracting Foreign Bodies from the Bronchi. By Mr. FEARN, of Derby.

On a Case of Tumour of the Male Breast. By Mr. SYMPSON, of Lincoln.

On the Medical Topography of Nottingham. By Mr. Jos. WHITE, of Nottingham.

On Intestinal Obstructions. By Mr. BROWN, of Wymeswold. (This paper was published, as an original communication, in the ASSOCIATION JOURNAL for February 11th, 1853.)

On the Comparative Value of several Forms of Galvanic Battery which have been recently used for Medical Purposes. By Dr. RANSOM, of Nottingham.

On a Case of Cystic Oxide Calculus. By Mr. STANGER, of Nottingham.

On two Cases of Cataract, as illustrating the Relative Advantages of the Operations for Extraction and Depression. By Mr. MARSH, of Nottingham.

On Erysipelas as a Local Disease. By Mr. HIGGINBOTTOM, F.R.S., of Nottingham. (This paper was published, as an original communication, in the JOURNAL for April 1st.)

NEW MEMBERS.

The following new members were proposed, and unanimously elected:—Nathaniel Whitchurch, Esq., Melton Mowbray; Thos. Macaulay, Esq., Leicester; and James Snow, Esq., Lincoln.

ELECTION OF OFFICERS.

Dr. MORRIS, of Spalding, moved, and E. INGRAM, Esq., of Boston, seconded,—

"That JAMES SNOW, Esq., of Lincoln, be President Elect for next year; and that the next annual meeting be held at Lincoln."

The resolution was carried unanimously.

The various Secretaries were then re-elected, and a vote of thanks passed to them.

INCREASE OF MEMBERS.

In acknowledging the vote of thanks, Dr. Barclay, the Leicestershire Secretary, said he had written nearly eighty letters to medical men in the neighbourhood, twenty-three of whom had declined, thirty-one had joined the Association, and twenty-eight had strangely not sent any reply. He also stated, that the number of members in Leicestershire last year was fourteen, and that it was now increased to forty-five.

CASES AND COMMUNICATIONS READ.

Dr. MORRIS, of Spalding, then read an interesting case of "Medullary Sarcoma in the Pelvis".

JOHN BUCK, Esq., of Leicester, read a paper on "A New System of Deodorising Town Sewage, at present being carried out on a large scale in Leicester".

Dr. RANSOM, of Nottingham, read a paper on "The Pathological Value of the Occurrence of Sarcina in Vomited Matters".

THE DINNER.

At 5 o'clock, the members dined together at the Bell Hotel, nearly sixty being present. The President was supported on the right by His Grace the Duke of Rutland, who, being in Leicester as colonel of his regiment of Militia, was the guest of the President, along with the Rev. E. T. Vaughan, Vicar of St. Martin's, Lieutenant-Colonel King, J. F. Hollings, Esq., S. Stone, Esq., and F. Wicksteed, Esq. Letters of apology were read from the Most Noble the Marquis of Granby; Sir H. Halford, Bart.; Sir A. Hazlerigg, Bart., etc.

After the usual loyal toasts,—the Rev. E. T. Vaughan replying for the "Bishop and Clergy", and the Duke of Rutland for the "Army and Navy",—the President gave "The Lord-Lieutenant of the County", which was drunk heartily with all the honours, and feelingly responded to by His Grace; who, in reply, proposed "Success to the Provincial Medical and Surgical Association, and the health of Thomas Paget, Esq., President of the Midland Branch". Then followed, "The ex-President—Dr. Williams"; "The President-elect—James Snow, Esq."; "The County Magistracy and Lieutenant-Colonel King"; "The Mayor and Magistrates, and T. Macaulay, Esq."; "The Gentlemen who have read papers, and Mr. Buck"; "F. Wicksteed, Esq."; "The Local Secretaries, and Dr. Barclay"; "The Infirmary, and other Medical Charities"; "Dr. Shaw"; "The Literary and Philosophical Society, and its President—J. H. Stallard, Esq."; "The Mechanics' Institute, and J. F. Hollings, Esq."

Owing to the distance that many members had to travel, the party broke up early, after a most pleasant evening, bringing to a conclusion what every one agreed to have been a most agreeable and successful meeting.

NOTICES OF BRANCH ANNUAL MEETINGS.

BATH AND BRISTOL BRANCH.

The Annual Meeting of the above Branch will be held on Thursday, June 30th, at the Medical Library, Orchard Street, Bristol, at 3 p.m., when George Norman, Esq., President, will resign the chair to Henry Clarke, Esq., President-elect.

The report will be read and the ordinary business transacted. Members having any communications for the meeting are requested to give notice of them to the secretaries.

The attention of the members is called to the mode of voting for the Council, whereby they will vote only for the vacancies in their own district. Members are requested to write their initials, or some mark, opposite the name of those they wish to ballot for; but not to mark more than four of the names in their section, otherwise the nomination paper will be invalid. The leaf with the names so marked is to be torn off and forwarded to the secretaries on or before Monday, June 20th.

The dinner will be at the White Lion Hotel, at half-past 6 o'clock. Dinner tickets, including dinner, wine, coffee and waiters, 14s. each.

JOHN COLTHURST, } Hon. Secs.
JOHN S. BARTRUM, }

METROPOLITAN COUNTIES BRANCH.

The Annual Meeting will be held at Mr. Lovegrove's Brunswick Hotel, Blackwall, on Tuesday, July 19th, at 4 p.m., precisely. The Members will dine together at 6 o'clock. Members who intend to dine are requested to furnish their names to the Secretary as early as possible, and not later than July 10th.

Tickets for the dinner 10s. 6d. each, including ices and dessert.

JOHN FORBES, M.D., President,
T. OGIER WARD, M.D., Hon. Sec.

N.B.—Members of the Association become Members of this Branch by paying an Annual Subscription of 2s. 6d.

LANCASHIRE AND CHESHIRE BRANCH.

The Seventeenth Annual Meeting of this Branch will be held at the Town Hall, King Street, Manchester, on Wednesday, June 29th. The Chair will be taken at Twelve o'clock precisely, by the President for the year, James Black, Esq., M.D., of Bolton.

Dinner will be provided at the Albion Hotel, at Three o'clock, for those Members and friends who signify to the Secretary, on or before the 28th instant, their intention of being present. Tickets, 7s. 6d., including dessert, etc., but exclusive of wine.

JOHN HATTON, Hon. Sec.

N.B.—The Council earnestly request that Members of the Association will become Members of the Branch, by paying the Annual Subscription of 2s. 6d., as they were enabled last year out of the surplus to grant £5 to the Benevolent Fund.

NORTH WALES BRANCH.

The Annual Meeting will be held at Holywell, on Tuesday, the 21st June, 1853, at half-past eleven in the forenoon.

D. KENT JONES, ED. WILLIAMS, Hon. Secs.

SUFFOLK BRANCH.

The Annual Meeting will be held at the Assembly Room, Ipswich, on Friday, the 24th of June.

The chair will be taken at 2 o'clock, by Robert Martin, Esq., of Holbrook.

JOHN KIRKMAN, M.D., Hon. Secretary.

SOUTH EASTERN BRANCH.

The Anniversary Meeting of the South Eastern Branch will be held at the Sussex Hotel, Tunbridge Wells, on Wednesday, 29th June, at 12 o'clock precisely; Isaac Hargraves, Esq., President. Dinner will be provided at half-past 4 o'clock.

PETER MARTIN, Hon. Secretary.

WEST SOMERSET BRANCH.

The Annual Meeting of this Branch will be held at Clarke's Castle Hotel, Taunton, on Wednesday, June 29th. Robert Burridge, M.D., President, will take the chair at 2 p.m., and will be succeeded by W. E. Gillett, Esq., President-elect.

F. HENRY WOODFORD, M.D., Hon. Secretary.

EDITOR'S LETTER BOX.

ASSOCIATION EXTENSION THE BEST HOPE OF THE MEDICAL PROFESSION.

LETTER FROM DR. TURNER TO THE EDITOR.

SIR,—Your article on the "Public Estimate of Medicine", in the ASSOCIATION MEDICAL JOURNAL for March 18th, conveys, I believe, a just representation of the position which our profession occupies with regard to the general community. As individuals, no doubt, each of us can point to a circle, more or less extensive, of attached friends and clients, who unhesitatingly confide to our guardianship their dearest temporal interests, duly appreciating and gratefully acknowledging the value of our services; but yet, in all matters which concern us as a class, and at the hands of our fellow-men in the aggregate, —our very personal friends aforesaid not seldom taking part with the rest of the world,—discouragement, disparagement, and injustice are, and have long been, our portion. There is no "discerning public" for the body medical. In the general eye, the assiduous cultivator of our science and the moon-struck theorist—the honest practitioner of our art and the knavish nostrum-monger—the true medicinal leech and the ugly imitation, whose *habitat* is the ditch by the way-side—hold an equal place.

Now, if this confounding of the real with the delusive—this fusion of the "sublime" with the "ridiculous"—obtained only among the uninformed and uninfluential, we might be encouraged to look hopefully to the growing intelligence of the age for the eventual recognition of our claims to higher public estimation. But, alas! the schoolmaster is not abroad in our cause; he is himself unable, or indisposed, to discriminate between the fine gold of Legitimate Medicine and the brazen counterfeit of Empiricism. Nay, even with some of the otherwise enlightened and the powerful, the base metal passes current when the pure ore is rejected. Homœopathy (mild assassin!) and Mesmerism have their lovers in high places; and indiscriminate Hydropathy has found its eulogist in the distinguished *litterateur*, and could claim as its patron the eminent statesman until he became its victim.

The members of our profession may regard their degrees or diplomas as the sufficient evidence of adequate preparation for the efficient discharge of their important duties; but the roguish advertiser of infallible remedies has a "voice potential", as prevailing in the public ear as the approving judgment of a Senatus or of a Court of Examiners. The possession of our cherished honours may be invaded in open day, without word or sign of disapprobation from the lookers-on. How an attempt at this kind of spoliation was made, and how this attempt was viewed by the judge with favour rather than condemnation, will appear from the subjoined extract, from a report of the proceedings at a Criminal Court, held the other week in a neighbouring county. The interlocutors are the sheriff of the county, the agent or pleader for the panel, and a medical witness for the prosecution.

"Agent. Does the M.B. appended to your signature in your report signify any medical qualification?"

"Witness. No."

"Agent. What is it, then? What does it mean?"

"Witness. It's my mark."

"Agent. What do you mean by it?"

"Witness. Nothing! Many a one has a mark, and that's my mark."

"Agent. Did you, in your precognition at ———, declare yourself to be a Bachelor of Medicine of Marischal College, Aberdeen?"

"Witness. No."

[The secretary to the Senatus of the University above-named was in attendance, ready to disprove the assertion referred to by the agent, had it been repeated.]

"Sheriff. Come, Mr. ——— (addressing the agent), that won't do. If you are to plead the incompetency of the witness, it must be done in another way."

"Agent. I wish to show, my lord, that the witness is not a Bachelor of Medicine, as he represents himself to be. I think it material for my client to show this; and if the witness will retire, I will explain to your lordship the line I mean to pursue in his examination."

[The witness was now directed to retire; and in reply to the agent's explanation that followed, the sheriff gave it as his opinion that "it was of little moment whether the witness was

a qualified practitioner or not." The witness having been recalled, the agent resumed.]

"Are you a Bachelor of Medicine?"

"Witness. No."

"Agent. Why then do you put M.B. after your name?"

"Witness. The letters mean 'Medical Officer of the parish of B——'."

"Sheriff. This person has a right to put anything he pleases after his name, and it may be of consequence to him that it should be known he is Medical Officer of the parish of B——. I really do not see anything to detain us here."

Note or comment on this most edifying colloquy were superfluous, and I offer it as a companion-picture to that with which you have presented us in the JOURNAL for April 29th, culled from the pages of the *Church and State Gazette*, or *Churchman's Family Newspaper*. The judge's patronage of the pirate, and the ecclesiastical journalist's slanderous innuendo, have a common object in view—the public depreciation of the doctor.

In sober earnestness, is not this war of the many, led on by their rulers and instructors, against the profession of medicine, a strange anomaly in our social system? In which of the duties of good citizenship do we come short? It cannot be pretended that we are cumberers of the ground. Few of our detractors are without personal experience of benefits from our calling. Are we slothful in its exercise? Our path of duty is notoriously an arduous one, trodden with toil and anxiety, and environed by dangers at every step. Are we self-seekers? Zealous labourers in our ranks have directed, and continue to direct their energies to the discovery and dissemination of the knowledge of means by which certain diseases may be prevented, and the process of cure in others simplified and abridged, and *pari passu* the necessity for our services diminished. The progress of medical discovery in the present age is, in fact, chiefly in these directions; yet the voice of no Demetrius has been heard amongst us, inciting to resistance of innovations so directly hostile to "the craft by which we have our wealth". How comes it, then, that, to borrow your own words, "medicine is of all professions, trades, and callings, the one most grievously contemned"; that wits, great and small, unceasingly pelt us with their "paper pellets of the brain"; that grave men open their mouths regarding us only to talk us down; that the legislator shrugs his shoulders often before he can be brought to listen to our appeals for the redress of old grievances, but manifests no indisposition to saddle us with new burdens; that hospital boards and other public bodies make us their unpaid drudges and their toad-eaters?

A little self-examination will, I apprehend, go far to enable us to account for our helpless position in society. The natural bond of brotherhood is feeble amongst us; and implacable feuds and unseemly jealousies take its place. Hence it is that wrong and contumely, which would never be offered to a well-organized body, or would fall harmless if offered, unsparingly assail us. Our undisciplined ranks can offer no effectual resistance to the enemy.

The public estimate of medicine, moreover, is unthinkingly and unjustly made up from observation of the discreditable doings of individual members of the profession—doings which, although heartily repudiated by the great bulk of us individually, is allowed to pass without rebuke from us as a profession. Dr. A. offers himself cheap, in order to supplant Dr. B., who rates himself higher; Dr. C. openly assails or backbites Dr. D., hoping to take more by damaging the reputation of his rival than by labouring to build up and sustain one for himself; Dr. E., perceiving that the lying pretensions of the quack have a higher money value than the conscientious efforts of the regular practitioner, disencumbers himself of his first love, and humbugs, after the most approved fashion, for a better livelihood. Others adopt a middle course, and mingle charlatanic tricks with professional practice. The general public witness these unworthy struggles for advancement, and, without reflecting that the offenders against good manners and morals are not the entire body of the profession, or that many of its worthier members are merely disgusted spectators, place, as I have said, the misdeeds of the few to the account of the many. Hence has arisen much of the obloquy which has become the unmerited "badge of all our tribe".

Is our condition hopeless? No! but it is chronic, and cannot be shaken off in a day. One leading indication of cure, however, may be expressed in the single word *UNITE*. Banded and knit closely together by a common tie, we should at no distant period succeed in establishing a higher internal standard of morality, and a larger measure of respect from without. The

most powerful instrument wherewith to accomplish these ends shall be found, I believe, in our ASSOCIATION, if its sphere of action be sufficiently extended. To every British practitioner of medicine not yet a member of this our league, I would say, COME OVER TO US. Let our combined influence spread—let our Branches (affluent and efferent as regards the parent centre) be distributed over the length and breadth of the land, until membership, involving subjection to the control of a suitable code of ethics, shall become an indispensable token and guardian of respectability, sought after by every medical man within these kingdoms. Thus protected from ourselves, and presenting a compact front to the common enemy, our rights would be secure.

I am, etc.,

R. TURNER, M.D.

Kaith, Banffshire, June 1, 1853.

THE RESPECTABILITY OF THE MEDICAL PRESS.

LETTER TO THE EDITOR FROM TYLER SMITH, M.D.

SIR,—In the notice of the annual dinner of the medical officers of the army, on the 21st ult., you refer to the circumstance of the names of Dr. Cormack, Dr. Semple, and myself, having been given with the toast of the Metropolitan Medical Press; and you observe: "Dr. Tyler Smith remarked, that his connexion with journalism belonged more to the past than to the present: and Dr. Semple stated, that he was only an interim editor—that he had no wish to be anything else; for he thought there were other professional occupations less responsible and more respectable."

It has been supposed, from this, that I joined with Dr. Semple in turning my back upon the medical press, and speaking of it in derogatory terms. Nothing could be more repugnant to my feelings; and, to remove any such impression, I beg to forward what I really did say on the occasion in question. I certainly know of no occupation in the profession which is either more "respectable" or more "responsible" than that of the upright medical journalist.

I am, etc.,

W. TYLER SMITH.

7, Upper Grosvenor Street, June 18th, 1853.

"I feel it an honour that my name should have been associated with the toast of 'The Medical Press of London,' by the chairman (Mr. Guthrie), a gentleman not less distinguished in the literature of the profession than in the practice of civil and military surgery. My own connexion with the medical press belongs rather to the past than to the present; but I shall ever remember with pride that many of the best years of my life have been devoted to a field of labour so useful and honourable. Speaking as I do in the presence of the Presidents of the Colleges of Physicians and Surgeons, I feel that I cannot, like those gentlemen, appeal to the antiquity of the institution I represent. The medical press is emphatically a new power; but it has already proved itself not the least of the powers of the profession. Only yesterday, as it were, the medical press was almost entirely occupied in discussing the symptoms of this or that disease, and the doses and effects of this or that medicine. Such is not, in my opinion, the highest vocation of the press. Its nobler objects are the discussion of the condition of the medical body politic, and the formation and expression of public and professional opinion on every topic relating to the rank of medical science, and the welfare of its followers. At the present time, able men connected with the medical press pursue these objects with such zeal and integrity, that no delusion can long pass undetected, no imposture unexposed, and I will add, no wrong unredressed. It is thus that the medical press must become more powerful than Halls or Colleges in uniting the whole profession as one body, and in urging medicine onwards to that rank in the state to which she is justly entitled. Sir De Laey Evans has said that, in his successful effort to obtain the military honours of the Bath for distinguished military and naval surgeons, he acted chiefly as a channel for conveying information between the advocates of this great concession and the government. It is within my knowledge, that the same pens which supplied the gallant general with the data upon which he proceeded, also argued the question continuously in the medical press. The press can never be employed more nobly than in promoting the spirit of union among the entire profession. Only a few years ago, those who followed the military and naval departments of medicine were as widely divided from civil practitioners as though they had belonged to some different calling. It is now far otherwise; and I believe that no injury could be inflicted upon a naval or military surgeon in

any part of the world, without exciting the ready sympathy and support of the civil branches of the profession; and I am sure that, in the prosecution of any just object, naval and military surgeons may count upon the aid of their brethren of all grades. I say it with pride, but I do not think that such a change as this could have been effected without the existence of a medical press."

[Our report (June 3rd, p. 496), so far as it goes, tallies with that now supplied by Dr. Tyler Smith. The medical press is, as a whole, as respectable as the press of any other class or profession. Yet how common is it for medical men anxiously to disavow all connexion with medical journals, from the dread of being associated in the public mind with what is bad, and not with what is good in them. Let us hope that better days are coming. EDITOR.]

THE GOVERNMENT AND THE MEDICAL BILL.

LETTER FROM P. C. DE LA GARDE, ESQ., TO THE EDITOR.

SIR,—A leading article in the ASSOCIATION JOURNAL of the 6th of May, under the head of "The Medical Reform Bill", contains the following paragraph:—"Lord Palmerston, it appears, has hitherto found his hands so fully occupied, that he has not had time to take up the Bill; nor is it probable, considering the overburdened state of the Commons' House of Parliament, that the Bill, if introduced there late in the Session, would pass into law. Under these circumstances, Mr. Hastings (who is in constant communication with the rest of the Committee) has thought it best to make an effort to introduce the Bill into the House of Lords. We believe that arrangements with that object are being made for a deputation to wait on Lord Aberdeen on an early day, probably on Thursday, the 12th."

Accordingly, on that day, and for that purpose, a deputation from the Provincial Medical and Surgical Association waited on Lord Aberdeen, at his official residence. From the report of its JOURNAL, I collect that an address was read to his Lordship by Sir Charles Hastings, containing this passage:—"We earnestly request your Lordship to enable it (the Bill) to pass into law during this Session of Parliament, in order to stop the agitation which will otherwise assuredly continue."

Several speakers then addressed Lord Aberdeen. Amongst them was Mr. Wakley, who said:—"He trusted that Lord Aberdeen would introduce it into the House of Lords, it being a question eminently fitted for their consideration."

Lord Aberdeen is reported to have replied:—"That he should be most happy to afford them every facility in his power; and, unless some unforeseen obstacles should arise, he hoped to be able to carry out their wishes."

This expression, combined with your admission, that there was little or no prospect of Lord Palmerston's introducing the Bill, and the confident tone in which the JOURNAL continued to call for agitation on behalf of a Bill supposed to be in progress, led myself, no less than others, to the inference—as natural as it was general—that the Bill had been transferred from Lord Palmerston's care to that of Lord Aberdeen.

LORD ABERDEEN HAS NOT TAKEN CHARGE OF THE BILL, *supposed to be contemplated by the Government.*

I beg you will publish this letter to correct a *misapprehension*, which might otherwise lead to inconvenience.

I am, etc.,

P. C. DE LA GARDE.

Exeter, June 8th, 1853.

[The JOURNAL has always correctly chronicled the progress of events. In calling for exertion on behalf of principles to which the Association has long been pledged, it simply discharged an obvious duty. EDITOR.]

LORD LYTTTELTON'S VACCINATION BILL.

LETTER FROM EDWARD BARBER, ESQ., TO THE EDITOR.

SIR,—Lord Lyttelton's Vaccination Bill appears to be in many points very objectionable, and calculated rather to increase than allay prejudices against vaccination. By section i, provision is directed to be made for "affording increased facilities for the vaccination of the poor"; and it is further directed that the lymph used shall be taken "from the arm of a healthy child then present". Section ii includes every child born in England and Wales; and insists upon vaccination within three months after birth. Section iv requires that, in every case of vaccination, a child for vaccination, a medical certificate of such nature as to be given every two months until the child is vaccinated, allows no other legal ground for delay.

It seems hardly to come within the province of the legislature to prescribe the mode of performing vaccination. Some prefer recent lymph on points to fluid lymph, thinking it less likely to be washed away by the flow of blood from the puncture. Others prefer fluid lymph. Surely it may be left to each practitioner to pursue his own plan so long as efficient vaccination is secured. As well might an act be passed, to provide that all teeth shall be extracted with forceps, as to make the use of fluid lymph obligatory.

To limit the period for vaccination to three months after birth is not wise. We know that very young children often escape epidemic and contagious diseases, which attack others around them who are rather farther advanced in life; tender age apparently rendering persons less susceptible of the influence of morbid poisons. On this account some practitioners prefer to vaccinate children after rather than before they are six months old, thinking that during the period of comparative insusceptibility (the few earlier months of existence), the vaccine virus may not possibly produce those constitutional effects which are necessary to secure the child from small-pox, so fully and so effectually as at rather a later period. Another objection to this limitation is, that it enforces vaccination at all seasons of the year. It has appeared to me that, in the cold weather of winter, the vaccine pustule does not go through its stages so regularly as in warmer weather; it is generally slower in its progress; and in very hot weather in summer, there is often an excessive inflammation. I do not assert that it is less effective, but I think this and the preceding objection are worth attention. We know that cold weather is prejudicial to very young as well as to old people; in winter, therefore, it is not desirable in any way to disturb the health of an infant, especially of a very young infant. If much fever follow the vaccination, the liability to mischief from cold is of course greater than in milder weather. Moreover, it is not possible in the country to get vaccine at all seasons; and a constant supply cannot be kept up in any but very populous neighbourhoods. To insist, therefore, upon the vaccination of every child within three months of its birth, will render it almost impossible to comply with the requirements of section 1, to use fluid lymph. Fresh supplies of dry lymph must be constantly obtained from London or elsewhere; and it will be rare that a country practitioner will be able to know anything of the child from whom it is taken. Those only who know the prejudices and apprehensions of mothers on this point can know how much inconvenience and dissatisfaction will often result from this. I believe the general custom in country districts to be, that in the early spring, and again towards autumn, a supply of vaccine lymph is obtained, and all children fit for and requiring vaccination are then attended to: the supply being kept up by the several practitioners until there is no more need of it.

The repeated certificates required in cases of unfitness will give rise to much trouble, and, in many instances, to much expense to the public. In the country, and in winter especially, an infant cannot be taken several miles from home; a journey must therefore be made by a practitioner every two months to see the child and report it; and in the case of a small farmer, a village shop-keeper, and a labourer just above parish relief, it seems hardly right to impose upon them such an expense and trouble, without any compensating advantage either to them or to the public. These are practical details, of which members of the legislature are evidently not cognizant; but without some knowledge and recognition of them it is impossible to frame any satisfactory arrangement.

The stringency of Lord Lyttelton's bill is enough to defeat its purpose. It unnecessarily interferes with, and too arbitrarily directs, duties and arrangements which had better be left in some measure to the convenience and discretion of the public and the profession. Its requirements are such that they must of necessity be constantly evaded, especially in rural districts.

But it is not in these details only that the bill is objectionable. His Lordship seems to have started upon a wrong principle; and he does not touch the root of the evil he proposes to remedy. The chief disseminators of small-pox are the tramps, gipsies, and vagrants of all kinds; and of these some are Scotch, a large number Irish, all of whom are excluded from the operation of the proposed law. These are the offenders, the parties upon whom the powers of the legislature should be brought to bear; not the settled inhabitants of the land, against whom alone the proposed bill seems to be directed. It is true that, in the lower classes especially, much apathy exists; and amongst them, we sometimes meet with strong prejudices against vaccination, which, probably, will not be lessened by too intimate a connexion of it with parish relief and boards of guardians. In

legislating upon the subject, great care must be taken lest prejudice be confirmed and extended, and apathy aroused into opposition, by imprudently attempting coercion, and associating legal penalties with that which ought always to be treated as a boon to all to whom it is offered. I am, etc.,

EDWARD BARBER.

Stamford, June 1853.

ADVICE GRATIS BY "RETIRED PHYSICIANS".

LETTER TO THE EDITOR.

SIR,—In common with those who have the interest of our profession at heart, I warmly thank you for your able articles upon gratuitous advice. While I crave your permission to make a few observations upon a phase of the subject which has not hitherto engaged the attention either of yourself or correspondents, permit me to observe that it is chiefly by anonymous communications that great evils are overcome. The power of the press would be greatly weakened were the writer of every article known; and when we have to attack evils in so jealous a body as the medical profession, it behoves us occasionally to adopt the motto of Junius—*Stat nominis umbrâ*.

I have read in your number of the 3rd instant, a letter by "A SENIOR PHYSICIAN", showing the growth of the system of "advice gratis", and my experience fully justifies him in his remarks. He has, however, not touched on a subject which greatly trenches on the fair and legitimate earnings of the whole profession. I allude to the practice adopted by the quasi-retired members of the profession of prescribing gratuitously for their rich neighbours and friends.

Before I settled in practice, I visited the greater number of the English watering places, and at the various libraries I met men of my own profession, advanced in years, who had retired from the active duties of life, but who, forgetting their own struggles in earlier days, were ready and willing to prescribe gratuitously for their chatting acquaintances and sea-side gossips, without any reference to their means. A friend of mine, in practice in a large watering place, told me that this system was carried on to such an extent, that the profession in that town were robbed of at least a thousand a-year by this unnecessary and canting kindness.

Thus, Mr. Galen, a general practitioner, retires from his arduous practice, purchases an Erlangen diploma, and retires to enjoy the *otium cum dignitate* with the elegant society of Breezytown. He calls upon the native doctors, and thus addresses them—"I have been thirty years in practice, my dear sirs; it is time I should retire. I have taken a house in Nobbyton Square, and mean to enjoy myself." Invitations to dinner follow, and the professional gentlemen of the town introduce Dr. Galen to their friends. The house is furnished, the door painted, when lo! a large brazen plate is engrafted bearing the name of "Doctor Galen"—the retired physician.

Thus steps Dr. Galen into society. After his quiet dinner, or rubber, he prescribes for his kind entertainers, purely as a "friend". He soon becomes overwhelmed with invitations, and ladies' ailments; and thus, without benefiting himself one penny, he poaches upon the manors of his neighbours, and daily robs the profession which has showered her choicest gifts upon him!

Sincerely do I long for the registration of the profession, that we, the advancing members, may know our retiring friends. Your correspondent expresses the truth when he says, "it is useless to complain, until we can act together as an undivided body. Class interests warring with each other are the cause of all the many evils which afflict the profession." But how can we check the evil of which I now complain? It has been said that the physician gets no bread until his teeth are too old to eat it. What chance, I ask, has he in the present state of things, if each year brings men of established reputation into his field of exertion, ostensibly to retire, but actually to rob the profession. I very much doubt if medical men ever do retire. When they do, and act in the manner I have now sketched, they do more to lower the professional services of the physician in the estimation of the public, than any other of the evils so justly complained of by yourself and correspondents.

I quote on this head the following passage from *The Moral Aspects of Medical Life*, by my late and much-lamented friend and fellow associate, Dr. Mackness, of Hastings:—"There is one trait in the character of Hallé which, however much we may admire the spirit which prompted it, we cannot approve, and that is his reluctance to receive fees, even from those who could well afford to pay. It is true that his ample fortune might

be sufficient to supply all the wants of his family; and therefore such a line of conduct was attended with no great sacrifice, while to his benevolent mind it doubtless afforded him the purest enjoyment. But did none others suffer from such a line of conduct? Was the medical profession so affluent in his day in Paris that there were no men of energy and talent belonging to it who, without property, without friends, felt their spirits broken, their hearts sickened from want of professional success? Such is too often the case in England, and doubtless the same in France. And if a man of Hallé's talents and acquirements refused to be remunerated for his professional skill, did it not limit the field for their exertions, and this without doing good to himself? Dr. Percival, in his *Medical Ethics*, says most distinctly on this point: "A wealthy physician should not give advice *gratis* to the affluent, because it is an injury to his professional brethren. The office of physician can never be supported but as a lucrative one, and it is defrauding in some degree the common funds for its support, when fees are dispensed with which might justly be claimed."

Let a higher tone of feeling actuate us in every step of our career; let us regard each other as fellow-labourers and fellow-strivers, not only for the world's good opinion, but for mutual respect and esteem; let us put aside class distinctions, class laws, and class interests; and then, when taking to ourselves our legitimate grades, without repudiating the knowledge of our neighbour, let us act together with united will. For depend upon it, so long as the public recognize the distinction of physician and general practitioner, so long will they act fairly to both. It is only when we forget what is due to ourselves, that the public takes advantage of our want of unity.

I am, etc., A JUNIOR PHYSICIAN.

June 5th, 1853.

PHYSICIANS AND GENERAL PRACTITIONERS.

LETTER FROM J. C. BLOXAM, ESQ., TO THE EDITOR.

SIR,—Surely the letter published in the number of the ASSOCIATION MEDICAL JOURNAL, for June 3rd, by a "Senior Physician" is written in a most unreasonable spirit. No doubt the physician has a perfect right to give "advice gratis", if he choose so to do; but it strikes me as at least equally clear, that the general practitioner is under no obligation to find employment for the physician. The Senior Physician seems not only to be of opinion, that the general practitioner is incompetent for the practice of medicine without the assistance of a physician, but he apparently considers it to be incumbent on society at large, and distinctly intimates it to be the "duty" of the general practitioner to view the matter in the same light. This must be a very mistaken notion. No doubt the time was, when the apothecary was *not* competent to the practice of medicine, and it was a mistake perhaps to allow him to practise in that way; but this does not at all warrant the notion that the "highly educated" general practitioner of the present day is not fully as competent to practise as the physician. No doubt many physicians may be found, who are far more competent than are a great number of the general practitioners; but I have no doubt that many general practitioners may also be found, who are more competent than many physicians. I see nothing but prejudice, that should induce society to regard the physician as in practice superior to the general practitioner.

It should be borne in mind by physicians who complain of not being consulted more frequently by the general practitioner, that if a general practitioner calls in another member of the profession of higher rank than himself in consultation, he is clearly in danger of giving encouragement to the idea that the higher rank is accompanied with superior professional qualifications; whilst, if he calls in another of equal, or inferior rank, he is not in the same danger of being understood to acknowledge a superiority which he does not feel.

When a man determines upon practising as a physician rather than as a general practitioner, I apprehend that he does so for the sake of the higher rank and greater dignity that he enjoys thereby. But if a greater number of men offer their services to society in this capacity than society or the highly educated licentiates of the Apothecaries' Company feel it their interest or duty to employ in that capacity, they surely ought not to complain either of society or of the licentiates for not conferring on them the profits as well as the dignity. Looking at the matter in this point of view, I think that the general practitioners are fully as much to blame as the physicians. The general practitioners are the practitioners generally employed; and having got into their hands that business which formerly

belonged to the physicians (I think it can scarcely be said now more legitimately to belong to them), viz., the treatment of disease, they are not content with the profit accruing therefrom, but are dissatisfied with the relative rank and dignity of the two parties. Having deprived their neighbour of the profits, they seem unwilling to allow him to enjoy the rank and dignity of doctor. Now this is wrong in more ways than one; for the physician of this country, as a general rule, has qualities in him beyond those of the general practitioner for obtaining the respect and esteem of society; and this is not to be considered, through the contrast, an injury to the general practitioner. On the contrary, the respect and esteem thus acquired, is acquired for the benefit of the profession at large.

Whilst the general practitioners appear to err in this respect as regards the physicians, they appear to me to err also in other directions. They show a disinclination to practise that branch of their business which especially belongs to them, viz., the dispensing of medicines. Now it is by the dispensing of medicines that they have acquired their present advantages over the physicians; but whilst they feel themselves justified in having done this, they deem it very wrong that the druggist should play the same game. The public, however, will assuredly consult those who will dispense the remedies to be used. In the same proportion as the general practitioners contract their practice of dispensing, will the druggists expand their practice of prescribing; and it seems doubtful if any *locus standi* will hereafter remain for the apothecary between the accomplished physician and the accommodating druggist.

There are several remarks made in the letter under consideration, which admit, perhaps, of somewhat severe criticism; but I will refer to only one passage, which I object to on the score of false reasoning. The writer advances the practice of solicitors, in order to contrast it with that of apothecaries; but there is no analogy between the cases. The barrister does not rival or compete with the solicitor; far from it, he obtains the *whole* of his business from the solicitor. Let the physician renounce all business but such as is brought to him by the apothecary, instead of entering into competition with him, and there will then be some analogy between the two cases. I am, etc.,

JOHN C. BLOXAM.

Newport, Isle of Wight, June 7th, 1853.

PHYSICIANS AND GENERAL PRACTITIONERS.

LETTER TO THE EDITOR.

SIR,—I fear "A Senior Physician" is a disappointed man; and from the *animus* displayed in his letter, I would not select him to heal a breach between the physicians and the general practitioners. I think he ought not to blame the latter because he is not called in as often as he wishes, or as often as the physician was fifty years ago. He forgets that during that period a great change has taken place in medical education, and that the general practitioner of 1853 is equal, if not superior, to the physician of 1803. Therefore he is not called in, simply because he is not wanted. For this he must not blame the general practitioner, but the course of events. I entirely dissent from him, and *never under any circumstances refuse a consultation*; but I always feel myself at liberty to choose the "second opinion", and even if any one be named, I consider myself justified, if I think proper, in proposing another.

Not long since, the friends of a patient I was attending wished for a second opinion, and mentioned Dr. —; I proposed some other physician and a general practitioner; the latter was chosen, and the patient is recovering.

In fact, there are some physicians whom I never call in unless I am obliged, because in more than one instance they have taken away my patient. Other general practitioners make the same complaint. Do you blame me? If all physicians conduct themselves towards the general practitioners as some of those whom I know do, you must not be surprised if an ill feeling exists between them. Whom would you consider as the *heads* of the profession? Generally speaking, you would say, those who hold the appointments to our infirmaries; yet in this *trip*, more than one infirmarian physician will visit patients four times for a guinea, thus placing themselves on a level with the general practitioner; and one of them vaccinates. Here, I think, the general practitioner has just cause of complaint.

So far am I from being jealous of the physician, that I have no place in England offers a better opening for one than this. Indeed, one is wanted; and I believe that a respectable man settling down here, and going hand in hand with the general practitioners, and not setting himself in opposition

them, could not do other than succeed, if he have patience to wait.

I should not have troubled you with this letter, did not I feel that the fault is not all on one side, as "A Senior Physician" would wish you to suppose. I am, etc.,

A MEMBER OF THE ASSOCIATION, AND A
GENERAL PRACTITIONER.

June 7, 1853.

CASE OF CALCULUS REFERRED TO IN THE REPORT OF THE MEETING OF THE YORKSHIRE BRANCH.

LETTER FROM HENRY JACKSON, ESQ., TO THE EDITOR.

SIR,—In the report of the meeting of the Yorkshire Branch, published in the ASSOCIATION JOURNAL of May 20th, there is an error respecting a calculus which I exhibited. The following is the statement of the case which I read at the meeting:—

"The calculus, weighing 9 oz. 3 drs., was extracted after death from a man aged 32, and had existed from childhood. Operation had been proposed several times both to his parents and to himself, but had been refused until within a fortnight before his death, when he was admitted into the Sheffield Infirmary, to be operated upon. He had taken large doses of opium, for the purpose of alleviating his sufferings, which had been most extreme, and in a paroxysm of which he once attempted his own life and that of his sister. The kidneys presented a granular condition; their secreting portion in some parts being entirely removed, and its place supplied with urinous cysts, many of them containing pus. The bladder was much thickened, and its mucous membrane very coarse. The ureter was very much and irregularly dilated. During life, the urine was of the sp. gr. 1010, albuminous, and deposited large quantities of pus. The patient died from epilepsy, induced by suppression of urine. I am, etc.,

HENRY JACKSON.

St. James Row, Sheffield, May 31st, 1853.

NEWS AND TOPICS OF THE DAY.

INQUEST AT SHEFFIELD:—THE MEANING AND VALUE OF MEDICAL TITLES. Alfred Davis, *alias* Dr. Henry and Co., "a practitioner of a certain kind", described by the *Sheffield Times* as "a dashing young man", had a *liaison* with Mrs. Glossop, his landlady, during her husband's absence in Australia. Mrs. Glossop had a miscarriage, and died soon afterwards. Davis was suspected of having hastened her death by causing abortion, but no proof of this appeared, though strong suspicion existed, as he had absconded on the first rumours of his foul play. After examining medical and other witnesses, the coroner summed up as follows:—"The cause of death, according to the medical evidence, was very clear. It did not appear that anything likely to produce death had been given. She had been recently delivered, but whether by natural means, or artificial, there was no means of ascertaining. It did certainly appear somewhat singular that Mr. Davis, who stated that he was not a licentiate, nor a surgeon, nor a graduate of any university, but simply a vendor of patent medicines, should advertise that "Dr. Henry and Co., surgeons, continue to be consulted, daily, at their establishment, etc."

Mr. Fretson: He styles himself "confidential medical adviser". Now that can only have one meaning. It is perfectly plain what his business is.

The Coroner: I differ with you. A medical man is confidentially consulted whatever may be the nature of the disease. If parties choose to deal with such men, it is their own fault, more than the fault of the self-styled surgeon. I think the evidence of the medical men shows that Mrs. Glossop has died of coma, arising from intense congestion of the brain, and effusion of blood on the surface of the brain, in consequence of having been recently delivered of a fetus, but whether naturally or artificially effected, there is no evidence to show. In consequence of Mr. Davis having left the town, and it being reported in the neighbourhood that the deceased had been poisoned, I thought it necessary to have the body exhumed; but there is nothing in the evidence to implicate Mr. Davis.

The room was then cleared, and after the coroner and jury had been alone together about twenty minutes the doors were again thrown open—when the coroner said that he was desired

by the jury to ask Dr. De Bartolomé whether, having heard the result of Mr. Haywood's analysis, he saw reason to alter his previously expressed opinion of the remote cause of death. Dr. De Bartolomé replied in the negative.

The jury then returned the following verdict. "That Hannah Eliza Glossop died of coma, arising from intense congestion of the brain and effusion of blood upon its surface consequent on her having been recently delivered of a fetus, but whether naturally or by artificial means there is not sufficient evidence to prove." The foreman read the following *addendum*:—"We beg to express a very strong opinion as to the impropriety and levity of conduct not only of Mrs. Simpson and her late daughter, but also of Mr. Davis."

ST. MARY'S HOSPITAL. DINNER. The third anniversary of this institution was celebrated on the 28th May, by a public dinner at the London Tavern. The Earl of Carlisle, who presided on the two former occasions, again filled the chair. He stated that the hospital was opened in June 1851, with 50 beds for in-patients; but in the winter of the same year the number was advanced to 100. In June 1852, the beds were increased to 150. From the opening of the hospital on the 13th of June, 1851, to the 30th of April in the present year, there were treated as in-patients, 2021; as out-patients, 5599; as casualties, 3030; and 447 poor married women were attended in their confinements at their own homes; making a total of 11,067 persons to whom the benefits of the hospital were extended in a year and ten months. The estimated cost of maintaining the hospital, with its 150 beds, and of supplying medicine to the daily increasing out-patients, was £5,500 per annum; but the amount of annual subscriptions received for those purposes in 1852 amounted only to the sum of £1710 : 7 : 6, and he was sorry to add that there remained liabilities to the amount of £2,300 to be provided for. The donations announced during the evening amounted to £1,850.

HOSPITAL FOR CONSUMPTION. DINNER. On Wednesday, the 14th anniversary of this hospital was celebrated at Willis's Rooms, the Marquis of Westminster presiding, supported by Lord Feversham, Lord Dynevor, the Rev. Sir H. Foulis, Bart., and eighty other gentlemen. It was stated that in the year, 443 patients were admitted, of whom 292 were discharged relieved, and 61 died. The out-patients numbered 3671. Since the opening of the hospital 2,445 in-patients, and 21,441 out-patients have been treated.

NEW HOSPITAL FOR CHILDREN IN PARIS. The Empress of the French has expressed a wish that a second hospital for sick children should be erected in the Faubourg St. Antoine, a very populous eastern district of Paris. The present hospital for children is situated in the Rue de Sévres, at the south-western extremity of the town, and contains 626 beds. The new institution is to be constructed near the St. Antoine Hospital, and is to start with 200 beds.

TESTIMONIAL TO MR. D. HARTLEY. Some of the members of the Board of Governors of the Cheltenham General Hospital, and their friends, have presented to David Hartley, Esq., the house-surgeon, a chaste and handsome silver salver, with the following inscription:—"To David Hartley, Esq., house-surgeon and honorary secretary to the Cheltenham General Hospital, presented as a slight token of their personal regard, by the members of the Quarterly Board of Governors and their friends, who have for many years had the pleasure of witnessing the ability, kindness, and attention with which he has discharged his important duties, as well towards the poor as for the benefit and general interests of the Hospital. March, 1853."

THE CHOBHAM ENCAMPMENT. A singular omission has taken place at the Camp on Cattenham Hill, where, although there are 200 men under canvass, there was not, up to this week, a single medical man or surgeon, or even one within four miles; and this, although "the Queen's regulations and orders for the army", according to the 40th section, page 273, provides, that wherever a body of men amounting to 200 is encamped, a surgeon or assistant-surgeon belonging to the commanding officer's corps, shall be in attendance. Such an oversight as the one alluded to reflects very little credit on the parties to whom were committed the arrangements of this section of the encampment.

M. CLOQUET. The Emperor of the French has conferred the rank of officer of the Legion of Honour on M. Cloquet, physician to the Shah of Persia, and nephew to the Professor of the Faculty of the same name.

MR. TOYNBEE, F.R.S. At the general meeting of the Society of Arts, held on Friday June 10th, His Royal Highness Prince Albert, president, in the chair, the Society's Medal was awarded to Mr. Toynbee, F.R.S., aural surgeon to St. Mary's Hospital, for his invention of "the artificial membrana tympani in cases of deafness, dependent upon perforation or destruction of the natural organ".

THE ANNUAL INSANITY PRIZE. The prize for the best Essay on the subject of Insanity, offered by the Society for Improving the Condition of the Insane, has this year been awarded to Dr. D. H. Tukey, of York. The subject for competition was "The Progress of the Treatment of the Insane since the time of Pinel; and the Contrivances which have been adopted in lieu of Mechanical Restraint".

THE NEW HOSPITAL AT CALCUTTA is in connexion with the Medical School. It contains five hundred beds; and is divided into twenty-four spacious, cheerful, and well ventilated wards. One wing of the hospital is appropriated to the diseases of women and children.

THE QUEEN AND THE LATE NURSE OF THE ROYAL INFANT. Mrs. Mackintosh, who was appointed wet-nurse to the Royal Infant, has returned to the north. It appears that her milk was too rich for the infant Prince—so much so, that her own child was also nursed by her for some time, in order to reduce the quantity. Mrs. Mackintosh left Osborne amidst the regrets of the whole establishment, expressed in the strongest terms, and accompanied by substantial proofs of the Queen's liberality. Her Majesty presented her with a valuable gold brooch, an ample wardrobe of clothes, and a check for a hundred pounds—all this being exclusive of travelling expenses. The brooch was given by the Queen with her own hand, and will, we have no doubt, be treasured for generations as an heir-loom of inestimable value.—*Inverness Courier*.

JUSTICE TO SCOTLAND. A Scottish periodical, in pleading for "Justice to Scotland", thus contrasts the favours lavished on "turbulent and indolent Ireland" with the opposite treatment which "peaceable and industrious" Scotland receives at the hands of Government. Perhaps, after all, grants from the National Treasury, by removing excitements to exertion, are sources of injury and not of benefit; and had Ireland been less petted, she might have been more prosperous.

"The Church. Ireland has an established religion, and so has Scotland—but except an insignificant trifle to the Episcopal body, no dissenting community in Scotland receives one farthing of public money; whereas, the Roman Catholics, the Presbyterians, and the Unitarians, all receive subsidies in Ireland.

"Education. The national schools in Ireland have been defrayed out of the imperial purse. Scotland has no corresponding national schools. Within the last ten years three colleges have been built and endowed in Ireland. Since the Union, Government has neither built nor endowed a College in Scotland. The State supports Trinity College for the Established Church in Ireland, Maynooth for the Catholics, and the Belfast Academical Institution for the Presbyterians and Unitarians. Scotland receives a pittance for its five universities, but the total amount does not greatly exceed what is given to Maynooth alone.

"Benevolent Institutions of Dublin. We have already stated that in such matters Ireland is entitled to peculiar treatment, and we have no wish to retract our concessions on this point. When famine or any extraordinary crisis occurs, we are willing to extend generous sympathy to the Irish, and to aid in extricating them from their difficulties with no niggard hand; but when we come to put Dublin against Edinburgh, we can perceive no just reason for exceptional allowances. The capital of Ireland is every whit as wealthy, and its trade as flourishing, as that of the capital of Scotland; it has, hitherto, been exempted from income-tax, and enjoyed other immunities to which Edinburgh has been a stranger, and there is nothing to prevent Dublin from putting its hand into its own pockets and supporting its sick and hurt exactly as Edinburgh does. But how stands the fact? Here are the grants to Dublin for one year:—

Foundling Hospital	£ 650
House of Industry	9,883
Westmoreland Lock Hospital	1,750
Female Orphan Hospital	600
Fever Hospital	3,040
Lying-in-Hospital	600
Dr. Steeven's Hospital	1,200
Hospital for Incurables	400

£ 18,123

"There are in Edinburgh a Royal Infirmary, several dispensaries, ragged schools, and fever and lying-in hospitals, not one of which receives contributions from the public purse. But we are sick of these comparisons, and will carry them no farther—to do so were a work of supererogation—they speak for themselves in a language that cannot be misunderstood by enlightened and impartial men."

NAVAL ASSISTANT-SURGEONS. A petition to the House of Commons from the members of the medical profession, complaining of the imperfect compliance of the Admiralty with the order of April 1850, and praying for an inquiry into the condition of the Assistant-Surgeons in Her Majesty's Navy, is in course of signature. It is in the charge of Mr. T. M. Stone, of the Royal College of Surgeons. The petition lies at his residence in Greenwich, and information on the subject will be afforded on application to him either at Greenwich, or at the Library of the College. All legally qualified members of the profession are invited to attach their signatures.

REMEDY FOR THE DISEASE OF GRAPES. Payen recommends four ounces of sulphur with an equal quantity of slaked lime to be boiled for fifteen minutes in three pints of water. When cold, the clear liquid is poured off and diluted with fifty pints of water. When the disease appears, the entire vine is to be sprinkled with this solution.

APPOINTMENTS.

[*An asterisk is prefixed to the names of Members of the Association.]

*BEGGIE, James, M.D., appointed Physician in Ordinary to the Queen for Scotland, in room of the late Dr. John Scott.
PAYNE, J. G., Esq., appointed Resident Surgeon to the Millbank Penitentiary.
RENDLE, James G., Esq., appointed Medical Officer of the New Female Convict Prison at Brixton.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were Members of the Association.]

WRIGHT, Samuel, M.D., Physician to the Queen's Hospital, Birmingham, of consumption, aged 34, on May 30th. Dr. Wright was the author of an able treatise on the *Physiology and Pathology of the Saliva*, as well as of other works.

BOOKS RECEIVED.

ADVERTISEMENT.

Marischal College and University,

ABERDEEN—Besides the ordinary Examination Terms, (in April and October,) there will this year be a third, in the last week of July, to meet the case of Candidates for the Assistant-Surgery H.E.I.C.S. offered by Col. Sykes to the best competitor among the students who have completed their academical course at King's or Marischal College; and for the Assistant-Surgery in Her Majesty's Service, offered for competition to the students of Marischal College, by the Director-General of the Army Medical Department.

CASES IN WHICH MEDICAL PRACTITIONERS MAY BE ADMITTED, WITHOUT RESIDENCE, TO EXAMINATION FOR MEDICAL DEGREES.

Practitioners may be admitted, without residence, to Examination for the Degree of M.B., who have held a Diploma or a Licence in Medicine or in Surgery for at least five years, and who produce satisfactory evidence of good moral character, and of having been engaged in practice during that period.

Practitioners may be admitted, without residence, to Examination for the Degree of M.D., who have held a Diploma or a Licence in Medicine or in Surgery for at least ten years, and who produce satisfactory evidence of good moral character, and of having been engaged in practice during that period.

Practitioners who have held for at least three years the Degree of M.B., obtained without residence, may receive the Degree of M.D., upon producing satisfactory evidence of good moral character, and of having been engaged in practice during their possession of the inferior Degree.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XXV.

LONDON: FRIDAY EVENING, JUNE 24, 1853.

NEW SERIES.

GENTLEMEN WISHING TO JOIN THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION ARE REQUESTED TO APPLY TO THE GENERAL SECRETARY, TO THE BRANCH SECRETARIES, OR TO THE EDITOR OF THE JOURNAL. The Annual Subscription is One Guinea. Members receive the Journal free by post.

The ANNUAL MEETING will be held at Swansea on the 10th and 11th of August. Gentlemen who have communications to read to the Meeting are requested to give notice of their intention to the Secretary. Communications will be called for in the order in which the Secretary has received notice from the respective authors. Vide p. 470 of May 27 for various details.

We must remind correspondents that, although they may wish their letters to appear under special signatures, it is absolutely necessary to communicate in confidence their names and addresses to the Editor.

ASSURANCE OFFICES AND SANITARY REFORM.

THE day, it is to be hoped, has passed away, when it was thought sufficient to treat a patient for fever, without inquiring into the *cause* of that fever; to prescribe medicines, and not to examine the state of the drains, and water-closets, and sculleries, and dust-bins, and cesspools, of the house where the fever exists. He who does not make this inquiry is behind the actual state of medical science. He has neither attended to the facts brought forward by sanitary reformers during the last twenty years, nor has he made any attempt in his own practice to test their value. He is content to grope blindly in the dark, shutting his eyes to causes which have been proved to exist, and the truth of which he can constantly examine, if he will take the trouble. And as he attends more to these causes, he finds that convulsions in children, violent inflammatory attacks of the bowels, diarrhoea, obstinate dyspepsia, inflammation of the conjunctiva, loss of nervous power, and various rheumatic and neuralgic affections, are to be traced to the same cause as fever, or erysipelas, or malignant epidemic diseases. Indeed, it would be difficult to say what disease, depending on an impure state of blood, may not be produced by habitually breathing impure air. This cause of disease has of late years become much more formidable. Water-closets are now introduced into almost all houses; and, unless the drains are perfect, and the traps good, they become more or less sources of impure air.

We make these remarks particularly in relation to life assurance. It is difficult to see in what way the assurance offices can make the purity of dwellings a point of inquiry; but it is one of so much importance to them, that, sooner or later, they will become aware of its value, and will find the way to ensure it. If we admit the impurity of the air to be a fruitful cause of disease, it must be highly important to ascertain if those who seek to insure their lives are not habitually subjected to such a cause of disease and death. A man forfeits his insurance, if he goes to reside abroad, as

he may there be exposed to the poison of malaria; but he may go into a new house, which is not properly drained, and die from its poisonous atmosphere, without any caution from an office, to which his life is of great value, that he is subjecting himself to an undue risk. Attention to these points by assurance offices might be of great value in sanitary reform. They would bring before the attention of the most prudent, far-sighted, and intelligent of the people—those, in fact, who insure their lives—the danger of living over cesspools, of having dead wells beneath their houses, of neglecting the state of their drains and traps, of drinking the purest kind of water which passes through lead pipes, or is kept in leaden cisterns. If it is known to be the interest of practical men of business to guard against the danger of these causes of disease, to which those who insure their lives are exposed, and by which the profits of the company are decreased, they will discover the means of doing it. The medical examiners of the assurance offices should take every opportunity of bringing the subject before the attention of the actuaries, secretaries, or directors; and, in order to do this effectually, they must have their own faith in such causes strengthened by a practical acquaintance with the evidence. They must lose no opportunity of tracing diseases to their causes amongst their own patients. “The knowledge and power of man”, said Bacon, “are coincident; for, whilst ignorant of causes, he can produce no effects.”

The great importance to assurance companies of sanitary measures has been ably stated by Professor CHRISTISON of Edinburgh. At the request of the Directors of the Standard Company, he examined the causes of the deaths of those assured during a period of five years. The total number of deaths was two hundred and ninety-seven, and sixty-seven out of these died of fever, malignant cholera, scarlet fever, and other epidemic diseases; and fifty-five of these were from typhus and cholera alone. “These fifty-five”, said Professor Christison, in addressing the directors, “may be considered in a great measure an extra loss; for, in all probability, proper sanitary measures would have prevented them. This is a very important matter for the consideration of all assurance companies; for, contrary to what has been thought by many, typhus and cholera do not seem in all epidemics to attack chiefly the feeble and unsound, so as merely to cut off a little sooner those who would perish at any rate at no distant period by ordinary diseases at large; at least, I find that a very large proportion of deaths from these diseases in the company’s list—no less than seventeen out of twenty deaths from cholera, and nearly the same proportion among those from fever—have occurred among what would undoubtedly be considered by every one as *select* lives. Another serious consideration is, that most deaths from these causes occur early in life, and consequently, in general, very soon after assurance is effected.”

This evidence, from an authority like that of Professor Christison, cannot be too widely diffused. He proves that

it is of the utmost importance to assurance offices that sanitary measures should be carried out, since, in five years, one company lost fifty-five lives from diseases which might in all probability have been prevented by proper sanitary measures; and, as he admits this, we must demur to his opinion, that "there are diseases which no care on the part of directors or their medical referees can foresee and guard against". We repeat, that it is the duty of the directors to consider whether they cannot guard against such sources of loss; and, although it may be difficult, it cannot be a problem impossible of solution by a large number of the acutest practical intellects in this kingdom. The medical referees of assurance offices, who must feel to a certain degree responsible for the duration of the lives they pronounce sound, may, by inquiry and cautioning the assured on these points, make them aware of a danger infinitely worse to them than to the office; and there is no reason why such hints and cautions should not be printed on the examination-papers, and read to the assured. These details, however, we leave to the care of those who are directly interested: our object is the advancement of that branch of our science which prevents disease; and here the interests of science and of business coincide.

SUNDAY—AT HOME, OR ABROAD?

IN a subsequent page will be found a letter from a member of the ASSOCIATION, (Dr. Stewart of the Middlesex Hospital,) announcing that six hundred and forty London medical practitioners have signed a petition to Parliament against granting to the proprietors of the new Crystal Palace at Sydenham, the power of opening it for profit on Sundays. Upon inquiry, we find that among the six hundred and forty signatures, there are the names of many of the most eminent, of our profession. The step which has thus been taken by so numerous and influential a body of metropolitan physicians, surgeons, and general practitioners, undoubtedly claims the attention of the journalist. We might perhaps avoid the question, by declaring that it is not professional in its character; and that medical men have nothing to do with state politics; but such a course would not only be opposed to our own convictions of duty, but would likewise be a deliberate censure upon our esteemed colleague Dr. Stewart, and his coadjutors in the present movement. We would not willingly incur such a reproach. Most cordially do we say with Dr. Stewart:—"Woe worth the day, when the lips of the medical man shall refuse to utter that noble sentiment—*Homo sum, nihil humani à me alienum puto*." It is nothing short of professional cant and social heresy to abdicate the responsibilities and the prerogatives of the man, when we assume the functions of the medical practitioner. In becoming members of a profession, we cannot guiltlessly ignore the fact, that we still remain members of the commonwealth; and that while our position as medical men imposes upon us certain special duties, it does not release us from any of the obligations which every citizen owes to the state.

There is a depth and a magnitude in the question before us, which is not sufficiently recognised by many of those with whom we are in the habit of associating and conversing. The question is not merely, Shall the Crystal Palace be open or closed on Sundays? It is the broader question, whether Sunday is to be made in this country—what it has long been

in France—a day of increased toil to the minority, that the majority above them in the social scale may seek pleasures at a distance from their homes, or amid scenes more brilliant and more exciting than the domestic circle? This is the real aspect of the question at issue. Were Parliament to grant to the proprietors of the Crystal Palace the privilege of throwing it open on Sundays to the myriads of this huge metropolis, for gain, assuredly the speculators of Vauxhall and Cremorne, and the lessees of the theatres, would clamorously demand, and ere long obtain, a similar concession. Then, again, in accordance with an universal law, the example of London would be imitated in every provincial town in the kingdom. In this way a rapid and a radical change would be induced in the habits of the people—a change for the better, we shall be told by some of our prominent statesmen and popular orators—a change for the worse, we shall be as positively assured by politicians of another stamp. We can fancy that we see before our eyes the familiar speeches of Mr. Joseph Hume and others in behalf of Sunday amusements for the people—"intellectual and elevating recreations, calculated to entice the toil-worn mechanic from his tavern debaucheries": or, sailing back over the ocean of Parliamentary debate, we can stop at a memorable speech delivered during the discussion on the "Public Houses Bill", on the 1st of June, 1842, by an able statesman, at present a cabinet minister of the Queen. Upon the occasion referred to, Sir James Graham said:—

"I see no evil in a hard-working man taking a little refreshment more stimulating than tea, perhaps, in a public house on a Sabbath morning; and I have been told that in the manufacturing districts it was customary for the artisans to take their breakfasts on such occasions in public-houses, that they might enjoy a little more comfort than ordinary."

We believe that both Sir James Graham and Mr. Hume have a higher object in view than the speaking of pleasant things to ten-pound voters—the aristocracy of the working-classes; and that they sincerely desire to improve society by affording facilities for Sunday extradomestic indulgences and amusements. But while we accord to them all praise for honest philanthropy of purpose, we venture to charge them with a great political blunder. All history proclaims their panacea to be worthless. We cannot help stating our deep conviction that it is shallow statesmanship—charlatanic treatment of the body politic. It is palliating symptoms by soothing syrups, and at the same time allowing the diseased condition, whence the pains arise, to remain without remedy and ready on any slight provocation to burst forth with implacable violence.

Amusement is essential to all classes of the community—to those who work with the mind as well as to those who work with the body: and we would go all lengths with Mr. Hume in earnestly striving to obtain for our toil-worn population a weekly holiday. But we would take the ground of the petitioners, and not purchase this boon at the price of weakening home attractions, and of seducing the heads of families from the cultivation of home affections, amid which only can be acquired enduring lessons of virtue, patriotism, and religion. It is because we believe virtuous homes to be the nurseries of patriots, that we wish to maintain Sunday as a domestic day. Times are fast coming, in which much patriotism is certain to be wanted; and it is, therefore, well for us jealously to refrain from weakening the relish for the purifying pleasures of domestic life, whether by such reckless suggestions as those which fell

from the lips of Sir James Graham, or by systematically enticing people to career over the wide world in search of amusement, on the only day in the seven which gives to the majority an opportunity of family converse.

This is not the place for a discussion upon the theological aspects of the Sabbath question; but, nevertheless, we may be allowed to guard ourselves from misapprehension, by declaring that our convictions are opposed to the puritanical austerities of Sabbath observance. We have adverted to the subject, because there appeared to be imposed upon us the duty of adding our voice to the protest of our medical brethren. With them we feel that the introduction of public amusements on Sunday would be a tremendous stride towards national demoralisation; inasmuch as it would be the commencement of a system which would generate anti-domestic influences similar to those which have been produced in France, and which have formed within the Parisian vortex the most dangerous populace in the world—a populace giddy and improvident—governable only by the physical supremacy of an ever present army. If there be any reader who has thoughtlessly admired the glitter and seeming joyousness of a Sunday in Paris, we would ask him to read the bloody chronicles of the guillotine and the barricade; and to ponder well the fact, that one third of the gay crowd by which he had been charmed are destined to die in the hospitals.*

THE IRISH MEDICAL ASSOCIATION.

It is with the highest satisfaction that we announce that an Irish Medical Association was formed at Dublin, on the 7th of this month, upon the model of our own institution.

The Branch System has been adopted. And a representative government has been constituted, the executive Council being chosen by the County Branches. The following is the excellent rule to which we refer:—

"4. *Council.* That the council shall consist of the president, chairman of the council, four vice-presidents, thirty-two provincial, two general secretaries, and treasurer of the Association, along with sixty-four provincial delegates, two being selected by each County Association annually from its members; seven to constitute a quorum for the transaction of business. With the council must rest the responsibility of managing and conducting the affairs of the Association from one annual meeting to another; the place and time of their meetings to be arranged by themselves.

The Irish Medical Association holds out to us the hand of fellowship; and let us grasp it right heartily, and bid the sister Association God speed. We have no doubt that, when our laws are revised, the Irish Medical Association will be recognised in the same friendly spirit in which the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION is mentioned in the subjoined law.

"10. *Ad eundem Members.* In order to form a union with our English medical friends, that the members of the Provincial Medical and Surgical Association of England, and so certified by their president and secretary, may be enrolled without the payment of any subscription or fee, *ad eundem* members of the Irish Medical Association."

It is worthy of notice, that the name originally proposed was the Provincial Medical and Surgical Association of Ireland; but, ultimately, the more catholic and more compact designation, "The Irish Medical Association" has been selected.

* "The Paris Hospitals are the ordinary asylums of the poor when sick. Indeed, one-third of the population of that city die under their roofs."—Dr. HENRY BENNET in *Inflammation of the Uterus*, p. 447. Third Edition, 1853.

ORIGINAL COMMUNICATIONS.

TWO CASES OF SUDDEN DEATH FROM HÆMORRHAGE FROM ULCERATION OF THE AORTA.*

By CHARLES COWDELL, M.D.Lond., Physician to the Dorset County Hospital.

(Read before the Dorset Branch of the Provincial Medical and Surgical Association, on May 31, 1853.)

CASE I. George Cockerell, labourer, aged 37, admitted June 27th, 1852, stated that he had always enjoyed good health until June 1851, when, after a hard day's mowing, he was suddenly seized with rheumatism, from which, however, he thoroughly recovered. He had since been in the hospital at Salisbury, where he was cupped and blistered on his loins, which were then the seat of much pain. On examination when admitted, he was found to be moderately fat, but flabby; and, indeed, in a state of general cachexia. The sound on percussion over the apices of the lungs was good; respiration was tolerably free, with somewhat prolonged expiration; sonorous and sibilant rhonchi were present in both bases posteriorly, and some finer subcrepitant rhonchus in the left base. He complained still of much pain in his loins. He had some cough, with slight expectoration of thick mucus. He had never spat blood. There was slight aortic regurgitation and constriction: no hypertrophy.

The treatment was directed to the bronchitic symptoms. He took with advantage a mixture containing chlorate of potass, compound tincture of camphor, and tincture of squills, with wine of ipecacuanha, and an expectorant pill at bed-time. Under this treatment, his cough and lumbar pains abated; but he was always listless and inactive. In this way he went on for about a month, when he began to expectorate a little blood mixed with the mucous sputa, and it was thought probable that there was latent phthisis, notwithstanding the slight indications of pulmonary disorder. He was accordingly directed to apply leeches to the chest, and to take oleum jecoris aselli. There was no indication of aneurism.

July 27th. When sitting on a bench in the garden this evening, he coughed slightly, was immediately deluged with blood, and died in a few minutes.

EXAMINATION OF THE BODY. The organs in the chest were found tolerably healthy, except the heart and aorta. Slight aortic disease, affecting the sigmoid valves, and diminishing the aortic orifice, was discovered. Patches of incipient atheroma were diffused over the inner surface of the aorta throughout. In the middle of one of these patches of atheroma was an ulcer, extending through the coats of the artery into the right bronchus. There was no dilatation of the artery; but between it and the bronchus there was a very small sac, formed by the outer coat of the vessel.

CASE II. George Whittle, aged 30, married, a labourer, was admitted at the end of August 1852. He had always enjoyed good health (except an attack of scarlet fever, four or five years previously) until eight weeks before admission, when, after getting wet through while ploughing, he was seized with pain in the left leg, which gradually increased. Of the progressive history of his illness he could give no account, having, as he said, been too ill to remember anything about it.

When he was admitted, the face was worn and pale; there was great emaciation of the upper extremities. The right shoulder could not be moved without great suffering; indeed, he could with difficulty be carried to his bed, or turned when in it. The legs were oedematous, especially the left; as were also the walls of the abdomen, which pitted under pressure. The heart's apex beat between the

* Reported by W. G. Bacot, Esq., House-Surgeon. The meeting at which this paper was read was held at Bridport, Dorset; S. S. Cory, Esq., President, in the chair. The paper was illustrated with pathological preparations of the diseased parts.

fourth and fifth ribs, just under the nipple. The sounds at the apex were very indistinct, though a low soft murmur could be caught; at the base, a distinct rubbing to and fro sound was heard. The heart's dulness appeared to extend towards the costo-clavicular articulation. The pulse was 104, and thready.

In the lungs, percussion was decidedly duller under the left clavicle than under the right. There were strong sibilant and sonorous rhonchi on both sides of the chest; mostly on the right side, where, in the clavicular region, the respiration was loud and blowing, and equal in length to the inspiration. On the left side, the expiration was prolonged, but not nearly as much so as on the right.

Over the front of the abdomen, there was a rash of a blueish shade, disappearing under pressure; the patches varying in size from that of a fourpenny piece to a pin's head.

The bowels were open; the appetite was good.

The following treatment was followed. A blister was applied over the heart, and the following mixture prescribed:—

R Potassæ nitratis ʒij.
Vini ipecacuanhæ ʒij.
Spiritus ætheris nitrosi,
Tinct. camphoræ compos., aa ʒss.
Oxymellis scillæ ʒi.
Aque ad ʒxvj. M.

Sumat cochlearia ij ampla 4tâ quâqua horâ.

September 3rd. He was much improved, though the legs, especially the left, were much swollen. The urine was moderate in quantity, and deposited phosphates.

He gradually improved from this time, so as to be able in two or three weeks to leave his bed, and walk about on crutches, and even to go into the garden to smoke his pipe when the sun shone; but he continued weak and cachectic, with a dejected air and expression.

Oct. 4th. Mr. Bacot, the house-surgeon, was called in the evening to see him, and found him sitting on the bed-chair (having just passed a motion), complaining of pain in his bowels. By the administration of stimulants at short intervals, he rallied from a state nearly approaching collapse.

October 5th. He was this morning quite free from pain, but his pulse was excessively small and weak.

At 2.30 p.m., when visited again, he was found in *articulo mortis*, and rapidly sank.

EXAMINATION OF THE BODY. *Chest.* The lungs were covered with recent false membrane, not uniting them to the costal pleura in front, although it did so behind. There was no tubercle. The lungs were crepitant, and buoyant in water. The pericardium contained a little fluid, and some fine adhesions united the roots of the vessels to the pericardium. The heart was of normal size. There was a large white patch on the anterior surface of the right ventricle, the walls of which were a quarter of an inch thick. The tricuspid valves were healthy; the pulmonary valve had fine reticulations on two of its segments. The wall of the left ventricle was half an inch thick. The aortic valve was thickened and opaque, and had some reticulations. The mitral valve also was thickened at the points of insertion of the chordæ tendinæ; and the opposite portion was puckered and greatly diminished in breadth.

Abdomen. This cavity being opened, a dark plum-coloured fluid escaped, and the intestines on the right of the median line were found to be encased in a coagulum of blood an inch thick. On close examination, the liver was found united to the right pillar of the diaphragm. The aorta and vena cava were imbedded in a mass of fibrin, extending from the aortic opening in the diaphragm to just above the iliac arteries. This mass was removed entire, and exposed an aneurismal sac, bounded by the right pillar of the diaphragm, the anterior inferior surface of the liver—the lobulus Spigelii projecting into the sac, and in front by a layer of thick lymph, together with the vena portæ and hepatic artery, which were moreover united by recent lymph to the lower edge of the liver. This cavity

was divided into two of unequal size, that attached to the aorta being as large as a walnut, and separated from the larger one by a thick layer of lymph, perforated with an opening of the size of a goose-quill, and having another opening, by which it communicated with the aorta, as large as a chicken's quill. This last opening was found just above the giving off of the arteries, which usually unite to form the celiac axis, but which in this case arose separately from the aorta. The aorta was roughened by a patch, apparently of atheroma, at this precise spot, without any dilatation, and was elsewhere smooth and healthy. The smaller cavity was rugose, like the lining membrane of the gall-bladder, and contained a tough, tawny coagulum. The larger one—twice the size of the smaller—appeared to be of more recent existence, and to be formed principally by adhesion of the parts and organs whereby it was naturally bounded.

REMARKS. In neither of these cases was the calibre of the aorta at all increased. In both, there was deposit in the inner coat, though very slight, and confined to the immediate neighbourhood of the perforation of the artery in the case of Whittle. In both, the cellular coat appeared to form the aneurismal sac, being dissected away by the infiltration of blood. Both patients were in the state of rheumatic cachexy, contracted under very similar circumstances. But in Whittle there was something more: the valvular heart-affection, and an abscess over the right shoulder-blade (not mentioned in the account of the autopsy).

It appears sufficiently clear that, in the case of Cockerell, the affection of the artery commenced with his rheumatic attack. The inflammation of the serous lining of the heart (endocarditis) was continued to that of the aorta, ending in atheroma of the vessel; the peculiar characteristics of which—fatty globules and crystalline matter—were distinctly visible under the microscope. Rokitsky affirms that this succeeds to hypertrophy of the lining membrane of the vessel in such cases.

In the case of Whittle, the incrustation in the aorta was so small and thin, that it may be doubted if it was of the same nature as that of Cockerell; and when it is remembered that there were two sacs—the inner one only containing a coagulum, and that, besides the coagulated blood, there was found in the abdomen a quantity of thick plum-juice-like fluid—we retain the impression then felt, that an abscess had given way. The outer and larger sac was probably that of an abscess, which had caused arteritis at the point of contact, with ulceration through its coats, and their dissection of its outer one by the effused blood, thus gradually causing the aneurismal sac. This conclusion is, however, somewhat at variance with the appearance which the larger sac presented, of being more recently formed than the smaller one.

The sudden pain in the belly, and the supervention of syncope in the recumbent posture, indicated internal hæmorrhage from the yielding of arterial coats, either by ulceration or aneurismal rupture. Happily, the cause of death was clearly demonstrated by the *post mortem* examination, and as clearly exhibited in the well prepared pathological specimens with which the remarks on the case were illustrated.

Dorchester, June 1855.

SUGAR OF MILK AS AN ARTICLE OF FOOD IN CONSUMPTION AND OTHER PULMONARY DISEASES.

By JAMES TURNBULL, M.D., Physician to the Liverpool Royal Infirmary, and Lecturer on Clinical Medicine to the Medical School.

Those who are familiar with Liebig's works are aware that he established, several years ago, the fact that all the most valuable substances used as food belong to one of two classes—the azotised, or plastic, which form the tissues of the

and replace the worn-out tissues; and the non-azotised, or combustive, which furnish food for the lungs, supporting respiration and animal heat. Now, it is a curious fact, which he also established, that, though the fibrin, albumen, and casein, which constitute the chief of the first or azotised class of alimentary substances, exist in vegetable as well as animal food, animals have not the power of forming in their own bodies any of those azotised alimentary principles. They are primarily derived from the vegetable kingdom; and the digestive organs of animals have no power of producing them, but merely of assimilating what has been already formed by plants, or previously drawn from the vegetable kingdom by some other animal. These views met with considerable opposition when they were first advanced; but their correctness is now generally admitted, and there is no essential difference in the chemical composition of fibrin procured from vegetables and that obtained from the flesh or the blood of an animal, or between vegetable and animal albumen or casein.

Of the other class of alimentary substances—the non-azotised—the chief use of which is to supply food for respiration and the support of animal heat, the principal are starch, sugar, oil or fat, and alcoholic liquors. These unite with the oxygen absorbed at the lungs, and are the chief source of the carbonic acid and watery vapour given off by these organs. They are, in fact, burnt by a process of slow combustion, which is the great source of the high temperature of animals.

It appeared to me that, as this function of the lungs must necessarily be more or less impeded in all pulmonary diseases, and as cod-liver oil had been found so beneficial in that particular disease, consumption, advantage would be gained by selecting from this, the non-azotised or combustive class of alimentary substances, such of them as would have the greatest tendency to unite readily with the oxygen absorbed at the lungs; and thus, in the disabled condition of these organs, to facilitate the performance of their functions.

I was thus led to inquire which of the non-azotised or combustive class of alimentary articles are most readily digested, and have the greatest affinity for oxygen. Sugar of milk is an article belonging to this class of aliments, which possesses these properties in a high degree, and is deserving of more attention than it has yet received as an article of food. I shall therefore state a few facts respecting it, which seem to me sufficiently interesting to be worthy of being brought under the notice of the profession.

There are three principal varieties of sugar—cane sugar, milk sugar, and grape sugar. They are closely allied in composition, though they differ considerably in chemical properties. All kinds of milk contain sugar of milk; but it is worthy of notice that asses' milk, which has always had a greater reputation than any other kind, as an article of food in consumption and other pulmonary diseases, contains the largest proportion, relative to the caseous and oleaginous principles, of any kind of milk. Whey, which consists almost entirely of sugar of milk, has also been found a useful article of diet in consumptive cases.

When we inquire into the chemical properties of milk sugar, we also find that it has so strong an attraction for oxygen, that, when dissolved with an alkali, it has the power of reducing more or less completely some of the metallic oxides. It is readily absorbed into the blood, which, being an alkaline fluid containing oxide of iron, furnishes the necessary conditions for its oxygenation. Besides this, its composition is such, that it must be readily converted into carbonic acid and water. There is only one other point in relation to its fitness to supply material for respiration, which I shall at present notice. It is the fact, originally pointed out by Liebig, and now admitted by physiologists, that one of the great offices of the liver is the preparation of combustive material for the respiratory process. This is a point which has not been sufficiently kept in view by medical men; but it is one of great practical interest, when we consider that the function of the lungs and that of the liver are so intimately connected and mutually

dependent, that derangement of the secreting function of the latter must necessarily interfere with the former, and may not improbably be one of the chief causes of a tubercular state of the blood. The liver prepares the combustive materials for respiration; and of this there are two sources, one being the worn-out tissues of the body, the hydro-carbonaceous part of which forms bile, and, being re-absorbed, is consumed at the lungs; the other is the saccharine and fatty matters of the food, which are consumed in a similar way. It would seem, however, that the liver has not only the power of preparing the latter, but also of forming saccharine at least, if not oleaginous matters, from the blood. A defect in this power may be one of the great causes of tubercular diseases; and if we can, by giving a ready formed oil which is stored up at certain times in the liver of the cod-fish, rectify to a great extent any defect in its action, so far at least as the oleaginous material for respiration is concerned, there is good reason to expect that still more may be gained by giving, in a ready formed state, the other combustive material, the saccharine.

The facts I have brought forward have led me to use sugar of milk in the treatment of consumption; and, as I have seen benefit from its use, I wish to recommend it as an article of food deserving of more attention in the treatment of this disease than it has yet received. I believe also that they embrace an important principle, applicable to the dietetic treatment of other diseases.

Liverpool, June 1st, 1853.

READY MODE OF APPLYING THE DOUCHE, AND OF ADMINISTERING INJECTIONS OF WATER.

By J. INGHAM IKIN, F.R.C.S.Eng.

IN directing the fitting up of a small Hospital for the Diseases of Women and Children, just opened in this town, I have adopted a simple and effectual plan for the application of the douche, and for the administration of water injections, both of which are very useful in the treatment of many disorders of women. As I am not aware that this exact mode of employing water has been recommended or used by the profession, I now call attention to it through the medium of our JOURNAL.

To every floor in the new hospital, hot and cold water is carried; the latter being supplied by the town water-works; the former, by a reservoir placed in the attic, heated by pipes connected with the kitchen fire. To the pipes and taps in the lavatory and bath-room, I have had additional screw taps attached at the side, to which is appended a length (about two yards) of gutta-percha tubing, of somewhat smaller diameter than that now commonly used for cleansing carriages, etc. There is, at the end of the elastic tube, a brass screw, to which terminal pipes of different kinds can be attached; for example, an ordinary straight one, with a single aperture; a vaginal one, with a number of orifices, as in a female syringe, etc. As the pressure on the water in the pipes (which communicate with the mains) is always considerable, it is expelled with great force, which can be regulated by the screw tap, at the will of the patient or nurse, according to circumstances and the effect produced. It is a simple and effectual mode of applying the douche, and of giving water injections.

The proper and judicious application of water, in the treatment of many diseases, either local or general, we should not overlook, nor allow quacks, hydropathists, and others, to obtain credit for modes of treatment which, in judicious hands, can be skilfully and discriminately used, though they will not be abused, or used merely as a means of *pumping* the pockets of the patient, and gulling the public.

As a shower bath, especially for children, I may add that I find the pneumatic apparatus (an old invention, I believe, recently come again into fashion) to be very convenient, especially when a severe shock is objectionable.

The cold sitz-bath is certainly a most convenient and useful form of bath, especially to females subject to leucorrhœa and relaxation of the muscular system.

The proper distinction now made between vaginal or epithelial leucorrhœa, and uterine, cervical, or mucous leucorrhœa, is eminently useful, and has been very accurately described by Dr. Tyler Smith. My own researches entirely confirm his views; and I feel indebted to him for his able investigations, which I hope to be able still further to support at a future time by the publication of some microscopic examinations and cases of my own.

This leads me to remark that, in the use of the glass speculum, without the covering—that is, a transparent one—some risk is run of its breaking, but only when it is improperly made, or too violently introduced. I would, however, caution against using it without the plug, as the edges may lacerate the vagina. A plug of firm sponge answers very well, and can be readily withdrawn. The bivalve metallic speculum, I agree with Dr. Bennet, is, on the whole, by far the most useful instrument.

In concluding this desultory notice, I may repeat what has been so often proved by higher authorities, that, with regard to the use and application of water in the treatment of disease—that the claims of the hydropathists, or those of the founder of that sect, are very inferior to those of Currie and many other regular scientific practitioners. I may be allowed to add that, nearly twenty years since, I wrote a series of papers on the German Mineral Springs, for the *Lancet*, in which the use of cold water, the douche and the bath in all their forms, were pointed out as eminently useful in many diseases, both in man and the lower animals. The practice of intelligent physicians at the different spas, both at home and abroad, had proved this fact long before hydropathy was known.

Two great lessons the profession have, or should have, derived, from the temporary success amongst certain classes of hydropathy and homœopathy: these are, first, never carelessly to overlook the remedial efficiency of water, and its various forms of application; and second, to attend more to the diet and habits, and general hygiene of patients, and to discard the system of *overdosing* (I only say *overdosing*), and ringing the changes on purgatives, diuretics, alteratives, tonics, etc., etc., when such agents are not *absolutely* required; or pressing attendance beyond reasonable limits. The charge for attendance and advice will, in the majority of cases, be much more willingly paid, than a bill of the old school for mixtures, pills, and potions.

Leeds, June 13th, 1858.

BIBLIOGRAPHICAL NOTICES.

PRACTICAL TREATISE ON DISEASES OF THE SKIN. By J. MOORE NELIGAN, M.D., M.R.I.A., Hon. Fellow of the Society of Physicians of Sweden, Physician to Jervis Street Hospital, and Lecturer on Medicine at the Dublin Hospital School. pp. 429. Dublin: 1852.

THIS book opens with a chapter on the classification of skin-diseases, and several interesting general observations are made. The following remarks, on the effect of skin-diseases on the system generally, will interest some of our readers:

"An important view in which diseases of the skin must be regarded, and one that adds much to their interest, is the effect they produce upon the system generally. We sometimes find that, in persons who have laboured even for a long time under these affections, but little constitutional derangement is, in many cases, caused by them; so little indeed, that it has been doubted whether the existence of an affection of the skin, in a chronic form, tends to shorten life, or should be taken into account in coming to a conclusion as to eligibility, in a medical examination, for assurance. For my own part, I believe that, as long as the individual remains unaffected with any acute or inflammatory affection, the existence of a skin-disease will not in any respect diminish the average chances of longevity."

These views, coming as they do from so practical an observer as Dr. NELIGAN, are highly valuable.

After sketching the various classifications of skin-diseases that have been made by writers, and after showing how difficult a thing it is to make an artificial classification that shall be at once truthful and simple, Dr. Neligan proposes "to divide cutaneous diseases into ten groups or orders, as follow:—1. Exanthemata; 2. Vesiculæ; 3. Pustulæ; 4. Papulæ; 5. Squamæ; 6. Hypertrophies; 7. Hæmorrhagiæ; 8. Maculæ; 9. Cancrodes; 10. Dermaphytæ; adding two supplementary groups, Syphilides, and Diseases of the Appendages of the Skin."

We congratulate the profession on being possessed of so simple an arrangement of what are called cutaneous diseases; but we should congratulate it much more, if we could have seen the author before us dispensing with classification altogether.

How long, we wonder, how long, will the system of making disorders, and of transforming the symptoms of disease into diseases themselves, continue? Dr. Neligan says, that the past plans of arranging skin-diseases into classes have been either too artificial or too complicated. This is true. Dr. Neligan might have gone further, and said what we have every reason to believe he thinks, that it is monstrously absurd to speak of any appearance on the skin, except as of a sign indicating a derangement of one or other of the leading functions of the body. Let us give an illustration of what we mean. If the skin be covered with a white scurf, or be cracked and fissured here and there, it is looked at with a most piercing glance, and is said to be suffering from some extraordinary disease with a still more extraordinary name: but let the tongue, which is but a continuation of the surface of the skin, be the seat of these appearances, and straightway they lose their importance altogether; the tongue is said to be foul, or dry, or fissured, and to indicate the condition of the system; but the tongue is not said to be suffering from any special disease: and the man who might say that it was, would be rightly considered as something little short of what the Scotch call "an innocent". Look at the matter reversed. Let the skin be universally pale, and sweating at every pore, and it is never described as suffering from any disorder, but is said to be in a state that expresses in some way the nature of another disease, say consumption. Let it be unusually dry, shrivelled, and dingy, and again it shall not be diseased, but in a condition indicating some such disorder as diabetes. Or again, let it be yellow and dry, and it shall only point out that the liver is undergoing abnormal change. But let the skin be red and dry, or red and rough, or spotted in half a dozen places, and at once it is petted like a drawing-room fop, is considered as in a very bad state, is treated peculiarly, and is described as suffering from a vesicular, an exanthematous, or a pustular disease. Surely such classification of diseases is not merely artificial, but is also *exceedingly* superficial.

However, we ought not to find fault with Dr. Neligan. Reforms must proceed slowly to proceed surely; and, until the professional mind is fully prepared to receive the doctrine, that disease is an unity with a variety of phenomena, it is better not to put the doctrine fully into practice, but to lead the mind toward it by simplifying old classifications, as Dr. Neligan has now done.

We have not much space for following our author through his thirteen chapters on the symptoms and treatment of the diseases included in those classes which he has proposed, and we have copied. He does not admit measles or scarlet fever into his list of exanthematous diseases; but he treats largely on erysipelas. Here is a passage which refers to the local treatment of erysipelas:

"When erysipelas is spreading rapidly, although superficially, over the cutaneous surface, the inflammation still persisting in the parts where it first appeared, inunction with mercurial ointment has in my experience more effect than any other local application in checking its progress. The mercurial ointment, to every ounce of which a drachm of glycerine has been added, should be smeared thickly

inflamed surface, and on the sound skin for a considerable distance beyond ; it need be applied only once in the twenty-four hours, and, if any symptoms of salivation be produced, its employment should be at once stopped."

It would be interesting to know whether salivations ever would be produced by rubbing mercurial ointment over an erysipelatous surface ; and if Dr Neligan has at any time seen such an effect, he is blameable for not stating the fact. We notice that he believes strongly in the contagious nature of erysipelas.

Our readers who are accustomed to meet with affections of the skin, and are expected to cure them, will sympathise with us when we say that we turned with considerable eagerness to that part of our author's work which refers to the treatment of "chronic eczema". With the exception, however, of finding that the lead cerate was rendered a more useful local application by having eight or ten minims of chloroform, and two drachms of glycerine, added to every ounce, we cannot confess to have been at all enlightened on the treatment of that troublesome disease.

Passing over many pages, we rest for a minute on those which contain Dr. Neligan's views as to the treatment of psoriasis. These views have nothing that can be considered original. We had hoped that they might have said something for or against the practice introduced by Dr. Golding Bird, and so ably explained by Dr. Easton, of Glasgow, of treating psoriasis with full doses of acetate of potash ; a practice which has once succeeded admirably in a case under our own care. Dr. Neligan is, however, silent on this matter. The fresh water tepid bath is, with him, the best local application. At page 233, the following passage occurs :—

"In strong, healthy, plethoric young persons of either sex, when the eruption is of the guttated form, or affects only a small portion of the skin, its progress will generally be stopped, and a cure effected by the use of tolerably active saline cathartics every second and third day, preceded by a general blood-letting, and the daily use of a *fresh* water bath, at the temperature of 90°."

In old persons, he employs stimulating diaphoretics ; in scrofulous children, cod-liver oil ; and in aggravated cases, arsenic combined with a preparation of iodine.

The leading novelty in Dr. Neligan's book is his mode of treatment in cases of purpura. On this subject, he thus observes :—

"Some years ago I published an essay on the treatment of purpura by large doses of turpentine, and illustrated the efficacy of this remedy when thus administered, by a report of several cases in which it proved successful. Since then I have continued to employ it both in the simple and hæmorrhagic forms of the disease ; and my additional experience is fully confirmatory of the views then propounded. It must be given in doses sufficiently large to act as a purgative, from one to two ounces, according to the age and strength of the patient for adults, and in a proportionate dose for children."

Further on, he says :—

"The beneficial action of the turpentine in this disease is two-fold. First, it is a diffusible stimulant and styptic, which, when conveyed into the circulation through the digestive organs, is exhaled from the system by means chiefly of the mucous surfaces, as is manifested by the odour of the breath, and of the various secretions and excretions. It is thus consequently brought directly into contact with the capillary circulation, from which, in this disease, the hæmorrhage takes place. And second, the free employment of purgatives in the treatment of purpura having been long since proved to be attended with most successful results, the administration of oil of turpentine to fulfil this indication is especially serviceable, in consequence of its not being a debilitant." (pp. 306, 307.)

On this practice and theory, we have no remarks to offer. Our own treatment of purpura always consists in the employment of the citrate of quinine and iron, with occasional gentle purges, and we have found this treatment most successful in several cases.

Dr. Neligan's last chapter is on the therapeutics of diseases of the skin, and has reference to the value of warm baths, gelatine baths, alkaline baths, iodine baths, sulphur

baths, mercurial baths, cataplasms, caustics, lotions, cerates, powders, soaps, and bandages, and to several medicines for internal administration. The chapter is interesting and useful, but is greatly disfigured, as indeed is much of the book, with the introduction of numerous dogmatical formulæ. If an author has seen a remedy do service in any disorder, let him say so by all means ; he is culpable if he does not ; but let him state the simple fact, and not tattoo his pages with endless recipes and execrable Latin. No professional man, we hope, is in so low a state of ignorance, and so devoid of the knowledge of the method of prescribing, as to be obliged to copy formulæ from books. An indolent student may, perchance, transcribe a formula, and reproduce it ; but to the student the proceeding would be highly injurious, inasmuch as it would encourage him in indolence, and take from him that degree of self-reliance and familiarity with the implements of his art, which every medical practitioner ought to feel and cultivate. We are not, in these remarks, criticising Dr. Neligan especially, but a vicious practice which ought to be abated, and which we regret to see is patronized by an author deservedly esteemed in pharmacy and therapeutics.

Though we have ventured to speak freely upon some points in which we differ from Dr. Neligan, we must say that his work, as a whole, is one which inculcates practical precepts.

DES SOURDS-MUETS. INTRODUCTION A L'ÉTUDE MÉDICALE ET PHILOSOPHIQUE DE LA SURDI-MUTITÉ. PAR M. E. HUBERT-VALLEROUX, Docteur en Médecine de la Faculté de Paris. Svo. pp. 121. Paris : 1853.

[THE DEAF AND DUMB. AN INTRODUCTION TO THE MEDICAL AND PHILOSOPHICAL STUDY OF DEAF-DUMBNESS. By Dr. E. HUBERT-VALLEROUX. Paris : 1853.]

THE object of this work, as stated by Dr. HUBERT-VALLEROUX, is to classify the diseases from which deaf-dumbness is derived, to examine its causes, to point out its characters and nature, and to trace them in their different phases, in order to deduce therefrom rules for rational treatment.

The work is divided into eight chapters.

Chapter I contains Introductory Observations, referring to the object of the work, to the number, intellect, moral condition, and character of the deaf and dumb, to the disastrous results of deaf-dumbness, and to the importance of treatment.

The number of deaf and dumb persons in Europe is calculated by Dr. Hubert-Valleroux to be three hundred thousand.

The author, in commenting on their intellectual condition, observes that when, after years of labour, the deaf and dumb have gained some power of acquiring and communicating ideas, they are ten or fifteen years behind other persons. They have been remarked to readily become acquainted with the visible characters of objects ; but the great majority are precluded from passing from the region of physics to that of metaphysics. When perfectly uneducated, their condition is often analogous to that of some savage tribes.

The deprivation of hearing and speech

"Reacts also on the moral and effective feelings, creates certain habits, and influences the character. Under this double infirmity, the general constitution and the temperament of its subjects undergo even remarkable modifications. . . . Two paths, which have been described by poets of all ages, and of all nations, are presented to man on his entrance into social life. The one is the wide and easy road, into which enter those who obey their instincts, who follow the law called *natural*, or of the flesh, common to man and animals. The other is the narrow road, the rugged path into which penetrate those only who possess faith, and who, sustained by the hope of another life, voluntarily tread under foot the enjoyments of the former. If man remains free to the impulses of nature, if he knows not the road which he should take, he blindly follows the law of instinct, like the brute ; abandoned to himself, he obeys the laws of gravitation. And when men are found in society who

practise devotion even to suffering and death, they are those who possess religious or social faith—the faith which animates martyrs. This faith always involves the supposition of instruction of the highest order, since it rests on purely spiritual objects. It coincides, moreover, with the existence of a civilised society and a complete language; for the ideas of devotion and of charity, as well as the words which express them, are unknown in rudimentary states of society. . . .

"Benevolence, mildness, equanimity, are not mere virtues arising from temperament, as some assert them to be; they are real virtues, the fruits of the moral sentiment combined with the will. How otherwise can we explain those unexpected and sudden transformations from intemperance to sobriety, from anger to mildness of temper, etc., in men who have undergone no organic change, who have felt no pain, but who have only acted under the influence of a new conviction or belief? Why should not the same results be produced in the deaf and dumb, if they could receive an instruction as extensive and as complete as that of those who can speak?

"Before receiving the special education which is indispensable to enable him to know and to practise social duties, the deaf and dumb person is choleric, revengeful, idle, jealous, and gluttonous: he is, in a word, what each of us would be if we followed our instincts, and lived under the much vaunted empire of natural laws. In the absence of virtues, the decencies of society protect us from these failings and vices, while the perception of these decencies is one of the last fruits which the deaf and dumb person derives from his education. As the education advances, the disorder diminishes, but it is with great difficulty that it totally disappears." (pp. 7-10.)

The author gives some quotations from the works of the Abbé Sicard and of M. Itard, which coincide with those which we have transcribed.

Chapter II contains Historical Considerations on Otology, in which the author points out that our knowledge of this subject is very recent. Itard was the first who, in 1821, published a connected series of observations on deaf-dumbness.

Chapter III treats of the Causes of Deaf-Dumbness. In it Dr. Hubert-Valleroux gives some interesting statistics. He says:

"Considered in its totality, the deaf and dumb population is very unequally distributed over different parts of the globe. It alternates in a general manner with that of the blind, so that one increases while the other diminishes, and *vice versa*. As we approach the equator, we find blindness predominating, as in India, Egypt, and Ethiopia. It predominates, also, towards the poles, among the Laplanders, the Samoiedes, and the Esquimaux. Deafness, however, is most prevalent in temperate countries, and especially in mountainous regions, as Switzerland. In that country we find a canton—Berne, for example—which has not less than one deaf and dumb person in 205 inhabitants; the district of Schwarzenburg, which has one in 103; and the *commune* of Weyach, which contains one in 44!

"In the space of a few miles, in the basin of the Aar, Switzerland presents a remarkable example of the contrast which I have just pointed out. The low and damp western part, as well as the eastern part, which is connected with the Alps, both contain a large number of deaf and dumb, and few blind persons. The southern part, a lower part of Mount Jura, contains, on the other hand, very few deaf and dumb, while the blind abound." (pp. 10-20.)

The causes of this antagonism are mainly to be sought for in the influence or deprivation of light. In Egypt, and in the Polar regions, the blind are found; in the former country, the direct and reflected rays of the sun are the cause; in the latter, the constant presence of snow, and the frequency of the aurora borealis. Deaf-dumbness, on the other hand, is found in the regions where there is a deprivation of light. Connected with this condition is commonly found that of constant coldness and humidity; and to this the author attaches much importance.

As causes of deaf-dumbness, are also to be reckoned the vices of social and economic institutions, the peculiar condition of certain families, and especially the defective education of children, as among the poor.

Hereditary tendency, not only in a direct line, but also collateral; intermarriage of relatives, to which the author would attribute the frequency of deaf-dumbness in the

aristocratic families of Spain; passions, emotions, fright occurring to women during pregnancy, are all referred to as causes of congenital deaf-dumbness.

Those families in whom deaf and dumb children are found present singular anomalies. In one, all the children of one sex will be deaf and dumb, while the others can speak. In another, there will be an alternation of the deaf and dumb with the perfect child; the series being sometimes of one, sometimes of two or three.

As causes of deafness leading to dumbness in children, may be mentioned the exanthemata, small-pox, measles, scarlet fever, etc. In the Leipzig Institution, out of twenty-five cases, fourteen arose from scarlet fever, six from measles, and only five from other diseases. In Italy, Germany, England, the United States, and France, however, the number arising from exanthemata, although considerable, is not so great.

In concluding this chapter, the author observes that he "would have to notice almost all the severe diseases of infancy, if he desired to enumerate all the causes of deaf-dumbness which are presented in practice."

In chapter IV, Dr. Hubert-Valleroux treats of the Characters of Deaf-Dumbness. He describes the conduct of the deaf and dumb, contrasting that of the educated with that of the uneducated state. He also refers to the lymphatic temperament, and to a tendency to catarrhal affections of the mucous membranes, as being very frequent. The deaf and dumb, also, present a low degree of "organic sympathy", so that disease may proceed to a great extent before there is any manifestation of pain.

According to Dr. Hubert-Valleroux, deaf-dumbness is more frequently acquired than is generally supposed. Itard at first believed it to be mostly congenital; but he subsequently modified this opinion. The author says:

"To become convinced of the frequency of acquired deaf-dumbness, we can make the children in any institution pronounce the few words which they almost all know. We soon recognise from the accent, which cannot be mistaken by a practised ear, that a large number of those who are entered as deaf and dumb from birth, have spoken at some time. In some schools, as those of Bordeaux and Nancy, where the previous history of each child is carefully collected, we read that most have heard up to the age of eight or ten months, a year, or more; and the information furnished by the families will allow the infirmity to be referred to convulsions, scarlet fever, etc. Hence we infallibly arrive at the conclusion, that congenital deafness is as rare as acquired deaf-dumbness is common." (pp. 41-2.)

The author discusses and refutes the proposition advanced by Itard, that deaf-dumbness depends on paralysis of the acoustic nerves. He shows an analogy, with regard to the circumstances under which they are produced, between deaf-dumbness and ophthalmia neonatorum; and concludes the chapter in the following words:—

"Itard was right when, forgetting what he had said about paralysis of the auditory nerve, he added these words: 'The causes of deaf-dumbness may be all those which weaken or destroy hearing in the adult.' In fact, injuries, morbid adhesions, the presence of foreign bodies in the ears, caries, necrosis, catarrhal, nervous, or rheumatic affections, etc.,—all these lesions which, in the adult, produce simple deafness, are recognised as organic causes of deaf-dumbness. This statement is confirmed by the fact, that the remedies which are found beneficial in adults, are also those which, in the analogous affections, have been successfully used in the treatment of the deaf and dumb." (p. 52.)

Chapter V treats of the Prognosis of Deaf-Dumbness. The curability of the affection in all cases has been most absurdly insisted on by some persons; and Mesmerism, animal magnetism, and electricity, have been vaunted as infallible remedies. On the other hand, some physicians have affirmed the absolute incurability of all deaf and dumb persons: "an assertion", ironically says Dr. Hubert-Valleroux, "full of modesty on the part of these learned gentlemen, who thus declare that they possess not only a complete knowledge of the past and the present of otology, but also an insight into its future progress."

The author shows that the medium between these opinions

is the correct one. Deaf-dumbness is susceptible of cure, in some cases spontaneously; in others, in consequence of some accidental disease; and in others, by judicious treatment: and he supports this view by the recital of cases. The following are the circumstances to be attended to in forming a prognosis.

"The deaf and dumb individual who offers the best chance of recovery under treatment is he whose deafness is *accidental*, and has supervened at an age when children have already begun to hear and to speak, and who still preserves some remains of hearing and speech. If the organic lesion, the first cause of the infirmity, has its seat external to the nervous centres; if the child is intelligent, and has no brothers or sisters in the same state as himself; if he is the offspring of healthy parents, not related by blood; and if he has yet undergone no treatment, the chances of recovery will be numerous; and they will almost amount to certainty, if all the above conditions are found combined. On the other hand, they will lose their value in proportion as one or more of these conditions are wanting; and recovery can scarcely be hoped for when they are all absent. It is possible to ameliorate certain cases of congenital deafness, and those which supervene in the early months of life on eruptive or catarrhal fevers: I have seen more than one instance. But I have not yet seen recovery, or even relief, in persons attacked with deafness after fevers or cerebral lesions.

"Far be it from me, however, to pretend to assert a definite prognosis, especially an unfavourable one, in deaf-dumbness. I have too often experienced how great and how unknown are the resources of the *vis medicatrix nature*; and I too well know the extent of our ignorance of otology, to throw off, with regard to this subject, the most prudent reserve." (pp. 83-4.)

In chapter vi, the Treatment of Deaf-Dumbness is described.

In 1786, M. Felix Merle treated the affection by the introduction into the ear, night and morning during a month, of a stimulant application, composed of an infusion of asarabacca and other herbs. In this way he treated twenty-seven individuals in Bordeaux, without regard to the nature of their affection, to their temperament, or to their idiosyncrasies. The result produced was a painful inflammation, which aggravated the disease in most of the patients, but produced improvement in one, and cured another.

About the commencement of the present century, M. Varroine believed that the cause of the affection under consideration was paralysis of the nerves of hearing and of the tongue; and in a patient under his treatment, he referred the dumbness to enlargement of the latter organ. He therefore applied moxas, one at the nape of the neck, and the other under the chin. These produced much swelling, inflammation, and suppuration. This patient recovered; but Dr. Hubert-Valleroux remarks, "that this treatment was as likely to kill the patient as to cure the disease". This method obtained so much notoriety, that, according to Itard, many of the deaf and dumb admitted at that time into the institution at Paris bore numerous cicatrices of moxas.

Itard himself tried the remedies recommended by Merle and Varroine, with little or no advantage. And not only was this empirical treatment useless, but it also gave rise to accidents of more than one kind, often very severe.

Dr. Hubert-Valleroux next proceeds to describe the treatment which he employs; but he first makes some very just observations, which we transcribe.

"It is with heroic remedies as with surgical operations: recourse should not be had to them until milder means have failed, or must necessarily fail. We are not justified in inflicting severe pain on patients, except to remove greater pain or inevitable danger. Except under these conditions, the administration of heroic remedies, and the performance of surgical mutilations, ought to be severely interdicted. For these reasons, I dare to blame the conduct of Varroine, of Merle, and even of Itard, our honoured master. Although deaf-dumbness is, without dispute, the most severe of human afflictions, it nevertheless leaves perfect the principles of life; and no one has a right to rashly interfere with that sacred deposit. Our knowledge of diseases of the ear is at present too limited to authorise the employment of heroic means. It is no doubt painful to remain disarmed in the presence of so great misery; but here patience

is by no means culpable, while unseasonable activity may become so. The rigorous observation of these precepts has perhaps prevented me from obtaining all the success which has seemed possible; but it has safely preserved me from dangers which I knew to be inevitable under an opposite line of conduct." (pp. 90-1.)

The following is the author's description of the treatment which he employs:—

"Partial excision of enlarged tonsils is the most painful operation which I have performed in the treatment of deafness; and to this I have rarely had recourse. I have extensively practised catheterism of the Eustachian tubes, and injections of medicated vapours into the cavity of the tympanum. The substances which I have most frequently used for this purpose have been the resins and gum-resins, and the essential oils of thyme, lavender, rosemary, balm, etc.; and experience has taught me to vary these according to circumstances, in order to render the treatment efficacious. I have also used, but very rarely, the vapour of ether, either pure, or more frequently combined with ammonia. I have sometimes touched the throat with a stick of nitrate of silver, or with a brush dipped in a solution of that salt; and I daily employ for that purpose a saturated solution of tannin. The most energetic cutaneous revulsive which I have as yet found it necessary to use, is a mixture of three parts of almond oil with one of croton oil; this I apply to the skin near the angle of the lower jaw, in order to produce a redness which continues during from two to five days. I have been able to confirm the advantages of a practice recommended by Itard, consisting in acting on the scalp by frictions and lotions. This method often succeeds when deafness is produced by the disappearance of parotitis, or by the sudden repression of an exanthem. I commence by having the hair cut, and I order, in the evening, friction for ten minutes over the whole of the head; the applications used being soft soap, alkaline solutions of different degrees of strength, or a rubefacient liniment, according to the effect desired to be produced. The head is then wiped, and covered with a flannel cap, over which is placed a covering of waxed taffetas. Moisture is soon produced, and is succeeded by perspiration, which continues during the night. In the morning, the head is wiped with flannel, and is kept well covered during the day. I prescribe also lotions of water, lukewarm at first, then quite cold, to the shoulders, the chest, and even over the whole body in persons who easily take cold. I know of no more efficacious means of preventing the catarrhal and rheumatic affections which so often compromise the most happy cures of deafness.

"As internal remedies, in certain cases of congestion of the pharynx and larynx, I prescribe emetics, laxatives, purgatives, alteratives, tonics, etc. These medicines, however, have no other object than that of fulfilling general indications of treatment." (pp. 91-3.)

Dr. Hubert-Valleroux believes that great benefit would be derived from an institution analogous to the cretin asylum of Dr. Guggenbühl. He says:—

"If, among the true friends of humanity (more numerous, thank God, than is generally supposed), there are a physician, and an instructor, still young, rich, and sufficiently devoted to dedicate their lives and fortune to a simply useful work, which will bring them neither distinctions nor social dignities, this is the advice which I would give them. In one of those beautiful situations so common on the Alps and Pyrenees, they should build, half way up the mountain, equally removed from the region of snow and from the heavy atmosphere of the valley, an institution intended for the medical and pedagogic treatment of the deaf and dumb: it should be exposed to the east and south, and protected from the frosts and the north wind by the mountain, and by well distributed plantations. The soil should be perfectly permeable and dry; and well arranged declivities should afford an easy and complete escape to the rain-water.

"In the interior of the building, all should be simple and in good taste: no sacrifice should be made to luxury, but, on the other hand, nothing should be refused to hygiene. The apartments should be large, dry, and well ventilated; the means of communication easy: there should be order and economy every where, and profusion and neglect nowhere. Pure water should be distributed in abundance through all parts of the establishment, for the different usages of life, and for the maintenance of cleanliness. The dormitories should be rather numerous than large; the beds should be well distributed; and a soft bed should be proscribed as pernicious.

"The food should be simple, but of the best quality."

tonic rather than light. The quantity of wine should be greater than is usually allowed to children; for the deaf and dumb are of a lymphatic temperament, and require strengthening measures. On the outside of the institution, there should be, in a large lawn, apparatus for sports, especially for gymnastics; and a covered gallery should be provided for the same objects in rainy weather.

"The inmates should be chosen from among the deaf and dumb who afford the best chances of cure. The neighbouring valleys would furnish more than enough.

"The mere fact of removal from the damp and unhealthy habitations where they have contracted their disease, to a healthy establishment, would produce a happy change in the condition of the patients; and no less advantage would be gained in clothing, food, and exercise. Cleanliness, plenty, and careful attendance, in place of misery, privation, and neglect, would thus form the first step in diminishing the distance which separates them from those who have the power of speech.

"Medicine and instruction would naturally be called on to complete the work. The duty of the physician would be easy, because he would only have to treat selected subjects, whose previous history was known to him; and he would not have to fear that his prescriptions would be neglected, because he would himself superintend their administration. The instructor would be powerfully aided by those half-deaf individuals, to render whom entirely dumb so much trouble is taken in our special schools. Still more than those who speak, the little deaf and dumb are proud of their knowledge, and happy to exhibit it. They would thus be eager to stimulate their less advanced companions, to teach them what they knew, and to acquire for themselves new ideas. In this mutual and constant system of instruction, in this emulation, kept within limits where it does not become a fault, would be found united the best conditions of education. Certainly, if analogy and induction have the same value in medicine and instruction as in other sciences, we may securely predict that the success obtained in such an establishment would not be inferior to that which Dr. Guggenbühl has realized in the treatment of cretinism." (pp. 96-9.)

Chapter VII treats of the Instruction of the Deaf and Dumb; and its main object is to show that time and practice are required for the perfect restoration of speech. Sounds may be heard; but their combination is not at once perceived; nor, when perceived, can it at once be reproduced by the organs of speech.

Chapter VIII contains Philosophical Considerations on Language. In this chapter, the author discusses the question, whether speech is innate or acquired; and produces several arguments against the former opinion. He shows that the difficulty is much greater in teaching an adult to speak than a child.

This interesting work, we learn from some incidental observations, is preliminary to a larger one on the same subject, which Dr. Hubert-Valleroux is about to publish. Judging from what he has already done, we can truly say, that we believe him to be admirably qualified for the task.

VACCINATION CONSIDERED IN RELATION TO THE PUBLIC HEALTH: WITH INQUIRIES AND SUGGESTIONS THEREON. A Letter addressed to the Right Honourable the Lord Viscount Morpeth. By JOHN MARSHALL. Pamphlet. pp. 34. London: 1847.

MR. MARSHALL addressed this letter to Lord Morpeth (now Earl of Carlisle) six years ago; but its practical bearing on the now agitated subject of the extension of vaccination convinces us that an outline of the views which it contains will be interesting to our readers.

The author first shews that, though the Vaccination Extension Act of 1840 has been productive of much advantage, it has still failed in diminishing small-pox to a desirable or possible extent. In the course of his observations under this head, he gives the following explanation of the fluctuations observed in the mortality from small-pox in different years.

"The returns for the several years, from 1840 to 1846 inclusive, are, 1235, 1053; 360, 438; 1804, 909; and 257; so that they exhibit alternate periods of high and low mortality, consisting of two years each. Now, the victims of any particular

epidemic visitation of small-pox are, as is well known, principally, nay, almost entirely, drawn from that portion of the population in which vaccination has never been performed. Each fatal case of this kind must be understood (according to the computed rate of mortality amongst the *unvaccinated*, viz., one in four) to represent at least three other cases of small-pox, occurring also in the unvaccinated class, but terminating favourably. For every 1000 deaths (of unvaccinated persons) in such an epidemic, about 4000 in all must, therefore, have suffered from the disease; and as the survivors are henceforth as effectually protected from the further invasion of small-pox as if they had been originally vaccinated, it is clear that the 1000 supposed deaths are an index of an actual diminution of the hitherto unprotected part of the population, to the amount of 4000 persons."

He then shows that "vaccination is not now universally employed": that it "is not regularly and evenly applied": and that it "has not, under existing arrangements, a promise of being a permanent habit among the whole people".

Mr. Marshall next proceeds to point out measures for remedying these defects. He is opposed to a compulsory system. "Among the military, and some other classes, this has been allowed; but, as a general measure, it is opposed to our strong though often prejudiced love of individual freedom. State medicine might advise, but state policy would not sanction, the universal adoption of compulsion in these matters."

The following are the measures which he proposes for the extension of vaccination:—

"I. To make it a condition (by an Order of the Committee of the Privy Council on Education or otherwise), on the part of *all schools which do or shall hereafter receive a grant from the Government education funds*, that a regulation be immediately adopted and enforced by them, to the following effect—viz., that no child shall be received into or continue at such school, unless it shall previously have been vaccinated or have had small-pox; or unless it be submitted to vaccination within one month from the date of its admission into the school.

"II. To require and empower the officers of health to be appointed under the Towns Improvement Clauses Act, or the Health of Towns Act (by the introduction of words or of a special clause to that effect), to visit and inspect, on due notice given, *all schools and seminaries whatsoever*, for the purpose of examining the children, and of ascertaining and reporting on their condition, in reference to vaccination and previous illness from small-pox."

The results to be anticipated from the carrying out these measures are thus stated.

"It has been estimated that one-fourth of the population of this country are between the ages of 3 and 15,—extremes which may be said to embrace the school-educational career. There are upwards of four millions of such children in England and Wales; but of these, owing to illness, occupation, want of means, or other causes, all are not at school at one time.

"Too many never reach a school at all; but it is *sincerely* to be hoped, when such strenuous efforts are being made in the cause of education, and when schools are open even for the poor, the friendless, and the ragged, that the time is approaching rapidly when all who are not educated privately, will at some time or another be found at school.

"Schools may be regarded, indeed, as social *toll-gates*, through which, along the highway of life, almost the whole of the youthful population must defile. Here, it is proposed that the passport of vaccination shall be demanded of them; and since this condition would be required at the *outset* of their educational course,—which, among the poor especially, begins at a very early age, with attendance at an Infant school,—it follows that the means so taken to ensure the fact of vaccination would operate, not only on the school-population, but on the *infant* population of the kingdom. So much the greater benefit would accrue to themselves and to the community.

"At its commencement, the inspection would, of course, embrace a class of children much older than it would subsequently supervise.

"The unavoidable necessity for vaccination, as a condition of a child's being hereafter admitted into a school, would have a retrospective effect in removing the prejudices and quickening the assent of the parent to the early performance of that operation.

"By those direct inspections which I have ventured to advo-

cate, the relatively protected or unprotected state of the school-population in each locality would at once be revealed, with all its individual details. The very persons who were still unprotected by vaccination or by small-pox would be singled out and rendered accessible: none could escape:—the finger of preservation could be laid upon them:—the evil would be exposed at its root; and society would thus be enabled to attain and perpetuate a state of security, which, under existing arrangements, it is utterly impossible to reach.

"But, independent of this direct good, the collateral benefits of inspection would be great. The periodical visits of the officers of health being heard of everywhere, and spoken of by everybody, would maintain a continual and wholesome interest on the subject of vaccination, which, at present, is only excited by the temporary alarm created by wayward visitations of small-pox. The stimulus of contact with the officer of health would be more direct, more special, and perhaps also less likely to produce casual opposition in the public mind, than any which can be applied by the poor-law authorities. The two sets of functionaries, however, would cooperate, not interfere, with each other; the one, by arousing the activity of the public vaccinators, the other, by influencing the public themselves.

"It is, perhaps, unnecessary to advert to another advantage incidental to these visits of an officer of health. Under circumstances of danger, and in seasons of affliction from epidemic or contagious disease, domiciliary visits on his part are much needed for the preservation of individual and public health; and, in this particular instance of vaccination, the motive and reasonableness of his inquiry would be so evident, as at once to establish a favourable impression concerning the utility and benevolence of the duties to be performed by him."

Mr. Marshall made a laborious inquiry into the state of poor children in forty-three schools—twenty-three in the country and twenty in the metropolis—containing in all 4191 children.

"Of the total number of children examined, viz. 4191, 3408 had been vaccinated; but 783 had never experienced the benefit of that practice, or about eighteen and a-half per cent. Of the 3408 vaccinated, 148 had had small-pox since, and 3260 had escaped, the proportion of sufferers being only four and one-third per cent.; whereas of the 783 unvaccinated, no less than 400 had had small-pox, or fifty-one per cent. Lastly, the residue of unprotected is 383 children, or nine and one-tenth per cent."

He next points out the relative extent of vaccination in the metropolitan, country, and Jews' schools. The latter are given separately, as they present some remarkable features, very creditable to that people.

"The proportion of unvaccinated amongst all the children both of town and country (the Jews being specially excluded) is twenty-one per cent. !

"The ratio of unvaccinated in the metropolis is fourteen per cent., and in the country schools, twenty-four per cent.; so that vaccination is more carefully attended to in the former.

"Among the Jewish children, vaccination is performed with a completeness far surpassing the country or metropolitan schools taken generally, the proportion unvaccinated among them being only five and a-half per cent. The peculiar care which, it seems, even the humblest of that ancient people bestow upon the practice of vaccination, is a highly interesting fact. The well-known tendency of the Mosaic legislation to the preservation of individual and public health, has, in this instance, wisely been allowed to prevail over the presumed disposition of the Jews to restrict themselves to the letter of its injunctions.

"The fact is in itself an illustration of the possibility of a more complete observance of vaccination by all classes of the people; and it was satisfactory to find, as if in support of the proposed enforcement of a condition as to vaccination in the case of certain schools, that such a regulation is actually contained in the printed rules of the Jews' Infant school.

"It appears that, whilst in the metropolis there is a comparative decrease in the proportion of unvaccinated since the passing of the Vaccination Act, this is not so in the country schools. In this respect, too, it will also be observed, that a greater improvement has been effected amongst the Jews than in the Christian schools. The unvaccinated children amongst their very poorest (!) population, born since 1840, being only one and three-quarters per cent. ! Why should not all the kingdom be equally well protected?"

The per centage of small-pox cases is stated to be as follows:—

1. In country schools; among the vaccinated, 6·2; among the unvaccinated, 44.

2. In metropolitan schools; among the vaccinated, 3·2; among the unvaccinated, 60.

3. In Jews' schools; among the vaccinated, 1·1; among the unvaccinated, 89.

The proportion of unprotected children in the schools is next given.

1. In country schools; children from three to fourteen years, 13·4 per cent.

2. In metropolitan schools; 5·2 per cent.

3. In Jews' schools; 6 per cent., or 1 in 166.

Finally, with regard to the computed sickness and mortality from small-pox, Mr. Marshall believes that

"For every 4191 children living between the ages of three and fourteen, belonging to the lower classes of society in London and the country together, 886 cases of sickness from small-pox and 138 deaths must at some time or other have occurred, the per centage of sickness being fifteen and three-quarters, and of deaths three and one-fifth in the whole number of children increased by adding the deaths.

"The Jews of Houndsditch and the Gentiles of Tothill-fields form a correct and instructive case for comparison. They alike reside in crowded houses and apartments, and alike belong to the lowest ranks of their respective denominations. The former, however, have only five and a-half per cent. of their children unvaccinated, whilst the latter have as many as thirty per cent. The proportionate risk in the case of the two is, therefore, as one to five,—and it will be found that the Jewish children of the East have suffered by sickness and mortality from small-pox, as compared with their less carefully protected brethren of the West, exactly in the same proportion of one to five."

Mr. Marshall's letter contains statistics founded on careful inquiry and laborious personal investigation. For this reason, and because of the valuable suggestions contained in his pamphlet, we recommend it to the consideration of all who are interested in the promotion of effectual legislative measures for the extension of vaccination.

THE CLIMATE OF SIDMOUTH. By W. H. CULLEN, M.D.
Sidmouth: 1852.

As the science of meteorology, assisted by statistics, advances, the importance of a native climate, in the relief of pulmonary consumption and other cachectic maladies, will become more and more investigated. This can only be properly performed by a series of long continued observations, made by various observers; so that, while we are bound to praise all such efforts to make the profession more acquainted with the peculiar characteristics of particular localities, we are equally compelled to remove them from the category of mere book-making treatises. The investigation of foreign climates, to which alone, a few years since, all the benefit presumed to be derived in pulmonary cases was attributed, has revealed to us that many of the more lauded situations present unfavourable results when compared with many native regions. Dr. Turnbull, of Liverpool, in his recently issued work *On the Progress of Improvement in the Treatment of Consumption and other Pulmonary and Laryngeal Diseases*, makes the following apposite remarks on this subject:—

"It has been ascertained that consumption is a very common disease among the resident inhabitants of many of those places, to which invalids from this country resort. The selection of a suitable climate is a subject which could not be briefly touched upon with advantage; I shall only, therefore, observe, that the change to more distant places is adapted chiefly to those in whom tubercular disease is in an early stage, or very perfectly arrested; and that most of the advantages of change may be more safely attained by more delicate invalids by removal from one part of this country to another."

How important, then, is it, that we should endeavour to discover the means of cure presented by various localities in the British islands, and that the experience of observers like Sir James Clark, Dr. Forbes, Dr. Shapter, Dr. Granville, and others, should be brought to bear upon the con-

firmation of the concluding paragraph of Dr. Burgess' work on the *Climate of Italy* noticed in this Journal for Jan. 21.

"From the preceding summary of the characters manifested by the different Italian climates, it will be seen that, however useful they may prove in other complaints, one more likely to act beneficially in pulmonary consumption might easily be found within the United Kingdom."

The sheltered situation of the little town of Sidmouth, opening to the sea, protected from all obnoxious winds by the hills which, as it were, hem it in, enjoying the warm air of the south of Devon, has very naturally caused it to become one of the favourite localities for consumptive invalids. Dr. CULLEN, whose only fault is brevity—a great recommendation to a local work—has given us the result of the observations of a number of years, to prove that Sidmouth really deserves all that has been related of it. His comparative tables render his work extremely useful; and, as far as statistical deductions warrant the assumption, he proves that Sidmouth, if not the best, is at least one of those places to which a consumptive patient, under the circumstances mentioned by Dr. Turnbull, may be sent, with every prospect of benefit being derived.

We welcome Dr. Cullen into this field of investigation, and express the hope that he will ere long favour the profession with the result of his treatment of pulmonic cases, aided by the hygienic advantages of the climate of Sidmouth.

A NATURALIST'S RAMBLES ON THE DEVONSHIRE COAST.
By PHILIP HENRY GOSSE, A.L.S. pp. 448. London: 1853.

MR. GOSSE is well known to the student of nature by his *Ocean* and by his *Naturalist's Sojourn in Jamaica*. The present volume is a worthy companion to its predecessors. There is a great amount of information conveyed in an elegant and pleasing style; and the perspicuity of the descriptions is increased by a profusion of splendid illustrations. As a specimen of the book we quote a description of a capture made in the Barricane Pools.

"Among the animals was a creature of exquisite beauty, which I now saw for the first time. It was the CRESTED ANTIOPA, one of the naked gilled Mollusca, closely allied to the *Eolides*, some of which formed the subjects of observation in an earlier part of this volume. The breathing organs are very numerous; they consist of oval bags, delicately pellucid, arranged all round the sides and front of the animal, and have an extremely elegant appearance. Each one has a brown line running through its transparent substance, and is tipped with silver-white. The general colour of the animal is pellucid-grey, with spots and lines of opaque white; they have the lustre of silver. It is about an inch in length.

"This beautiful little animal I brought carefully home and placed in one of my large glass vases of sea-water, kept in a state fit for the support of animal life by growing sea-weeds. It immediately became at home in its new residence, and remained in good health for a considerable period. In about a week it laid on the side of the glass, just beneath the surface of the water, a beautiful coil of spawn, which looked like a necklace of white beads, arranged in successive furlongs, or figures of 8, in a spiral form, making just a coil and a half. A closer inspection showed that these folds were enclosed in a band of clear transparent jelly. A most beautiful object it was even when cursorily looked at; but when examined with a lens, each of the beads, which at first I had supposed to be the ova, was really a nidus of many; a perfect sphere of clear jelly contained about sixty embryos, arranged in crescent form in the globule, filling more than half its volume.

"Five days after the deposition I saw that the embryos were in rapid motion within their spherules. I therefore detached two from the gelatinous band, and placed them in a cell beneath the microscope. The little nautilus-like embryos were now seen each in his tiny shell of one spire, vibrating his cilia with energy, and all swimming rapidly among each other within their sphere seeking an outlet. The soft walls yielded and protruded here and there as one and another pressed forcibly against them, and at length burst, and the embryos came out as they discovered the breach.

"Taking sixty to be the average number of embryos in each spherule, I endeavoured to estimate the total number in this

coil of spawn. I found about twenty-five spherules in each figure 8, which gives 750 embryos: then there were about thirty convolutions in the whole coil, which gives the total 45,000 embryos. Yet this coil was not all the spawn perfected by this animal in the season, for a large contorted roll is yet visible in the ovary, through the pellucid body of the *Antiopa*: and these creatures are well known to lay their spawn at short intervals all through the season." (pp. 325-327.)

Lovers of natural history will find Mr. Gosse's pages full of curious and entertaining knowledge. "They contain," says the author in his preface, "a faithful record of what actually has fallen under an individual's observation in a single season, and may therefore be assumed to present a fair average of what may be expected again."

OBSERVATIONS ON THE NATURE AND THE TREATMENT OF ASIATIC CHOLERA. By WM. STEVENS, M.D., D.C.L. Oxon. pp. 499. London: 1853.

THE object of this work is to defend the saline treatment of cholera. We regret that we have not space at our command to critically examine its contents. We cannot, however, do less than say that it is the production of an able, truth-seeking mind, and calculated to instruct even those who deny, as well as those who adopt the theory and treatment which it so earnestly advocates.

PATHOLOGICAL AND PRACTICAL TREATISE ON EPIDEMIC CHOLERA, its History, Causes, Various Forms, and Treatment. pp. 184. London: 1853.

THIS is a very sensible little work: but like everything which has been written on cholera, it is as well calculated to raise disputed questions, as to settle the pathology and treatment of the disease.

PERISCOPIC REVIEW.

MATERIA MEDICA, PHARMACY, AND THERAPEUTICS.

STRINGFELLOW'S GALVANIC BATTERY.

WE received, some weeks ago, one of these machines from the inventor, and have now much pleasure in reporting upon it. STRINGFELLOW'S arrangement is the most perfect for physiological purposes which has ever been contrived. In size it does not exceed a lady's card-case. Its principle is the same as Pulvermacher's chain; but it is more effective and energetic, on account of

FIRST. The very small obstruction offered to the passage of the current, from the perfect connexion of the metallic elements, instead of their being hung on loops;

SECOND. The large extent of the generating or electro-positive element, and its very close proximity to the conducting or electro-negative element; thus reducing to a minimum the opposition offered to the current flowing through the exciting fluid;

THIRD. The extreme compactness of the apparatus; twenty-two compound elements entering, after being excited, into a common card-case, and evolving a current capable of decomposing water, and giving smart shocks for nearly half an hour; evaporation being prevented by the ingenious plan of inclosing the battery in a card-case.

The remarkable fact connected with this battery, of four elements, moistened with water only, being capable of decomposing distilled water, is worth attention, and can only be explained by the almost complete absence of all opposing causes interfering with the passage of the current; hence, all the electricity excited is thrown into current, and none lost; whereas, in some pieces of apparatus of this kind, a great quantity is lost.

THE PRESERVATION OF LEECHES.

As a general rule, leeches should not be kept in the shop or laboratory, because these places are frequently pervaded with the vapours of ether, acids, and ammonia. It is advisable to place them in a cellar where no drugs or chemicals are kept. I recommend leeches to be kept in large stoneware pots, supplied

with pure spring water. When cleanliness is observed, they can be preserved without any particular loss, and never require turf, calamus root, or charcoal.

I employ the following simple method of treatment:—I always keep one or more leech-pots than I require for use; these duplicates serve for changing. If in one pot a particular mortality is exhibited, the colony of leeches is removed into a clean pot, after having been well washed. The unhealthy pot is purified; with a brush and sand all the slime is rubbed and washed from its walls; then some chlorine water is poured in, and allowed to remain in the covered vessel several hours. The chlorine water is removed, the pot filled several times with fresh water, allowed to stand, and poured off. The vessel is now dried in the air, and if possible in the sun. In this manner all infectious matters are removed or destroyed, and the healthiness of the jar again restored. However, there are cases where nothing avails, as the leeches are sick when received.

Wooden vessels often remain long healthy, but when they once become foul, it is almost impossible to cleanse them. The pots should be covered with thick linen. Sometimes, nevertheless, leeches get through and disappear. As they run over woollen cloth reluctantly, it is advisable to bind a strip of cloth round the outside of the pot. Some pharmacists keep leeches in open jars, the mouths of which are surrounded with cloth, as they never escape under these circumstances. (Dr. MORRIS in *Pharmaceut. Technik. Zweite Auflage*, as quoted in *Annals of Pharmacy*.)

PRACTICE OF MEDICINE AND PATHOLOGY.

PLEURO-PNEUMONIA IN CATTLE: INOCULATION.

Dr. WILLEMS, of Belgium, recently announced, that he had discovered the means of greatly reducing the mortality from pleuro-pneumonia, if not of entirely arresting its progress, by inoculating healthy animals with matter from the lungs of one that had died of the disease; and very extensive experiments have been made to test the reality of the remedy. Professor Simonds, of the Veterinary College, having been deputed by the Royal Agricultural Society to investigate the supposed discovery, and having visited Belgium, and made extensive inquiries on the subject, has made his report, from which it appears that the prevention of pleuro-pneumonia by inoculation is, to say the least, doubtful. In 1850, Dr. Willems having failed to arrest the disease by medical treatment, tried inoculation as an experiment, and has convinced himself of its success. The practice, too, is becoming general throughout the kingdom. A Dr. de Salve also has been extensively engaged in inoculating cattle in Rhenish Prussia, but with such ill success that the Government has ordered inoculation to be discontinued. The Belgian Government, however, takes a lively interest in the subject, and has instituted a series of experiments, which probably ere long will decide the question as to the value of the practice of inoculation. The disease produced by inoculation is said to be local only, and not to affect the lungs, the seat of the natural distemper. "About two per cent.," says Mr. Simonds, "of the inoculated animals die, while a far greater proportion suffer from ulcerative and gangrenous inflammation of their tails; notwithstanding which, their lungs, the local seat of the natural disease, we are assured, never suffer. If experience proves this to be true, it must be regarded as a new fact in medicine." And he mentions that, in 1757, Dr. Layard, a celebrated physician of that day, wrote an essay, recommending the inoculation of cattle to prevent deaths from a destructive malady which then prevailed in this country. Some distillers in Hasselt, who objected to inoculation, had their cattle-sheds quite free from the disease; and, while inoculated animals placed among a diseased herd are stated to have escaped, there have also been others, non-inoculated cattle, in the same situation, which have been equally exempt. Dr. Willems does not admit a single failure of inoculation; but, from other persons, Mr. Simonds received very contradictory accounts. To himself, none of the operations he witnessed appeared to be satisfactory. With the aid of several members of the Royal Agricultural Society, Mr. Simonds is about to undertake experiments in this country, in order to test the value of inoculation as a preventive of pleuro-pneumonia.

TREATMENT OF TYPHOID FEVER BY THE INTERNAL USE OF TINCTURE OF IODINE.

The *Bulletin de Thérapeutique* for March 30th states that M. ARAN has successfully treated several patients labouring under typhoid fever, in the hospital of La Pitié, with five-drop

doses of tincture of iodine, administered from three to six times in twenty-four hours. At the commencement of the attacks of fever in this epidemic, constipation occurred, and lasted several days; it was then followed by obstinate diarrhoea, which continued often some time after the patient had become apparently convalescent.

The effect produced by the tincture of iodine was on the tongue and abdominal organs, but especially on the diarrhoea. The tongue, from being dry and even rough, became moist; the abdomen became soft and painless; and the number of stools diminished from ten or twelve to two or three in twenty-four hours; in some cases, they entirely ceased.

Eight patients in different stages of fever were treated in this way. Only one died, after having been in an adynamic state for three or four days. The other seven rapidly became convalescent; and in one the medicine appeared to have stopped vomiting, which had harassed him from the commencement of his illness. All these patients had previously been treated by moderate blood-letting, emetics, purgatives, cold baths, or cold affusions.

The tincture of iodine is given on a piece of sugar, or in a little syrup. In most patients, it produces neither disgust, nausea, nor vomiting, nor any symptom indicative of an injurious action on the digestive organs.

EMPIRICAL TREATMENT OF CHOLERA IN CANADA.

"Do you know his famous remedy?" "Do I not? Did he not cure me when I was at the last gasp? Why, he makes no secret of it. It is all drawn from the maple-tree. First, he rubs the patient all over with an ointment, made of hog's lard, and maple-sugar, and ashes from the maple-tree, and he gives him a hot draught of maple-sugar and ley, which throws him into a violent perspiration. In about an hour the cramps subside; he falls into a quiet sleep, and when he awakes he is perfectly restored to health." Such were our first tidings of STEPHEN AYRES, the cholera doctor (1832), who is universally believed to have effected some wonderful cures. He obtained a wide celebrity throughout the colony. (*Moodie's Roughing it in the Bush*.)

CROTON-OIL IN DROPSY.

In the *Gazette des Hôpitaux* for May 14th, it is stated that M. NONAT, of the Hôpital de la Pitié, in Paris, gives croton-oil in dropsies arising from affections of the organs of circulation and respiration; or even when, without dropsy, there is an affection of the heart producing dyspnoea, cyanosis, and more or less severe general disturbance. The quantity administered is two drops, which are taken in the morning in two pills, with the interval of an hour between them.

Under this treatment, M. Nonat has seen ascites, extensive anasarca, palpitations with cyanosis, and severe dyspnoea, disappear in from a fortnight to a month. This treatment seems to him more efficacious than that by diuretics, digitalis, etc. He finds it advantageous to produce from ten to twenty serous stools, and to withhold drink from the patients, so that they lose much fluid while they take in little. The purgation is repeated every two or three days, according to the strength of the patient.

M. Nonat says that croton-oil must not be administered in dropsy dependent on structural disease of the kidneys or abdominal organs.

TREATMENT OF TENIA BY PUMPKIN-SEEDS.

The following is the substance of an article in the *Revue Médicale*.

Among the remedies which may be advantageously substituted for kouso in the treatment of tenia, the seeds of the pumpkin have perfectly succeeded in the hands of MM. BRUNET DELAMOTHE and MARTIGNY. The patient is ordered to take in the morning, fasting, ninety grammes (3ij) of a paste made with fresh pumpkins; and, an hour after, two ounces of honey, which is twice repeated at similar intervals. It is said that under this treatment, the tenia has always been expelled in the course of six or seven hours.

[The point to be ascertained with regard to the many vaunted remedies for tenia, is not so much whether they cause the expulsion of large portions of the worm, as whether they entirely dislodge it.]

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 10TH, 1853.

JAMES COPLAND, M.D., F.R.S., President, in the Chair.

FURTHER RESEARCHES ON THE PATHOLOGY OF PHEGMASTIA DOLENS. BY ROBERT LEE, M.D., F.R.S.

UNTIL the publication of the memoirs of M. Bouillard, M. Velpeau, and the late Dr. Davis, various hypotheses had been advanced respecting the cause of the swelling in the lower extremities of puerperal women; but the cases and dissections of the authors just enumerated demonstrated that the true nature of the disease consisted in an inflammation of the trunks and principal branches of the veins of the lower extremities. In papers by Dr. LEE, published in the fifteenth volume of the *Medico-Chirurgical Transactions*, the actual condition of the iliac and femoral veins was ascertained; and he had been led to infer that inflammation of these veins gave rise to the phenomena of phlegmasia dolens, and that it commenced in the uterine branches of the hypogastric veins, and extended from them into the iliac and femoral trunks. Other cases had been recorded in the *Transactions*, of crural phlebitis following ulceration of the mucous membrane of the intestines. Experiments performed by Pirigoff in 1839, and by Reumert in 1840, on dogs, showed that the action of chemical and mechanical irritants was limited to the vein on which the experiment was made, and the extension of the inflammation in the veins was not common; and Stannius, who had collated and tested all the facts bearing on the subject, doubted whether inflammation of venous trunks admitted of being excited by constitutional causes, independently of local irritation. A series of experiments on the veins of the lower animals had recently been made, and a paper on phlegmasia dolens had been read to the Society during the present session, not founded on actual observation of the disease as it occurs in the human subject, but upon experiments on the veins of the lower animals, in which phlegmasia dolens had never been observed.* The object of the present communication was to submit to the Society the observations which the author had made during the last twenty-four years, on inflammation of the crural veins. The paper contained the record of forty-three cases of phlegmasia dolens. The first nine cases were accompanied by *post mortem* descriptions, and preparations illustrating the disease; and the author was led to the conclusions, "that inflammation of the iliac and femoral veins gave rise to all the phenomena of phlegmasia dolens, and that the inflammation commenced in the uterine branches of the hypogastric veins, and from them extended to the iliac and femoral trunks of the affected side." The next series comprised the history of twenty cases, which, the author thought, furnished additional evidence in favour of this conclusion, though, in consequence of the recovery of the greater number of the patients, an opportunity was not afforded of determining by dissection the actual condition of the crural veins. Nine cases followed, which, Dr. Lee thought, demonstrated that phlegmasia dolens might occur wholly unconnected with pregnancy and parturition, and that in such cases the inflammation likewise commenced in the uterine branches of the hypogastric veins, and followed a course similar to what occurred in puerperal cases. In some of these, the inflammation of the uterine veins was produced by cancerous disease of the os and cervix uteri; in others, there was no organic disease of any kind previously existing. The concluding cases were five, in which crural phlebitis had followed inflammation of the saphena veins, and of the deep veins of the lower extremities, from fracture of the tibia and fibula, and the pressure of encephaloid tumours on the thoracic viscera. The author thought that these cases and dissections, as well as those of the authors whom he had quoted, proved that inflammation of the iliac and femoral veins was the proximate cause of phlegmasia dolens; and that in puerperal women this inflammation commenced in the uterine branches of the hypogastric veins. It had likewise been demonstrated that phlegmasia dolens might take place in women who had never been pregnant, and even in the male sex; and that, under all circumstances, the proximate cause was the same.

Mr. MAYO wished to know whether Dr. Lee had ever observed any symptoms that might be regarded as antecedents in the

cases of phlegmasia dolens, which he had witnessed, such as general plethora, a loaded state of bowels, etc.

Mr. STREETER inquired whether Dr. Lee was provided with any statistical accounts respecting the frequency of phlegmasia dolens, whether following parturition or not connected therewith.

Dr. JOHN CLARKE believed that the concurrent testimony of numerous authors proved that phlegmasia dolens was a disease rarely fatal. Now, it was well known, that crural phlebitis was a very dangerous affection, not infrequently followed by death; and he was, therefore, disposed to believe that, if phlegmasia dolens did in reality always commence with inflammation of the iliac and femoral veins, it would be a much more dangerous malady than they had hitherto been accustomed to regard it.

Dr. MACKENZIE said that it was important to distinguish between alleged facts and the conclusions drawn from them. In the present case, the facts alleged were, that certain lesions of the crural veins were developed in the progress of phlegmasia dolens: the conclusions were, that such lesions constituted the essence or proximate cause of the disease. He assented entirely to the first of these propositions, while he dissented as entirely from the latter. The disease known as *phlegmasia dolens* was a very complex malady. It was characterised, not only by a morbid condition of the veins, but also by a morbid condition of the sensory, the motor, the lymphatic, and the secretory organs of the affected extremity; and, accordingly, in all well-marked cases, there was exquisite sensibility of the limb, especially in the track of particular nerves, loss of motor power, amounting sometimes to perfect immobility of the extremity, inflammation and obstruction of the lymphatic vessels and glands, and a general hot, tense, and elastic swelling of the limb, possessing rather the character of active exudation than of passive effusion. Could all these lesions be deduced from mere inflammation and obstruction of the principal vein of the extremity? Were they ordinarily observed in cases of simple, uncomplicated phlebitis? Or was there anything in the anatomical or physiological characters of the veins to justify our deducing them *a priori* from it? And have those who adopt this theory reproduced the lesion of the veins in a simple uncomplicated form, and observed such consequences to follow? To these questions we must reply in the negative: and the whole matter rested purely on assumption. It had been assumed, that because the crural veins were found obviously diseased in fatal cases of phlegmasia dolens, such lesions constituted the proximate cause of the disease; but this had not been made a matter of demonstration. Further, the clinical history of the disease and the progress of symptoms did not support this theory. It was quite true, that in some cases the irritations commenced in the region of the femoral vessels; but in some they commenced in the back, in others in the hip, sometimes in the calf of the leg, and more frequently in the popliteal region. Again, one leg might be affected alone, or both lower extremities concurrently; or the disease, after having attacked one, might pass on to the other, or a superior extremity might be affected; and Dr. Mackenzie had lately met with a case in which, after symptoms of the disease had successively declared themselves in the left lower and upper extremities, the malady ultimately established itself in the right arm, the whole right upper extremity being hot, swollen, and tense, the surface exquisitely painful, with loss of motor power, and a tense, corded condition of the basilic vein. These facts pointed to some more general and diffusive cause, in regard to which it was probable that phlebitis itself was but a secondary affection. The diversity of opinion which still existed, both in this country and on the continent, as to the nature of phlegmasia dolens, even since the promulgation of the phlebotic theory of the disease, afforded a powerful argument against this theory; because it tended to show that we could not thereby account rationally for all the known phenomena of the disease. Then, in the sequelæ of the disease, circumstances were met with which are inconsistent with this theory. After an attack of the disease, the crural veins are generally left impervious, and yet successive attacks may occur in the same extremity. So also it happened after an attack of the disease, that the limb would be left for many years, or even for the remainder of life, in a weak, sensitive, and irritable condition, being easily affected by atmospheric and constitutional influences. It was easy to reconcile these facts with the notion, that the nerves had been injured or damaged, but not with the idea that the veins alone had been affected. On all these grounds, then, it appeared to him (Dr. Mackenzie) that the phlebotic theory of the disease was either defective or erroneous. But, assuming for a moment that it was correct, it left much

* Vide ASSOCIATION MEDICAL JOURNAL, March 25th, 1853.

which was still to be explained. We had yet to learn the nature of that peculiar inflammation of the veins met with in this disease, which was so different from ordinary phlebitis. Did it depend upon some peculiar disposition on the part of the venous coats to take on diffusive inflammation, or did it depend primarily upon the blood? If we adopted the first of these theories, we were bound to state the nature of the peculiarity, and the laws of its development. If, on the other hand, we regarded the venous inflammation as dependent upon some morbid condition of the blood, then we might reasonably account, not only for the peculiarities it presented, but for the lesions of other organs, and the structural changes, with which it was associated. Upon this view, also, we might reconcile the conflicting opinions which had been held by different pathologists, and the variations which the disease manifested in its symptoms and progress in different cases. In accepting this view, we must forego the theory that phlebitis was the proximate cause of the disease, and regard it, as it really was, as a phenomenon related to the other lesions of the extremity, not so much in the order of cause and effect, as in being, like them, a parallel effect of some more general and diffusive morbid agent.

Dr. LEE, in reply, gave an historical account of phlegmasia dolens, from the time it was first pointed out by Mauriceau up to the present day.

JAMES COPLAND, M.D., F.R.S., President, in the Chair.

ON THE USE OF TWO NEEDLES AT ONCE IN CERTAIN OPERATIONS ON THE EYE, ESPECIALLY IN THOSE FOR CAPSULAR CATARACT AND ARTIFICIAL PUPIL. BY WILLIAM BOWMAN, ESQ.

The operation consists in the simultaneous employment of two needles introduced at different points through the outer coat, and made to act in concert upon false membranes, opaque capsule, or iris, or even on the lens itself under certain circumstances. Several advantages attend this mode of operating. Opaque portions of capsule are often very tough, and, being attached to the suspensory ligament of the lens, or to the pupillary borders of the iris, these extensile structures readily allow the opaque membrane to recede before the needle, rather than be torn or cut through; and the surgeon vainly sweeps the membrane before the instrument from side to side, at the risk of serious injury, and consecutive inflammation of the ciliary processes or iris. Two needles, brought to bear upon the opaque capsule from different sides of the cornea or sclerótica, furnish each other with a point of resistance, and the capsule may be torn open or cut at pleasure. If it be reticulated, it is possible to twist one of the needles round and round the band, so as to get a hold upon it in case it should prove very tough. The needles usually act perfectly if passed through any convenient opposite points of the margin of the cornea, the pupil being always, where possible, dilated by atropine. It is but seldom desirable that one of the needles should be passed through the sclerótica. The lids must be held open, either by an assistant or by the wire speculum. The second needle may be in cases where the first, or single needle, has failed to cut through the capsule. The instruments are the ordinary cataract needle, the stem cylindrical, and of a size to easily occupy the corneal puncture, the point either straight and cutting, or slightly curved, according to circumstances. In no case is it necessary to enter the instrument beyond half an inch in depth; the stem may therefore be made thicker from this distance. This plan of operating enables the surgeon to cut through a softened iris, without dragging it from its attachment, and otherwise injuring the interior of the globe. Mr. Bowman has used it successfully in the formation of artificial pupil.

ANALYSIS OF THE CASES OF INJURIES OF THE HEAD EXAMINED AFTER DEATH IN ST. GEORGE'S HOSPITAL, FROM JANUARY 1841, TO JANUARY 1851; WITH PATHOLOGICAL AND SURGICAL OBSERVATIONS. BY PRESCOTT HEWETT, ESQ.

In this analysis the author included only fatal cases where the exact nature of the injury had been clearly made out.

I. SCALP WOUNDS WITHOUT FRACTURE OF THE BONES. In this decennium, thirty-three cases of scalp wounds without fracture of the bones were examined. In ten of these cases death was produced by some other cause. In the remaining twenty-three cases mischief of a serious nature soon followed the injury, and ultimately proved fatal. Diffuse cellular inflammation occurred in seventeen cases; and in twelve this was accompanied with erysipelas. In four cases there was diffuse in-

flammation of the neck, which spread down to the mediastina in two, and caused oedema of the larynx in two cases. Hemorrhage in two cases followed sloughing caused by inflammation. In nine out of twelve cases, where both brain and its membranes were healthy, death ensued from purulent infection. In ten cases, inflammation had existed about the membranes or the brain. In eight, suppuration was found between the bone and the dura mater. The trephine had been applied in three cases. Most of the patients were persons of intemperate habits. Several had insisted upon leaving the hospital, but were readmitted with swelling of the scalp and other signs of inflammation. Simple puncture, as recommended by Sir Benjamin Brodie, relieves the oedematous swelling not uncommonly following scalp wounds; but free incisions are required when suppuration ensues. Sloughing of the scalp is thus usually prevented. Separation of the dura mater from the bone may occur either as a primary or as a secondary effect. In the first case, the small vessels connecting the dura mater to the bone are ruptured by the blow; in the second, the osseous tissue inflames and suppurates. Generally speaking, the suppuration between the bone and dura mater is circumscribed, and the extent of the mischief on the inner side of the bone is exactly traced by that on the outer side; but suppuration in the parietal region may be much more diffuse. In this decennium there had been no single instance of the secondary puffy tumour of the scalp described by Pott. It had never fallen to the author's lot to witness a case in which the application of the trephine for the evacuation of pus within the cranium, as described by Pott, had a successful issue. He had never known the trephine applied at St. George's Hospital, to evacuate matter situated either under the dura mater or in the brain. Matter may flow, upon the application of the trephine, from the cancellous diploe of the cranium. Purulent infection was observed in fourteen out of twenty-three fatal cases of scalp wound. This disease is found especially in injuries involving the osseous system, and M. Chassaignac believes that the removal by the trephine of the contused bone, before suppuration has taken place in its diploe, destroys the source whence the secondary mischief is for the most part derived; but such an explanation cannot be received as valid.

II. FRACTURES OF THE BONES AND SEPARATION OF THE SUTURES. In this decennium, seventy-eight cases of fractures of the skull were admitted, eighteen of which had received other severe injuries, of a nature likely to cause death; fifty-six were simple fractures; twenty-two were compound. Of the simple fractures, nineteen were accompanied by wounds of the scalp not exposing the bone; extensive separation of the sutures coexisted in fourteen cases. In forty-seven cases the injuries had been produced by the patients having fallen from various heights; in ten the blow had been inflicted by some heavy instrument. In the fifty-six cases of simple fracture, there was only one instance in which the injury was confined to the spot upon which the blow had been struck. Fractures of the base of the skull seldom exist alone; in a large majority of cases the injury co-exists with fractures radiating from the point where the blow was struck. In sixty-eight cases of fracture of the base, six only were confined to this region: and only in two cases no trace of fracture could be detected at the seat of the blow. In six cases of simple fracture, the injury was accompanied by depression, which was in all very slight. In ten cases of compound fracture there was also depression of the fragments, considerable in nine. Fractures of the skull, with depression of the inner table alone occur but rarely. The author divided the skull into three zones, to each of which injuries are often confined, fractures of the middle zone being the most common. Fractures involving the orbital plates of the frontal bone are often accompanied with effusion of blood into the orbit. Bleeding from the ear is not infrequent in severe injuries to the head, indicating fracture through the petrous portion of the temporal bone. But of the signs indicative of fracture of the petrous bone, one of the surest is the copious discharge of a watery fluid, which may or may not be preceded by bleeding. The author believed the fluid to come from the sub-arachnoid space. That such is sometimes the case had been established by M. Robert, in a valuable paper in the *Mémoires de la Société de Chirurgie de Paris*, vol. i. The discharge occurred in old as well as in young subjects. M. Chassaignac had endeavoured to prove that this fluid owes its origin to the filtering of the colourless part of the blood, and other surgeons had held that it comes from the cavity of the arachnoid. Such cases, however, if they do occur, must be rare. The author did not believe that the source of the watery fluid in all cases is the sub-arachnoid space, but that it was in most cases, and especially in those where it is clear and abundant from the commencement. Extensive separation of the sutures

co-existed with the fractures in fourteen cases; separation of the coronal suture occurred in seven cases, and of the lambdoidal in three cases; of the sagittal suture in four cases. In one case only, there was separation of a suture, without a fracture, in the posterior part of the squamo-parietal suture.

Dr. COPLAND was surprised that, amongst so many cases, there had been so few in which the effects of injury to the head had been developed at a longer period after the receipt of the mischief. He alluded to the occurrence of abscess of the brain a year or so after the first effects of the injury had gone off.

Mr. HAWKINS said that very few instances could occur at the present day, in which the trephine should be applied to the vault of the skull for blood effused at the base, or for the removal of pus situated at a distance from the point at which the skull was perforated. Pus, or blood effused within the substance, would be less likely to be mistaken for pus, or blood effused exterior to the cerebral substance. All the cases related had been fatal; but it was possible for the head to suffer, without a fatal result, severe injuries, the nature of which might be diagnosed with considerable accuracy. He would mention two examples. A man was brought under his notice, whose head had been caught between the buffers of two railway carriages, and severely injured. He had profuse bleeding from the ear, and disorder of motion and sensibility in all the parts supplied by the nerves emanating from the base of the skull. In fact, there were unequivocal symptoms of fracture of the base of the skull. The man, however, slowly recovered, although it was some time before he was able to walk, and even now he was unable to see correctly with one eye. In the second instance, a woman suffered a severe fracture of the skull, extending, as the symptoms unmistakeably showed, to the base, consequent on her having been tossed by a bull. The patient was restored to health. The discharge of watery fluid would, he thought, now become an important symptom, in consequence of its indicating, as Mr. Hewett had shown, the line of direction which the fracture pursued.

Mr. CURLING thought that the interest of Mr. Hewett's paper would have been increased, had the author included cases of recovery. He had himself witnessed several instances of recovery, and it would be interesting to know in what proportion recovery occurred, as this circumstance might throw light on the views entertained of the origin of the discharge from the ear. He could confirm the observations of Mr. Hewett in respect to the existence of suppuration within the dura mater. In all the cases in which he (Mr. Curling) had seen the trephine used, pus was found within the dura mater as well as outside the membrane. The author had omitted reference to cases of *contre-coup*. He did not mean instances in which the fracture was opposite to the seat of violence, for they were very rare; but the more common cases of laceration of the brain, and extravasation of blood, occurring opposite to the part at which the marks of external violence were found. He considered the number of deaths from scalp wounds and diffuse inflammation as large, and he had remarked that in certain constitutions where injuries of the head were treated actively by bleeding and mercury, the results were less favourable than when more moderate measures were adopted.

Mr. PRESCOTT HEWETT had purposely left out of his paper all the cases which had recovered, because it was only when the patient died that we could determine positively the state of the fracture, its exact situation, etc. His observations with reference to the sub-arachnoid fluid had been the result of dissection. He had alluded to cases of *contrecoup*, though not to the particular class of this injury mentioned by Mr. Curling. The mortality of scalp-wounds might seem large, but he did not think it was so, recollecting the great number of cases of purulent infection which had occurred, and in which recovery would not have taken place under any treatment.

BIRMINGHAM PATHOLOGICAL SOCIETY.

T. BELL FLETCHER, M.D., in the Chair.

DURATION OF HUMAN LIFE VIEWED IN RELATION TO MORAL CAUSES. BY H. L. SMITH, ESQ.

Mr. SMITH's object was to show, that from the first ages to the present time, there has been a striking correspondence between the prevalence of mortality and moral depravity; and that this is too remarkable to be explained otherwise than by regarding it as the result of direct divine ordination. In illustrating his views, he employed two original charts; the one chronological, showing the periods of the ætymological plagues and pestilences;

and the other historical, in which was shown the periodicity with which, from the time of Adam to that of the Jewish Commonwealth, death advanced and life decayed.

Thus, the primal sin *disobedience* rendered Adam mortal; and he and his descendants, down to Noah, were restricted to an average life just within *one thousand years*. Violence then coming to prevail, the period was halved to five hundred years. This continued till the incoming of *pride* led to the erection of the Tower of Babel, and the further reduction of life to two hundred and forty years. Presently, *idolatry* and *lust* prevailed; and the duration of life was correspondingly lessened to an average of a hundred and twenty years. During the time the children of Israel were in the wilderness, a period of *hardness of heart* and *unbelief*, there were but two living, to pass over the river Jordan, of the six hundred thousand men who forty years before had passed over the Red Sea.

Thus, from Adam to Moses, life was shortened exclusively from moral causes. From these data, Mr. Smith drew the conclusion, that in proportion to the wrong doing of men and nations, will be the brevity of their lives; and that not so much in consequence of their sin, but as the result of a special divine arrangement. And he drew attention to the fact of the increased duration of life in the present day (as shown by insurance office tables), in connexion with the existence of a more elevated standard of morality. Having thus asserted the predominance of moral over physical causes in lengthening human life, he concluded by urging the claims of the subject on the attention of the medical profession, and of all those who are interested in studying the dynamics of life.

ASSOCIATION INTELLIGENCE.

TWENTY-FIRST ANNIVERSARY MEETING.

The Anniversary Meeting of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION will be held at Swansea, on Wednesday, the 10th, and Thursday, the 11th of August. The particulars were published in the JOURNAL for May 27th, p. 470; and it is intended to reprint them, with additions, in the numbers for July 8th, and August 5th.

ANNIVERSARY BRANCH MEETINGS ALREADY ANNOUNCED.

The following is a summary of official notices contained in our last number, to which we refer for details.

BRANCH.	DAY AND HOUR.	PLACE.
Lancashire and Cheshire.	June 29th, at 12 o'clock.	Town Hall, Manchester.
South Eastern.	Same day and hour.	Sussex Hotel, Tunbridge Wells.
West Somerset.	Same day, 2 P.M.	Castle Hotel, Taunton.
Bath and Bristol.	June 30th, 3 P.M.	Medical Library, Bristol.
Metropolitan Counties.	July 10th, 4 P.M.	Brunswick Hotel, Blackwall.

MONMOUTHSHIRE AND SOUTH WALES BRANCH: NOTICE OF ANNUAL MEETING.

The second Annual Meeting of this Branch will be held at Chepstow, on Wednesday, the 6th day of July, 1853; Trevor Morris, Esq., M.D., President.

The Council will meet at 12 o'clock, in the Public Rooms, Bank Buildings. At 2 P.M., the Anniversary Meeting will be held at the above Rooms, when the President will deliver an address. The officers for the next year will be elected. The Medical Reform and Vaccination Bills will be considered, and cases and communications read. At 5 P.M., the members and their friends will dine together at the Assembly Room, Beaufort Arms. Tickets £1:1:0 each.

Members arriving at Chepstow are requested to call on Mr. Morris, Welsh Street, who will be happy to afford them local information.

W. H. MORRIS, M.D., President.

THE CONSTITUTION, LAWS, AND FINANCES OF THE ASSOCIATION:—COMMITTEE OF INQUIRY TO BE PROPOSED AT SWANSEA.

LETTER FROM DR. CORMACK TO SIR CHARLES HASTINGS, M.D.,
PRESIDENT OF THE COUNCIL OF THE PROVINCIAL
MEDICAL AND SURGICAL ASSOCIATION.

Patney, June 16th, 1853.

MY DEAR SIR CHARLES,—It is important that my intention of moving the following resolutions at the Swansea meeting should be known to all the members of the Association; and as the most proper method of accomplishing this object, I address to you this note, that it may obtain circulation as an official document.

The following are the resolutions which I intend to propose.

I. That a Committee be appointed to report to the Anniversary Meeting in 1854, upon the Constitution, Laws, and Finances of the Association.

II. That the following constitute the Committee:—

The President of the Association.

The President-Elect.

The President of the Council.

The General Secretary of the Association.

The Presidents of all the Branches now in office.

The Secretaries of all the Branches now in office.

With power to add twelve to their number.

III. That the Treasurer be authorized to pay to this Committee £30 for its necessary expenses.

IV. That the first meeting of the Committee be held [*to-day or to-morrow, as may be agreed, at o'clock.*]

If the Committee were appointed on the first day of our meeting, it might on that or the following day assemble for the purpose of electing the twelve additional members, in accordance with the suggestions of our colleagues. It is important that all who accept office in this Committee be prepared to devote themselves with earnestness and assiduity to the difficult questions which must come before them.

In proposing the resolutions, I shall endeavour to give a short but comprehensive outline of the principal subjects which are likely to engage the attention of the proposed Committee. At present, I am anxious to state that the three main questions seem to me to be—

FIRST. An improved constitution in the Executive Council, so as to make it, to a large extent, a representative body, composed of members annually elected by the Branches.

SECOND. An expansion of the Branch system.

THIRD. The formation of some financial laws for the safe regulation of current expenditure; and for the establishment of a reserve fund to prevent the Association being at any time crippled by such fluctuations in income, as are inseparable from the career of such an institution as ours.

I am, my dear Sir Charles, yours with sincere esteem,

JOHN ROSE CORMACK.

EDITOR'S LETTER BOX.

SUNDAY AT THE CRYSTAL PALACE.

LETTER FROM DR. A. P. STEWART TO THE EDITOR.

SIR,—As a petition, signed by not fewer than six hundred and forty of the medical men of this metropolis, is about to be presented to the Houses of Parliament, I think you will agree with me that some account of its origin and object is due to the world. Its promoters have been charged, both publicly and in many private circles, with going beyond their province, with making an unwarrantable jumble of medicine and theology, and with insisting on a religious dogma, to the prejudice alike of physiological truth and the health of the working classes. We meet these charges with a general and unhesitating contradiction. We have not transgressed our province; but if we had, we were challenged to do so by our accusers; and, though resting our appeal for the maintenance of the existing law mainly on the sanitary requirements of the working classes, we felt bound at the same time to declare without reserve our convictions of what is due to religious truth and public morality.

Let me state, in few words, the history of the petition, which I hope you will be able to insert entire.

Those who are interested in the opening of the Crystal Palace at Sydenham on Sundays, considering that their other arguments would be strengthened if they could enlist the support of the medical profession, sent petitions to all or most of the hospitals and dispensaries in London, (and one, I understand, was stealthily laid on the table of the Royal Medical and Chirurgical Society,) requesting signatures in favour of the proposed measure. In some quarters, this application was more or less favourably received; in others, it was rejected with unqualified and unanimous reprobation. Several signatures having been attached to the petition at the Middlesex Hospital, those who decidedly disapproved of it felt bound to accept the challenge thus addressed to them *from without*, and fully as well as fearlessly to express their opinions on a subject of so great importance. Had they declined it, they would have laid themselves open to the just imputation of time-serving, and (let me add) cowardly unfaithfulness to their most sacred convictions of duty. Finding that many of their friends most heartily concurred in their views, and desired an opportunity of expressing them to Parliament, they resolved that the petition should embrace the whole of London, so far as it could be reached by them; and also that, as the movement had spontaneously originated within the pale of the medical profession, it should be, as it has been, carried on and completed solely by its members. It was not at first expected that it would receive more than fifty or a hundred signatures, but six hundred and forty-one have appended their names, among which are many of very high professional and scientific celebrity. Many others are at one with them on the question at issue, but object to signing petitions not strictly professional. Woe worth the day, when the lips of the medical man shall refuse to utter that noble sentiment, "*Homo sum, nihil humani à me alienum puto*".

The innovators demand the repeal of the existing law, which forbids the opening of places of amusement on Sunday for gain. The connexion between the health of the people and the pecuniary gains of a powerful trading company is by no means self-evident; yet, but for the tempting profits, we should have heard but little of the public health. The petitioners, on the other hand, plead for the maintenance of the existing law, on the ground that a seventh day of rest is essential to the well-being of ALL men in every condition of life. They condemn the system, yearly gaining ground, which, in the name of a portion of society, denies to many what God in his sovereignty and mercy designed for ALL—a seventh day of spiritual improvement and bodily repose. They see with alarm the statement, that the demands of cupidity, amusement, and vice—of the newspaper press, the canal, the steamer, the railroad, the public carriage, the tavern, the bakehouse, and the tobacco-shop, have already engulfed in the ever widening vortex of Sunday traffic nearly a million of the working men of Britain! If these human machines were beasts of burden, we might have some hope of bettering their condition under the act for the prevention of cruelty to animals; but as they are only men, gifted with reason and with deathless souls, they are to be sacrificed for the good of society—used up with appalling rapidity—compelled, for the sake of their fellows, to do harder work on the day of rest than on any other day of their toilsome week—doomed, as an omnibus-driver once said to a friend of mine, to look for rest only in their graves. Is this, we ask, in accordance with sound physiology, with ordinary humanity, above all, with Christian morality? Yet this is the system to which it is proposed, by the opening of the Crystal Palace on Sundays, to give a development hitherto unknown in England. We earnestly protest against it, not only on moral and economical, but "on sanitary and medical grounds", as "pregnant with disastrous results to the labouring classes", because we consider the sabbath rest essential to the health of ALL, and believe that, under the proposed relaxation of the law, the million of men now doomed to incessant toil would be quickly doubled. Then, if not before, the mass of the working classes would find, when too late, that, under a delusive expectation of increased facilities for healthful recreation, they had been sacrificed, in the first place, to "the claims of capital", and next, to the aristocracy of their own order and the middle classes, who can take their holiday when they please, without encroaching on the liberty of their more needy and helpless neighbours. We venture to think that the concluding paragraph of the petition, which pleads for a weekly half holiday to the labouring population, suggests "a more excellent way".

I am, etc.,

A. P. STEWART.

74, Grosvenor Street, June 20th, 1853.

The following is the Petition referred to by Dr. Stewart:—

To the Honourable the Commons of Great Britain and Ireland in Parliament assembled: the Petition of the undersigned Physicians, Surgeons, and General Practitioners, resident in London,

HUMBLY SHEWETH,—

That your petitioners, from their acquaintance with the labouring classes, and with the laws which regulate the human economy, are convinced that a Seventh Day of rest, instituted by God, and coeval with the existence of man, is essential to the bodily health and mental vigour of men, in every station of life.

That the system which provides for the gain of some, and the recreation, the amusement, and the vices of others, at the expense of their fellows, who require and are entitled to a day of rest as much as they, and thus consigns a large and yearly-growing proportion of the community to a life of unbroken toil, besides being at variance with that law of charity which enjoins us to do to others as we would they should do to us, has a direct tendency to undermine the health, exhaust the strength, and shorten the lives of those who are its victims.

That the proposal to open for profit the Crystal Palace, now in course of erection at Sydenham, and to create in connexion with it an enormous amount of railway traffic during a portion of the Lord's Day, lying manifestly open to these objections, and confessedly implying a still further extension of this hurtful system, appears to your petitioners pregnant with disastrous results to the labouring classes, because directly tending to defraud them of that boon, which the Sabbath-law of a beneficent Creator provides for the whole family of man.

That while they are more especially called to minister to the physical sufferings of their fellow creatures, your Petitioners cannot overlook the close relationship subsisting between moral and physical disease, or entertain the hope that any plans, which do not make full provision for their spiritual as well as for their physical necessities, will effect any great or permanent improvement in the health and the habits of the labouring population; and that, even if your Petitioners could altogether shut their eyes to the moral aspects of the above-mentioned proposal, in favour of which their opinion has been expressly invoked by its promoters, it would, according to their experience of the wants and slender resources of the labouring poor, be a mere mockery to offer the much needed blessings of health, fresh air, and recreation, at an expense far beyond the means of the vast majority, and sure to entail serious subsequent privation even on the few who might venture to incur it at distant intervals.

That your Petitioners, deeply sympathizing with the hard and cheerless lot of multitudes of their fellow-countymen, of whose health they may be considered in some sense the guardians, feel bound to protest against any encroachments, from whatever quarter they may come, on that day of rest which is the birth-right of the poor, and to claim for them far greater opportunities of healthful and innocent recreation than they now enjoy. Convinced that the present protracted hours of labour are not only hurtful but needless, and anxious to lighten instead of adding to the pressure of toil that now weighs so heavily on the working classes, your Petitioners desire to express their belief that the requirements of the Divine law, and the interests both of employers and artisans, may be harmonized by the concession, as in Manchester, and (to some extent) in Glasgow, of a portion of one of the working days as a weekly half holiday; and the provision, free of cost, in all the large towns of the United Kingdom, of Parks and Gardens, and of public Museums of Art and Science, fitted to elevate the habits and refine the tastes of the labouring population.

May it therefore please your Honourable House to refuse your assent to any measure calculated, in any way, to set aside the law actually in force and to legalize the opening of the Crystal Palace and its Grounds for gain on any portion of the Lord's Day.

And your petitioners, as in duty bound, will ever pray.

CHLOROFORM IN PARTURITION.

LETTER TO THE EDITOR.

SIR,—It is indeed true that we live in startling times; and it would seem that some members of the medical profession are determined we shall not be behind the rest of the world in a "go-ahead" progress. Your announcement, a few weeks ago, of the Queen's accouchement under chloroform, and that, under no other than ordinary circumstances, the royal child-birth had been treated by anaesthesia, doubtless gave rise to considerable

emotion and excitement both in the professional and the female world. I entertain too much sense of delicacy and respect for royal station, either to make unnecessary allusion to, or elicit a discussion upon the circumstances which induced the eminent medical attendants to administer chloroform; but it is a remarkable circumstance that, in the bulletins issued, not the slightest allusion to any untoward or unfavourable symptom in the royal patient is made. For some time, however, before this, it was well known that, in certain districts, the married—especially the young married—women, even of respectable society, had been in much agitation respecting the recent discussions upon chloroform, and had become so solicitous for its administration in their own cases, as to have sought for the attendance of such practitioners as had not entertained scruples as to its employment, but had found in this way a very ready and popular—though it may be questioned whether a very legitimate—introduction to obstetrical practice.

The effect of such a proceeding may be seen in a case which I will here relate.

I recently attended a lady, for the seventh or eighth time, in labour. The parturient process in this instance, as in every other in her case, was admirably illustrative of the accurate physiological and mechanical relations between the mother and child requisite for the production of natural offspring. The dilating and expulsive powers of the uterus were regular and effective. These actions, however, could not be had without pain; and in the midst of them she most importunately begged, and even insisted, to have chloroform given to her. To this request I declined acceding; and the mother and child were happily relieved in half an hour after the request was made, and within two hours from the commencement of labour.

This patient urged her wish to me, by telling "that Mrs. — and Mrs. — had taken it, and why should not she?" I apprehend that such a state of things in the practice of midwifery ought not to exist. I would ask, then, upon what new principles can this meddling or interference with natural labour be defended? Is it proper, in the normal condition of the female, to administer chloroform? Is it justifiable? I apprehend that every agent legitimately used in medicine is only for the alleviation or cure of disease, functional or organic. Will it be attempted to place parturition under the head of disease? No one, I conceive, will be so bold as to make that attempt.

Whence, then, comes the justification for this modern proceeding? I presume, from that inherent weakness in human nature, of shrinking from pain, and an eager desire to avoid all suffering, however legitimately enforced. To meet this desire, certain medical men have decided to lend their skill. But how does the question really stand? If labour be undeniably a physiological process for the birth of human offspring, and if anatomy and physiology have proved that this process cannot be obtained without fulfilling the Divine enunciation, "that in sorrow and pain woman should bring forth"; the whole of this being, notwithstanding, perfectly consistent with the health of mother and child,—what doctrine can be an excuse for mischievous meddling with such a miracle of contrivance? This, however, must be the obvious result—that, whilst the pains and perils of child-birth have always had a salutary moral influence on the female character, the interference proposed must have the opposite effect, viz., of seriously damaging the moral courage of parturient women, besides placing practitioners who object to such a procedure in embarrassment and difficulty.

In your own approval, by editorial remarks, of the regular use of chloroform, as well as in the result of Dr. Snow's experience in its administration and freedom from danger, as given in the number of the JOURNAL for June 10th, I do not observe a single ground of justification for interfering with perfectly natural labour; and it is easy to perceive, from the detail entered into by Dr. Snow in this matter, that, even under any circumstances, chloroform, like other agents on the living body, is irregular, and consequently may be very mischievous in its operation. Dr. Snow is not disposed to believe that the deaths which he relates—one in Dr. Ramsbotham's, and the other in Dr. Murphy's practice—were attributable to anaesthesia induced; but the question is, Could he say that death would have occurred had that not been practised? Those who have had a large amount of professional experience can testify to the very varied physical condition and temperament of parturient women, in whom there is not unfrequently a tendency to an abnormal condition of the heart and lungs. The indiscriminate use of chloroform in such cases must not only be mischievous, but often fatal. Besides, we can easily see the constant liability to danger from the regular use of chloroform in the lying-in chamber, especially in the enormous quantities stated by Dr.

Snow to be occasionally used—I presume in natural labour: and is it not likely to be a ready and quick means of self-destruction, eagerly seized upon by the unhappy woman, whose child-birth is only attended by shame and perhaps destitution?

What, then, is the course which ought to be pursued in this dilemma? The profession, as a commonwealth, is confessedly without any landmarks of polity or ethics by which to govern it; yet surely there is at this juncture an amount of character sufficient to defend the soundness of its position, and prevent it being "disturbed from its decent proprieties", although a flickering meteor may have moved over its horizon. From the example now given to the country by the medical attendants on royalty, every parturient woman in the realm will expect to be treated in labour by chloroform; and by the example thus set, great violence has been done to the judgment, the feelings, and the position of, I believe, many, if not the majority, of the best accoucheurs in the country. Is it not, therefore, incumbent on the teachers and examiners of midwifery in every school, especially in London, immediately to investigate the question in all its bearings, and to promulgate *ex cathedra* their opinions, both physiological and moral, on the subject, in order that as little time as possible may be lost in settling, by an amount of indisputable testimony, the scruples, the hesitations, and the doubts of the professional and the public mind. I am, etc.,

A MEMBER OF THE ASSOCIATION.

LORD LYTTTELTON'S VACCINATION BILL.

SECOND LETTER FROM EDWARD BARBER, ESQ., TO THE EDITOR.

SIR,—I do not question the good intentions of Lord Lyttelton in proposing his Vaccination Bill, but I doubt whether any of us are yet in a position to legislate for the suppression of small-pox. That its occurrence, subsequent to vaccination, is much more frequent now than it was twenty or thirty years ago, will, I think, be admitted by all who are of that standing in the profession; and my own observation leads me to the conclusion that within a much shorter period the protective influence of the vaccine virus has from some cause or other decidedly diminished. The subject is one in which hasty and crude legislation may do much mischief, and which presents many points necessary to be well considered before penal statutes are admissible. Amongst these are the points—whether vaccine virus taken directly from the cow is more effective than that which has been taken from a succession of human subjects; and if so, how long it may be used without reverting to the primary source, or rather, through how many of such subjects it may pass without materially impairing its protective influence; whether a scrofulous or other morbid diathesis diminishes the power of the virus; whether (as suggested in a former letter) infants of very tender age are less susceptible of the vaccine disease; and whether in them the constitutional effects are fully and perfectly produced, and the virus taken from them is as effective as that taken from children some months older; and if it be thought not to be so, what is the earliest age at which infants should be vaccinated to secure its full and effectual influence upon their own constitutions, and the transmission of a perfect and unimpaired virus to others? It should, if possible, be ascertained in what proportion of cases vaccination, duly and carefully performed, procures complete immunity from small-pox for life, and for how long a period it may on the average be relied upon in other cases. For, if its protective influence be only temporary (as it is believed in many cases to be), every measure must be defective which does not provide for general revaccination at stated periods.

For some years past it has appeared to me that small-pox, subsequent to vaccination, has been of more frequent occurrence than primary small-pox. It is the great difficulty we have now to contend with, and it is necessary, therefore, to consider whether time and circumstances may not have produced a modified form of the disease, for which the vaccine virus is not so effective an antidote as it has heretofore proved to be for the genuine small-pox, and if there be reason to think so, whether any and what protection can be given to the public against it. These are a few only of the points requiring careful investigation before the legislature can treat the subject of vaccination satisfactorily. In the meantime, perhaps, the utmost that can be done in the way of legislation is to impose restrictions and disqualifications upon the unvaccinated; for instance, exclusion of them and their families from charitable and public institutions of all kinds, from schools and public offices and employments etc., and from parochial relief: to enforce vaccination, and, if necessary, revaccination upon all tramps and vagrants, prisoners of

all kinds, and all who are brought into close contact with others whether in gaol or elsewhere, and to encourage it amongst the lower classes by rendering it as accessible as possible, and taking care not to identify it with parish relief. It seems vain to hope for any real improvement in the sanitary condition of the country, until such questions as the present, and indeed all questions affecting the public health, are submitted to the consideration and control of men whose attainments and pursuits give them the knowledge necessary to a proper handling of such subjects.

I am, etc.,

EDWARD BARBER.

Stamford, June 20th, 1853.

THE PENINSULAR AND ORIENTAL STEAM NAVIGATION COMPANY *versus* HER MAJESTY'S NAVY.

LETTER FROM HENRY BENCRAFT, ESQ., TO THE EDITOR.

SIR,—I entirely agree with you as to the importance of the Medical Department of the Navy; and I think that it is greatly to be deplored that the Board of Admiralty is so blind, as not to see that it is as much its duty, as it is necessary to the interests of the naval service, to endeavour to make the assistant-surgeon's position as agreeable as possible. In order to show you that this can be done at no very great sacrifice of money or convenience, I would beg to direct your attention for a few minutes to the manner in which our great steam navigation companies administer to the wants of their medical officers, and, indeed, do all in their power to make them feel that they are gentlemen, and that the office which they hold is one of great importance and responsibility. I am now speaking of the Peninsular and Oriental Steam Navigation Company, in whose service I spent two years prior to engaging in a country practice. My salary was one hundred pounds per annum, with living. I had a most excellent cabin—one of the best in the ship, with a roomy dispensary; the company finding all requisites and a servant to wait upon me. From the class of passengers carried by this great and liberal company, it is scarcely necessary for me to tell you, that in a sea-going ship the style of living could not be surpassed.

Now we all know that, with these trading companies, every foot of room is of considerable value; and yet the directors rate the surgeon's services so high that they liberally, without regard to the sacrifice of either space or expense, do all in their power to make him comfortable.

I would ask you, sir, is it not perfectly astonishing that the Board of Admiralty does not consider the lives of those brave fellows, who man "the wooden walls of Old England", of sufficient consequence to be cared for and protected, at least as efficiently as the Board of Directors of a carrying company care for and protect their passengers and servants?

I hope, sir, that ere long the voice of public opinion will cause this most foul blot to be removed from the national escutcheon.

I am, etc.,

HENRY BENCRAFT.

Swimbridge, near Barnstaple, Devon, June 14th, 1853.

NEWS AND TOPICS OF THE DAY.

THE AQUATIC VIVARIUM, REGENT'S PARK. On the borders of the flower-bed in the Zoological Gardens, Regent's Park, has been constructed, of glass and iron, a building sixty by twenty feet in area containing fourteen six-feet tanks of plate glass. Of these, six are ready for exhibition. They enclose masses of sand, rock, gravel, corallines, sea-weed, and sea-water; and are abundantly stocked with crustacea, star-fish, sea-eggs, actinias, ascidians, shelled, and shell-less molluscs, and fish of the genera *gasterosteus*, *labrus*, *crenilabrus*, *biennius*, *gobius*, and *cottus*. The algae, which serve at once as ornaments and shelter for the animals, and as purifiers of the water, appear to bear their new situation as well as the lively zoophytes, and no difficulty has presented itself, so far, to the conservation of both. The collection is altogether from the British seas, but the building is so constructed as to be capable of being enlarged, and the Society does not despair of exhibiting some of the more striking tropical and intertropical forms of invertebrate animals. The most complete portion of the collection are the *Actinias*, among which the specimens of *A. dianthus*, *parasitica*, *crassicornis*, are truly magnificent. The rare *Adamia palliata*, *Actinea nivea*,

and *A. miniata*, are also objects which merit more than passing attention. The shelled molluscs are at present indicated rather than represented; but the vivacity displayed by the *pectens* and *littorine* are a sufficient guarantee for what may be done with them hereafter. The star-fish appear to be rather more difficult in treatment, but among those displayed in the tank appropriated to them are two fine specimens of *palmipes membranaceus*. *Echini* are not unfrequent, and gorgeously coloured *ophiocomas* and *solasters* brighten up the dark stones and shaded recesses of the *algæ* with an effulgence which is irresistibly charming. A few *holothurians* complete the series of this division of the British *radiata*, which the work of Professor Edward Forbes has rendered more popularly known than any other. The *crustacea*, too, which occupy the adjoining tank, are as numerous in species as they are lively in action. The tanks, visible on both sides, afford 390 square feet of view, and contain seven tons of sea-water. Of the marine fish, of which the blennies and *cotti* are almost always at the bottom, it may be said that their habits are being now, for the first time, investigated with success. This exhibition of living fish and invertebrates, besides exciting much curiosity, will be of most impressive usefulness to the student, to whom they have been only known hitherto by books and dried remains.

KING'S COLLEGE HOSPITAL. The Governors have every reasonable expectation that the new wing now being erected will be ready for the reception of inmates next February. The other wing, which will cost £18,254, cannot be commenced until the whole or greater part of the amount is subscribed.

SINGULAR BEQUEST. Earl Beauchamp bequeathed £60,000 for the building of almshouses at Newland, Worcestershire, on condition that within twelve months some person gives a site for their erection. That failing, the legacy goes to St. George's Hospital, London.

ROYAL COLLEGE OF SURGEONS. The following circular has been sent to the Fellows:—"Royal College of Surgeons of England, June 1, 1853.—**SIR**,—I am directed to acquaint you that a meeting of the Fellows of this College will be held at the Hall of the College, in Lincoln's-inn-fields, on Thursday, the 7th day of July next, at one o'clock in the afternoon precisely, for the election of three Fellows into the Council of the College, in the room of three members going out in rotation. I enclose, for your information, extracts from the charter and bye-laws relating to the election of members of council.—I am, **SIR**, your most obedient servant, EDMUND BELFOUR, Secretary." The retiring members of the council are Mr. Luke, of the London Hospital, and Messrs. Wormald and Skey, of St. Bartholomew's Hospital. These gentlemen, with Mr. John Hilton, of Guy's Hospital, offer themselves for the seats in the Council.—The Fellows' Dinner will take place at the Freemasons' Tavern, in the evening of the same day, and will be presided over by Mr. Wilson, the Senior Surgeon of the Royal Infirmary, Manchester. Mr. William Adams is the honorary secretary.

JOSEPH FRANCIS OLLIFFE, M.D., Physician to Her Majesty's Embassy at Paris, was presented by Viscount Palmerston, at the late Court and Privy Council, and had the honour of Knighthood conferred upon him by the Queen.

THE CRIMINAL ABORTION CASE, which we made the subject of remark (May 13, p. 410), has been postponed till next session, when the prisoners Cunningham, Currie, and Thomas, will be tried for "the felonious use of certain instruments with the intent to produce abortion".

ROYAL COLLEGE OF SURGEONS:—PASS LIST. MEMBERS admitted at the meeting of the Court of Examiners on the 6th June:—Joshua Edward Adkins, East Stonehouse, Devon; James Beatty, Oldbury, Worcestershire; Charles Hooper, Buntingford, Herts; Philip Giffard Martel, Guernsey; John Natten Radcliffe, Leeds; Alfred Whittle, Liverpool.

June 10th:—Henry William Alexander Coleman, Elstree, Herts; Robert Death, New Broad Street; Henry Jones, Soho Square; Bransby Roberts, North Building, Finsbury Circus; John Charles Robertson, Waterloo, Portsmouth; Edward Sidebottom, Mottram, Cheshire; Donald Patrick Stewart, Blair Athol, Perthshire; and Henry Webster, Dulwich.

LICENTIATES IN MIDWIFERY admitted at the meeting of the Board of Examiners on the 8th instant:—John Hutchinson Baylis, Lower Kennington Lane, diploma of membership dated May 20th, 1830; John Maule Sutton, Greenwich, January 1st, 1851; Major Greenwood, St. Pancras, December 10th, 1852; George Henry Hope, Seaforth, near Liverpool, May 27th, 1853; William Leshley, Gloucester Street, Portman Square, July 31st,

1843; Maurice Griffith Evans, Blaenafu, April 8th, 1853; Robert Dempster, Brighton, April 8th, 1853; Samuel Cardozo, Redruth, May 27th, 1853; Robert Charles Croft, Wimbledon, May 30th, 1853; Nicholas Hardcastle, Newcastle-on-Tyne, June 3rd, 1853.

APOTHECARIES' HALL:—PASS LIST. Thursday, June 9th, 1853:—William Dale, Kirby-moorside, Yorkshire; Andrew Harvey; William Hewitt, Liverpool; James Fielden Howard, Shaw, Lancashire; William Randall Mackley, Bradford, Yorkshire; John Charles Robertson, Waterloo Villa, Portsmouth; James Rhodes, Glossop; and Edward Hemmings Snaod, Ashford, Kent.

APPOINTMENTS.

[* An asterisk is prefixed to the names of Members of the Association.]

CARTER, H. V., Esq., of St. George's Hospital, was appointed Student in Human and Comparative Anatomy of the Royal College of Surgeons, at a meeting of the Council, on Wednesday, June 15th, 1853.

OBITUARY.

[* An asterisk is prefixed to the names of those who at the time of their decease were Members of the Association.]

BAILEY, J. Gordon, M.D., Lecturer on Midwifery in the Hunterian School of Medicine, at Penton Street, Pentonville, from suicide by prussic acid, aged 29, on June 8.

BRIEN, Robert, M.D., at 26, St. Mary's Road, Islington, aged 65, on June 8.

COWARD, William B., Esq., Surgeon, at his residence, near Tiverton, Devon, on June 3.

GIBSON, John, Esq., Surgeon, at Dalston, of consumption, aged 28, on June 18.

GOODGER, William Frederick, Esq., Surgeon, at Ladbroke Place, Notting Hill, on May 29.

GRIFFITH, Samuel M., Esq., Surgeon H.E.I.C.S., at Madras, aged 52, on November 5, 1852.

LAWSON, William Syme, M.D., H.E.I.C.S., at Burmah, of Cholera, on March 29.

LINDOE, R. F., M.D., Physician to the Bath General Hospital, at Stratford, near Salisbury, on June 7.

MACLISE, Alexander, Esq., of 14, Russell Place, Fitzroy Square, at Kingstown, near Dublin, aged 75, on June 8.

McKECHNIE, Robert, M.D., at Smith-hills, Paisley, Renfrewshire, on June 9.

STEAD, Henry C. M., Esq., Surgeon, at Harrogate, Yorkshire, aged 34, on June 13.

WESTCOTT, Charles Stephen, Esq., Surgeon, late of Ringwood, at Ensbury, near Longham, Dorset, on May 28.

* **WING, Richard, Esq.**, Surgeon, at Burrough-on-the-Hill, Leicestershire, on June 16.

BOOKS RECEIVED.

TO CORRESPONDENTS.

MUTUA MISERICORDIA. If the writer of a letter bearing this signature, addressed to A.B. Surditas, M.D., will send or write to our office, a communication will be forwarded to any address given.

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London: or to the Editor of the Journal. Letters requiring immediate attention, and revised proofs ought invariably to be sent to Putney.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XXVI.

LONDON: FRIDAY EVENING, JULY 1, 1853.

NEW SERIES.

GENTLEMEN WISHING TO JOIN THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION ARE REQUESTED TO APPLY TO THE GENERAL SECRETARY, TO THE BRANCH SECRETARIES, OR TO THE EDITOR OF THE JOURNAL. The Annual Subscription is One Guinea. Members receive the Journal free by post.

The ANNUAL MEETING will be held at Swansea on the 10th and 11th of August. Gentlemen who have communications to read to the Meeting are requested to give notice of their intention to the Secretary. Communications will be called for in the order in which the Secretary has received notice from the respective authors. Vide p. 470 of May 27 for various details.

We must remind correspondents that, although they may wish their letters to appear under special signatures, it is absolutely necessary to communicate in confidence their names and addresses to the Editor.

SUNDAY SIGHTS AND SUNDAY SLAVERY.

It is always unpleasant to discover that we differ from those whom we esteem, especially when the subject about which the diversity of opinion exists is mutually regarded as one of the highest importance. It is, therefore, with sorrow that we find that the sentiments, which we expressed last week upon the Sunday question, are in opposition to views set forth in a subsequent page of this day's JOURNAL, by one whose writings and actions—public as well as private—have earned for him the respect of the profession, and have closely associated him in the minds of all who know him, with the united charms of a clear intellect and a genial heart. We regret, then, exceedingly that Dr. Forbes should stand forth in strong antagonism to the six hundred and forty physicians, surgeons, and general practitioners, who have subscribed a petition to Parliament against such an alteration of the statute law of England, as would enable the proprietors of the new Crystal Palace at Sydenham to open it for gain on Sundays. Nevertheless, we do not feel that we can abate one word which we formerly advanced in approval of the general objects of the petitioners. To us belongs not only the liberty, but the high and responsible duty of commenting, from week to week, upon the professional topics of the day, before a large and enlightened society of medical practitioners, among whom must necessarily exist considerable diversities of opinion upon many of the subjects which claim our attention. We, therefore, feel that in discussing this and every other question which arises, the right course to pursue is—without wearying and wasting ourselves in a vain attempt to discover and conform to a creed which we fancy to be of universal acceptability—to throw ourselves upon the generosity of our constituents, and give utterance to our own sentiments with the same unshackled candour which is rightfully exercised by Dr. Forbes, and by other associates who hold and wish to propagate opinions contrary to those advocated in the editorial articles. In this way only can the problem be solved of any large combination of educated and thinking men, maintaining a fair press, and a free editor. The con-

viction that the ASSOCIATION is zealously determined to maintain both in conjunction is our constant support, and our presiding star of duty. This conviction it is which now emboldens us to urge, as a practical objection to the doctrines of Dr. Forbes, that Sunday sights necessitate Sunday slavery.

Upon physical, moral, and religious grounds, Dr. Forbes demands abundant opportunities of extradomestic Sunday recreation for the public. He claims, as a boon to the working-classes, the existence of means for "relaxation in the open air of the country, whether carried thither by omnibus, boat, or rail". As we said last week, we are not the advocates of puritanical Sunday observance: and so far from having any objection "to relaxation in the open air", we believe that, while it imparts health to the body, it is also one of the best means of preparing the mind for such special duties of the day as religious service, domestic fellowship, and self-examination. With the poet we would wish to say—

"Hail, Sabbath! thee I hail, the poor man's day.
The pale mechanic now has leave to breathe
The morning air, pure from the city's smoke;
While, wandering slowly up the river side,
He meditates on Him, whose power he marks
In each green tree that proudly spreads the bough,
As in the tiny dew-bent flowers that bloom
Around its roots; and while he thus surveys,
With elevated joy each rural charm,
He hopes, yet fears presumption in the hope,
That heaven may be one Sabbath without end."

In recommending, however, to the poor man, "relaxation in the open air" on Sunday, we would not advise him to take it in company with a mob of excursionists, and to complete the pleasures of the day, according to the programme of Sir James Graham, by seeking comforts in the public-house which he cannot command at home.

"On other days the man of toil is doomed
To eat his joyless bread, lonely;"

and on the only day on which he can become acquainted with his children, take counsel together with the partner of his life, and consider his own destiny as an immortal being, we feel assured that it is better for him by far, that he should be—

"Embosom'd in his home,
And share the frugal meal with those he loves."

But, after all, it is not by the "men of toil" that the Crystal Palace would be chiefly frequented on Sunday, if we may draw a conclusion from the fact that it is not by them that the omnibus, boat, and rail, are most patronized on that day. It is well known that those, who chiefly fill the coffers of the speculators in cheap Sunday trips by land and water, belong to the middle class of society, with a sprinkling of the richer artisans. To increase public amusements on Sunday is, so far as the poor and the toil-worn are concerned, to increase Sunday labour. The blockades of omnibuses, cabs, and country vans, which we were in the habit of witnessing in Piccadilly, Knightsbridge, and

Kensington, during the Great Exhibition of 1851, would be repeated every Sunday from Temple Bar to London Bridge, were the proprietors of the new Crystal Palace to obtain the alteration of the law which they desire. Thousands of men, already severely worked during six days of the week, would be forced to perform extra service on the seventh; and thus Sunday labour, already a gigantic incubus upon the needy, would be increased, and we should have at once a palpable extension of that slavery, worse than Egyptian bondage, which grasping capitalists are enabled, through the selfishness of the majority, to impose upon the minority. Sunday slavery, upon a large scale, is an inseparable companion of Sunday sights. This is a fact which admits of endless illustration and of the amplest corroboration. We are prepared to prove that "pleasuring" and unnecessary travelling on Sunday doom a large percentage of the adult community to cheerless slavery, from Sunday morning to Saturday night. And if it be so, can any words be too hard, whereby to designate this cruel tyranny of the many over the few? Is this "the noble philanthropy and that tender humanity which form the very essence of our profession"? No! it is treating man less tenderly than it is lawful to treat the beasts that perish. And if there be an eternity, for which the short span of time is the season of preparation, surely the addition of Sunday slavery to the ceaseless toil of the other six days is not a small crime. If man really be born to immortality, the establishment of so strict a quarantine between the creature and the Creator is a crime of magnitude too enormous for words to compass.

The manner in which each individual observes Sunday is a matter between himself and his own conscience; but when greedy capitalists combine with one section of the public to exact Sunday labour in addition to ceaseless work-day toil from another section, albeit a minority, the question emerges from its mere individuality, and assumes a national character. In this latter light we have chiefly considered it, both now and formerly; but we trust that, while we have advocated the recognition of a weekly Sabbath chiefly as a fundamental principle in sound social economics, we have not done it in so exclusive a way as to cloud the perception of that direct personal interest, which every one has in the right understanding and practical application of the question.

We have disclaimed the Sunday rituals of the Puritans and of the Parisians; but we do not place them on the same level of error. We are satisfied that the evils incidental to the one system are inconsiderable, in comparison with the evils inseparably connected with the other.

On this point, our views do not materially differ from those so well expressed in the following reflections upon "Sundays", transcribed from that delightful little volume, *Evening Thoughts by a Physician*. The passage is peculiarly applicable to the whole question now before us.

"SUNDAYS. How is it that many popular writers, who sympathise with the poorer classes, who seem to have their good at heart, and consider that good to depend very much on intellectual progress, wish to undermine the strict and even Judaical observance of Sunday? What framer of a Utopia could dream of more, than, in a state of things requiring the hard toil of the many as a condition of existence, yet still a devotion of one whole day in seven to the sole culture of mental philosophy, from a text-book which contains the purest and loftiest principles of ethics, set forth imaginatively, metaphysically, practically, affectionately—in poetry, maxims, philosophical reasoning—illus-

trated in parables, anecdotes, biographies—in the history of the oldest nation—and, finally, in the example of a pure and perfect life? and besides all this, that the Word itself, rightly used under certain conditions which all may fulfil, should be the means of giving the power of acting up to this knowledge, and thus producing a nation of working-men with pure, unselfish, unsensual hearts and refined minds, bent on approaching a glorious ideal standard? For this is the Idea of the Sunday by which it should be judged.

"There is another argument, which is, to my own mind, very conclusive. Have I, or has any one, when looking back at life, ever regretted that any number of Sundays had been kept even with puritanical strictness? Though such observance was attended by self-denial, and even by the irksome restraint of others, was it not, when viewed soberly from a distance, just like all self-denial and discipline, acknowledged by the self-examiner to have been of more use to the character, than if the day had been one of amusement? 'To scorn delight and live laborious days', is the very characteristic of the *man* we respect; and yet we would train a nation of *men* by another rule, expecting to rear masculine intellects on the soft diet of a disguised Epicureanism." (pp. 84-86.)

Should we have occasion to return to the subjects mooted in the communications of Dr. Stewart and Dr. Forbes, we shall present the sanitary and medical aspects of the Sunday question, to which, as yet, we have not adverted. In the meantime, we aver that it can be proved from medical statistics, and from physiology, that the ordinance of a stated weekly *day of rest at home* is a signal token of Divine Benevolence to all men, but especially to the poor.

"Yes, child of suffering, thou may'st well be sure
He who ordained the Sabbath loves the poor."

THE SYDENHAM SOCIETY AND ITS EXECUTIVE.

AN advertisement in our last number has recalled our attention to the Sydenham Society. Apart from the claims which such a society may be supposed to have on our attention as journalists, we frequently receive communications having reference to its proceedings and management. Though we have not hitherto been able specifically to reply to our correspondents, we have not been unmindful of their letters, but we have taken pains to inform ourselves on the various points to which they have directed our attention.

The very existence, in this country, of a society founded to promote the study of sound medical literature is a highly gratifying fact; whilst the support which it has received, and the age which it has attained, constitute good *prima facie* evidence that it is largely accomplishing the objects for which it was instituted. At the same time, we can quite understand that many members may have been disappointed by not finding their individual expectations answered. But no one, we think, can glance at the row of handsome volumes on his shelf, or peruse the list which appeared in our last number, without acknowledging that the original intentions of the Society have been well and truly fulfilled. We would not be supposed to justify, in every instance, the selections made. But, looking to the varied requirements of so large a body of subscribers, and the differences of opinion that must exist among those to whom the selection of works is deputed, we must honestly confess that the duties of the council have, in this respect, been performed in a way creditable to their judgment and literary character. The duties of a member of the council of the Sydenham Society are far from being nominal; and we do not think that suffi-

cient gratitude has been evinced by the profession, for the time and labour generously and disinterestedly afforded by the many distinguished men, who originated and have conducted the affairs of this society.

The distribution of patronage, always a very delicate matter, rarely fails to elicit charges of jobbing and favoritism, however conscientious and careful the patrons may be. It was not, therefore, to be expected that the managers of the Sydenham Society should escape scatheless of such insinuations; but these insinuations were groundless. In more than one instance, we know that the Council have experienced considerable difficulty in obtaining the services of competent editors; but we have never heard it so much as hinted that, in any case, exception could be taken to the fitness of those that have been entrusted with editorial duties.

After all, the main question is, How far does the Society merit the support of the profession? Does it elevate the literary character of its members, encourage a taste for sound literature, and diffuse valuable works? If so, it is deserving of all encouragement. British medical literature boasts of some very distinguished names; and the writings of Sydenham, Harvey, and Hewson, are of world-wide reputation. But we much doubt whether this reputation has been more than traditional with the large mass of our profession. Yet, it would be difficult to point out any works better calculated to train and improve the minds of medical men. We think, therefore, that a great boon has been conferred on the profession by the new editions of these works, which have appeared and have been distributed under the auspices of the Sydenham Society.

The works of Paulus Ægineta and of Hippocrates, edited by Dr. Adams, constitute important additions to our medical literature. The very valuable work of Rokitsansky, in all probability, would never have been available to the majority of professional students, but for the Sydenham Society. Nor is the list wanting in works of a direct practical character.

We trust that for many years to come this Society will continue to enrich our literature, and elevate the character of our profession by the issue of works of lasting value. We shall be glad if any of our readers, whose attention has not hitherto been called to this Society, should by these remarks be induced to join its ranks.

ORIGINAL COMMUNICATIONS.

ON THE ACTIVE PROPERTIES OF HEMLOCK.

By CHARLES COGSWELL, M.D.

THE perusal of Dr. Osborne's paper *On the State Poison of the Athenians, used in the case of Socrates*, of which a copious abstract is given in the ASSOCIATION JOURNAL of the 10th of June, has reminded me of a passage in Valerius Maximus, which, so far as I am aware, has not yet been introduced into the discussion; although, in my estimation, it affords a more complete vindication of the truth of the account of the symptoms given by Plato, than any other I have seen quoted from the ancient writings. The subject is not merely one of historical interest, but particularly addresses itself to the attention of the members of the medical profession, who are practically concerned to know the real properties of a powerful drug which is recognised by the Pharmacopœias, and which occurs not unfrequently in their prescriptions; otherwise, there might be reason to apologize for so soon again bringing it prominently forward.

The practice of keeping a state poison, as is well known, was not confined to the Athenians. The Roman author whom I have mentioned speaks of it as existing among the Massilienses (the ancient people of Marseilles) and in the island of Ceos. The Massilienses were a colony of Ionians, who fled to Gaul to avoid the tyranny of the Persians; so that in all probability the institution had been borrowed from their countrymen in Asia Minor. According to Valerius Maximus, they had a poison prepared from hemlock (*venenum cicuta temperatum*) which was presented to any one who could

show sufficient reasons before the council of Six Hundred for wishing to die.

"This custom of the Massilienses" (he continues), "I conceive not to have had its origin in Gaul, but to have been imported from Greece, having met with it in the island of Ceos, at the time of my visit to Iulis, in company with Sextus Pompeius. For it then happened that a lady of the highest rank, but far advanced in years, having explained to the citizens her wish to terminate her existence, thought the event would be rendered more illustrious by being honoured with the presence of Pompey. And he, so highly distinguished, not less for his humanity than for the possession of every other virtue, was unable to refuse her entreaties. He went to see her, and endeavoured, by arguments which flowed from his lips in the richest stream of eloquence, to divert her from her design, but without success. Reclining on her couch, which seemed to have been arranged with more than usual care, the lady, now past ninety years of age, and graced with the utmost purity both of mind and person, raised herself on her elbow and thus addressed him: 'To thee, O Sextus Pompeius, may the gods render thanks; not the gods I am seeking, but those I am leaving; because thou hast neither disdained to desire me to live, nor to be the spectator of my death. But having always seen the face of future decked in smiles, I cannot bear to incur the risk of witnessing her frowns by prolonging my existence; I therefore exchange the short remainder of my days for a happy end, leaving on earth two daughters and a flock of seven grandchildren.' Then, after exhorting her relatives to dwell in harmony together, and distributing her patrimony among them, assigning the domestic instruments of sacrifice to her eldest daughter, she seized the cup in which the poison had been prepared (in quo venenum temperatum erat) with a steady right hand. Pouring out a libation to Mercury, and invoking his offices to conduct her to the happier abode in the infernal regions, she eagerly drank the fatal potion. And signifying in words what parts of her body were successively (subinde) being seized with rigor; when it was now approaching the viscera and the heart, she requested her daughter to perform the last duty of closing her eyes. Our eyes, on the contrary, though confounded at the unwonted spectacle, were sent away suffused in tears." (*Ex. Mem.*, lib. II, cap. VI.)

Here we are clearly given to understand that the writer was an actual eye-witness of the scene which he describes. Being a soldier, and not a physician, he is not very particular in giving the medical details; but we are able to gather with a sufficient degree of confidence from the narrative, that the leading symptom was paralysis, commencing at the lower extremities, and gradually encroaching on the trunk until it reached the thoracic organs, which was the signal of death. At this stage, the parting injunction to close the eyes indicates that the lady still retained the possession of her mental faculties; while the fact of her expecting the eyes to remain open, denotes that this was an ordinary sequel of death from the poison. There are obvious grounds also for the inference that catharsis was not anticipated. On the whole, the case, so far as we are furnished with the particulars, bears a strong resemblance to that of the Athenian philosopher; and not only this, but the absence of any note of surprise on the part of the narrator, supports the presumption that the symptoms were of a kind with which the public in those days were familiarly acquainted. Still, unfortunately, the real nature of the poison, that is, whether it consisted of hemlock alone or was compounded with some other ingredient, such as opium, is left in doubt by the peculiar form of the expression "*venenum cicuta temperatum*".

Allian informs us that the old men of Ceos, who could not feel satisfied in their consciences that they were able to be of any further use to the state, were required to present themselves at a festive board, or at some solemn sacrifice, crowned with garlands, and drink a cup of *akveior*. One of his commentators, referring elsewhere to the *akveior*, says it was so called because it grew in a place called Acone, near Heracles, in Pontus; and he directs us for his authority

to the third book of Athenæus. There is some confusion here, however, almost as a matter of course. Athenæus has been mentioning, *apropos* of antidotes, that Clearchus, the tyrant of Heraclea, was wont to amuse himself by putting his subjects to death. Some he would despatch by honest butchery, others by giving them *κένευον*; but as soon as the second mode of gratifying the royal taste was noised abroad, everybody took the precaution before leaving home to fortify himself with a dose of rue (*ῥήγανον*), in consequence of no evil effects resulted to those "*πυθόνας τὸν κένευον*" — to those who drank the *aconite*. (*Deipnos*, ed. 1857, p. 85.) It is evident that he uses the word *κένευον* in the general sense of a 'poison'.

Dr. Osborne endeavours to prove that Dr. Christison is wrong in considering the symptoms attributed to hemlock in the account of the death of Socrates, as irreconcilable with the effects of any poison now known. But that opinion was expressed in 1836, and must have been founded on the data which existed up to that time. It will be seen, on consulting a later publication, that for some years past he has adopted the same view as that now so ably maintained in the *Dublin Journal*; and this change of opinion appears to have taken place subsequently to the occurrence, in 1845, of Dr. Hughes Bennett's remarkable case of poisoning with the fresh leaves of the *Conium maculatum*, in which the symptoms bore a near resemblance to those said to have been produced by the ancient *κένευον* or *cicuta*. Thus, in the edition of the *Edinburgh Dispensatory*, published in 1842, Dr. Christison observes, under the head of *Conium*, "the accounts given by Nicander and Plato of its action as a poison, do not tally well with what is now known of its effects;" but in the next edition, or that of 1848, he says, "the action of this plant as a poison corresponds closely with the description given by Nicander and Plato of the *κένευον*, or state poison of the Greeks." We may, therefore, now consider so much of the difficulty connected with the properties of hemlock as finally disposed of, seeing that two such authorities have arrived at the same conviction as to the identity of the ancient and modern poison, independently of one another.

Since the reintroduction of hemlock into practice in the last century by Baron Störck, a variety of accidental circumstances have conspired to create perplexity with regard to its physiological and medicinal properties; such as the uncertain identification of the plant in some of the recorded cases of poisoning; the changes in the composition of the juice wrought by difference of season; the discordant and often faulty processes employed in making its official preparations; and the fact of the strength of the extract being impaired more or less rapidly by age and exposure to the air. The encomiums bestowed upon it by Störck have also been deemed too extravagant; and the consequence is, that according to the usual course of reaction, the remedy has fallen comparatively into, perhaps, unmerited neglect. Making a fair allowance, however, for the sources of discrepancy just mentioned, and supposing it probable that he was mistaken in his diagnosis when he states that hemlock is a cure for cancer, I am not sure that his results fail to harmonize substantially with those of more recent inquiries. He gives a formula for preparing the extract, very similar to those now directed by the College, as follows:—

R. *Herbæ recentis cicutæ* q. s.

"*Exprimatur succus, isque recens lentissimo igne in vase terreo (sæpius agitando ne amburatur) coquatur ad spissam extracti consistentiam; hoc extractum s. q. pulveris foliorum cicutæ in massam pilularum subigatur; ex qua fiant pilulæ granorum duorum.*" (*Libellus de cicuta. Editio altera, 1761.*)

His practice was to commence with one of the pills night and morning; on the third or fourth day he added another pill; on the eighth day he administered two pills thrice a day; and so he went on gradually increasing the quantity until it reached a drachm or a drachm and a half daily. All this time the case was carefully watched, and the remedy stopped in the event of any adverse indications making their appearance. Fomentations of the leaves were

also applied externally in suitable cases. In reply to his critics, he said he made no pretence of meeting with invariable success; he was satisfied, if, out of a hundred cases given over by other practitioners, he could succeed in relieving or curing one; but, nevertheless, his proportion of favourable results was much greater than this. (*Libellus secundus.*)

Owing to the conflicting statements of authors, doubts at present exist as to whether or not hemlock is possessed of deobstruent properties. Störck alleges, aphoristically, in two of his corollaries, that it has no such property; that it disturbs none of the functions, secretions, or excretions; that it acts insensibly, and neither excites purging nor vomiting; diuresis nor perspiration. In like manner, we are also told by Dr. Christison, that "the deobstruent virtues of hemlock are now almost universally discredited;" and "its diuretic virtues are too unimportant to be available in practice." The rule, therefore, seems to be that the extract of hemlock has no tendency to relax the bowels. And yet even the experience of Störck himself may be cited, to prove that the rule is not without an occasional exception. Thus, in the seventh case of his first monograph, which was that of a lady taking three of the pills night and morning, he mentions that the medicine induced daily two or three liquid evacuations beyond what was customary. Judging from my own opportunities of observation, I should feel inclined to adopt both the rule and the exception; for although in general there has been no action on the bowels, still, in a few instances, where they were usually regular, and even rather sensitive, the patients have found that the extract had a laxative effect upon them. Again, Dr. Osborne states in unqualified terms that the fresh juice is cathartic; so that the following is probably the correct conclusion to be drawn from the whole of the evidence. The natural juice of hemlock is cathartic; but during the progress of inspissation to form the extract, it undergoes some undefined change of composition which deprives it of any marked possession of that property, although, in some constitutions, it still retains the power of increasing the action of the bowels. Armed with the knowledge of this difference in the effects of the fresh juice, and the extract which Dr. Osborne himself admits, we may return to assail the still remaining objection to the perfect identity of the Greek poison with the *conium maculatum*; viz., that the former does not appear to be cathartic, by suggesting that it was probably preserved in the concentrated state, and diluted as occasion required. This not very unreasonable supposition removes the necessity of imagining that just so much opium was used as merely to confine the bowels; while it would argue a refinement of science as well as cruelty to have managed deliberately to adjust the amount of opium so as not to affect the brain, and leave a criminal conscious of the horrors of his situation under the characteristic influence of hemlock. But the question might be discussed hypothetically to any length, without being brought to a satisfactory conclusion; and can only be settled, if at all, by a further appeal to facts.

There is another highly interesting subject connected with the physiological action of hemlock, to which I shall now proceed. Dr. Christison has inferred, from his experiments with conia on some of the mammalia, that it exhausts the energy of the spinal cord and voluntary muscles, but leaves the heart's action unimpaired. He states, moreover, that when applied locally, it acts as an irritant; agreeably to which I have also found, as recorded elsewhere (*Lancet*, 1852), that it excites the contraction of the voluntary muscles and the bowels. In one of Dr. Christison's experiments, when two grains of conia, neutralised with thirty drops of weak hydrochloric acid, were injected into the femoral vein of a young dog, "the animal died before there was time to note the interval." But Mr. Blake, who opposes the doctrine of the sympathetic action of poisons, denies the accuracy of this observation, and insists that a sufficient time always elapses between the application of a poison and its effects, to allow of its completing the round of the circulation.

Some experiments which I performed in 1850, with Dr. Glover, may assist in clearing up this difficulty. Conia given to frogs by the mouth, or inserted beneath the skin of the leg, produced (besides speedy local paralysis in the latter instance) general flaccidity and prostration, terminating in the total abolition of consciousness in from twenty minutes to an hour. The heart, however, continued to beat for three or four hours afterwards. A little of the poison was next applied to the outer surface of the ventricle. Immediately the heart began to contract and extend itself longitudinally with more vigour than before; but, in the course of a minute, the ventricle grew paler, exhibited furrows and prominences on its surface, and beat very slowly. In other experiments, an aperture was made at the apex of the ventricle (an operation which does not much interfere with the heart's action in these animals), and a small quantity of conia was thrown into the cavity through a glass tube. The ventricle instantly contracted to its utmost limit, and refused any longer to receive the blood from the auricles, which continued to beat as before. Usually, it stopped altogether, but once it renewed its pulsations in a quarter of an hour, and continued them for several minutes. And it is worthy of particular mention, that the same phenomena occurred, whether the organ remained *in situ*, or was separated from its attachments, and laid on the table—a remark which also applies to the bowels, which contract under the stimulus of conia and other irritants, whether in or out of the body.

With these facts before us, I think there can be no difficulty in admitting the perfect accuracy of the above observation with respect to the rapidity of death in the dog—an animal to which an interruption of the heart's action would be immediately fatal. The poison acted neither directly nor indirectly through the medium of the nerves; but, in its character as a local stimulant, roused the independent irritability of the muscular structure of the heart, producing an abnormal state of contraction, and preventing it from carrying on the circulation. Such appears to be the true explanation of a fact which, with more of the like nature, has occasioned no slight perplexity to physiologists engaged in investigating the theory of the action of medicines. How far it is calculated to answer the purpose of the *experimentum crucis* which the author of the *Treatise on Poisons* considers necessary to decide between the doctrines of sympathy and absorption, this is not the proper place to inquire; but I may be permitted to observe, that, as their respective advocates derive their conclusions from a variety of unconnected sources, it is not easy to imagine any single experiment which is capable of meeting the whole of the arguments on either side.

Having begun with a quotation, I may appropriately finish with another: "Nil tamen quod temerarium foret audebo; sed omnia et in brutis et in me experiri, antequam ea homini aegrotanti præbuero."—(*Störck*.)

Barnard Street, Russell Square, June 1853.

PATHOLOGY AND TREATMENT OF CHRONIC INDURATION OF THE MAMMA.

By JOHN BIRKETT, F.R.C.S. Eng., and Assistant-Surgeon to Guy's Hospital.

[Read before the Harveian Society of London.]

THE morbid condition of the mammary gland, to which I am about to direct the attention of the Harveian Society this evening, has been almost entirely overlooked by writers upon the pathology of the breast. The nearest approach to anything of the kind is at the termination of a paper by M. J. A. Giraudeau, entitled "*Quelques Considérations sur l'Anatomie Chirurgicale de la Région Mammaire*". (*Mém. de la Soc. de Chir. de Paris*, tome ii., pp. 205 to 207). Professor Syme also gives a short notice of the disease in his "*Principles of Surgery*".

Anatomy of a Healthy Mamma. If the healthy mam-

mary gland of a woman, who has not recently suckled, be examined, it exhibits to the unassisted eye a remarkably opaque white homogenous surface where cut. With very attentive examination, and by allowing the light to fall upon a section at certain angles, the surface appears undulating, and minute irregularities are perceptible. To the touch, it is unyielding and tough; and, occasionally, small irregularities are recognizable. In such a gland, which may be regarded as the type of the normal condition of the organ when in a *passive* condition, the terminal cæci, the secreting portion of the gland, are with very great difficulty detected by microscopic investigation. The object, however prepared, exhibits nothing but a fibre tissue; the fibres being chiefly of the filamentous and double outlined varieties.

Still there is a peculiar aspect about the tissues which at once strikes a practised observer, and which offers a remarkable contrast with the ordinary uniting or areolar tissue of other parts. There appear to be spaces or lacunæ between the fibres, in which a few scattered epithelium cells may be here and there discovered. After the examination of a very large number of mammary glands, at all periods of life and at very different intervals during pregnancy and lactation, as well as after the cessation of this function, I have no hesitation in stating that this organ, when in a *perfectly quiescent and unexcited condition*, exhibits in the slightest degree that is possible the essentials of a secreting organ. The only permanent structures appear to be the excretory ducts. The secreting portion undergoes a remarkable state of atrophy.

Anatomy of a Diseased Mamma. Under morbid action, however, and probably as the result of that remarkable sympathy existing between the several portions of the generative organs and their functions, great changes take place.

It is to the consideration of these phenomena that the following observations will be devoted.

The subject may be divided into;

I. GENERAL INDURATION OF THE MAMMARY GLAND.

II. LOBULAR INDURATION.

The morbid condition of the tissues composing the gland is identical in both these varieties, the only difference being that in the first form *all* the lobes constituting the breast are affected, whilst, in the second, one, two, three or more lobes are alone involved in the morbid action.

A breast thus diseased, when cut, exhibits to the unassisted eye a pinkish tint, its texture is close, but it does not appear of the same homogenous surface throughout. The section is sometimes smooth, but, in many cases, it is almost granular. To the touch, it is hard, quite incompressible, and with difficulty torn. Very often minute vesicular bodies are dispersed throughout the gland, or even small cysts may be discovered in several parts of it. These contain a serous fluid in one instance; and in another, a little mucoid, greasy material.

When examined with the assistance of the microscope, the fibre-element of the organ does not exhibit any appreciable change. I mean to imply by "fibre-element" the areolar or uniting tissue. The secreting portion of the gland-tissue, on the contrary, offers most striking deviations from a healthy condition. The acini, which are remarkably distinct and rigid, clearly exhibit, when torn up, the cæcal terminations of the ducts, closely packed together and opaque. Dilute acetic acid, being added to the preparation, often renders the observation of the object more satisfactory. These cæcal terminations of the ducts are crowded with epithelial cells, and they appear to be filled almost, if we may so say, to bursting point. Such, then, may be the morbid state of the gland-tissue of the entire breast, or of one or more of its lobes. The abnormal condition seems to depend upon an excited action in the terminal cæci, inducing an excessive production of epithelium which does not escape by the ducts. I have never been able to satisfy myself, from ocular demonstration, of the existence of any disease in the areolar tissue, but I think that further observation may prove that there is.

i. When the entire gland is involved, two very distinct conditions are exhibited by the mamma, regarded, that is, *en masse*. In one case the gland is small, the entire organ is closely fixed against the chest, the nipple looks more like a wart and the areola glands are very distinct. When grasped between the fingers from side to side it feels like a disc of condensed, rigid tissue, and it can be drawn forwards from the chest and the fingers placed behind its borders.

In the other case, the breast is remarkably large and pendulous; attached to the thorax by a rather narrow neck, it is of a flask-like or pear shape. When supported on the hand it is extremely heavy; and, when grasped, the lobes are distinctly perceptible, and the entire mass is very hard. The nipple is usually large, dark, and prominent, unless congenitally defective. The areola is expanded, of a dark brown tint, and the glands therein are generally well developed.

ii. If lobular indurations exist, the affected breast is perhaps rather larger than the healthy one. In one, two, or more quarters of the breast, lumps or knots, or, as these indurations are often termed, "tumours", are easily felt, and, perhaps, even the entire organ is more firm than when in a healthy condition. But it is to the existence of one or more indurated lobes that I would especially direct attention, in order that this complaint may be duly recognized, and not mixed up, as it undoubtedly too often is, with real tumours of one kind or the other.

It should be carefully borne in mind that the disease which we are now describing is a morbid state of a part of the gland, not a new structure, or new growth, and consequently not a tumour in the modern and more correct acceptance of the term. It is, in truth, a disease of and not merely in the gland tissue. The importance of this consideration becomes at once apparent, when such cases as these come before us and demand surgical treatment.

Age at which Induration occurs. This morbid condition of the gland tissue occurs in females between twenty-five and forty years of age. It is much more frequently met with in single than in married women, and in the sterile, rather than in those who are prolific and have suckled their children.

General Health, and especially the Catamenia. The general health is in most cases disturbed, but the functions of the generative organs manifest the greatest amount of derangement. The catamenia appear irregularly, sometimes they are scanty, in other cases too abundant. A total cessation of the menstrual discharge occasionally exists, and, if it should show itself, it is attended with intense pain and great constitutional disturbance. I have seen this disease in the right breast and not in the left, during the early months of pregnancy. The case occurred in a woman who married about thirty, and who, before this, had been always subject to considerable derangement of the catamenia, and sympathetic constitutional disturbance.

External appearance of the Breast. The local signs, as manifested by the aspect of the organ, are not very prominently marked. There is usually a somewhat tense, full appearance of the skin, with a rather conical outline in the region of the nipple and areola, when the whole organ is affected; and if one or more lobes only are diseased, slight irregularities or elevations may indicate their site. There is never any inflammatory redness present.

Manipular Indications. The chief manifestation from touch is extreme firmness of the substance of the breast, rather than hardness, together with its disc-like figure beneath the skin, to which it feels loosely attached, and the capability that exists of drawing it forwards *en masse* from its posterior connexions. Single lobes feel remarkably hard, which perhaps arises from a comparison of the softer parts of the breast; and, doubtless, by the sense of touch alone, they are scarcely distinguishable from genuine "tumours". But the remarkable and characteristic isolation observable in most cases of glandular mammary tumours is absent, for the induration in the cases under consideration blends with the surrounding gland tissue. From circles of carcinoma, the induration differs in being for

ever confined to the tissue of the gland itself; never, should the lump increase, does it involve or become adherent to the skin, nor does it influence the form and outline of the nipple during any period of its existence.

One or both Breasts affected. Both the mammae are sometimes affected with general or lobular induration, and at the same time. In the majority of cases, however, it is much more common to find that one alone has the priority; or that, as the one first affected resumes its normal state, the other assumes a morbid condition.

Sensations of the Patient. Women, the subject of this disease, are often compelled to endure great local suffering; and from this cause it has been no doubt generally regarded as a variety of the neuralgic affections of the breast. In some particulars, doubtless, these affections are closely allied; but as, in a practical point of view, the recognition of these indurations is so highly important, I do not consider that mere pain alone is sufficient to characterise the complaint. The pain is very often most intense; in some instances constant, in others intermittent; and it is usually most severe before the catamenial period. Pressure with the point of the finger over the intercostal foramina, through which issue the anterior cutaneous filaments of the intercostal nerves, causes great pain; and in lobular induration this is a very important point in establishing a correct diagnosis. The pain is not always confined to the mamma, but extends along the skin to the back, and along the inside of the arm.

Diagnosis. The facts before stated are sufficiently marked and peculiar to enable the surgeon to distinguish between this disease of the glandular tissue, and those tumours with which it is most likely to be confused; such as, for example, the "mammary glandular", the so-called "fibrous tumours", or "fibro-plastic", and "scirrhous". The first are not generally very painful, and if they should be, they are, at the same time, remarkably moveable and but loosely attached to the breast. The second but rarely occur in the mamma, and in the cases which I have seen they were painless. The last, in its early stage, is singularly free from pain, so much so, indeed, that this peculiarity is one of its most distinguishing features.

Prognosis. With sufficient evidence to determine that the disease under consideration is of no greater importance than would attach to induration of the gland tissue, a favourable prognosis may be unhesitatingly pronounced.

Treatment. This disease is amenable to local, combined with general constitutional treatment; and this circumstance has, doubtless, afforded opportunities to boast of the successful removal or dispersion of tumours, termed "scirrhous", by local applications, the first of which is pressure. M. Récamier (*Recherches sur le Traitement du Cancer, par la Compression Méthodique, simple ou combinée*, 2 vols., 8vo. Paris, 1829), in a work of considerable size, is perhaps the warmest advocate for this mode of treating cancerous tumours; but it is very remarkable that almost the only cases stated to have been cured, bear internal evidence in the detail of having belonged to the class of diseases to which this section is devoted. Who, for example, in the present day, will believe that a tumour—or, to quote the very words of the author, "un engorgement jugé cancéreux par M. le prof. Dubois" (*op. cit. t. i, Intro. p. xvi*)—was cured by the application of methodical compression in twelve days? or, that the first case (*op. cit. t. i, p. 19*) related, was one of cancer, as well as the fifteenth and sixteenth? They were undoubtedly all cases of chronic induration, and as such were curable. M. Maisonneuve also (*Leçons Cliniques sur les Affections Cancéreuses*. Paris, 1852; pp. 27, 28), speaking of "tumeurs fibro-plastiques", writes "nous ne savons aucun moyen de reconnaître d'une manière précise la nature des tumeurs fibro-plastiques avant leur extirpation"; yet, on the next page, we find, "c'est ainsi que, sans l'influence de saignées locales ou générales fréquemment répétées, par l'emploi méthodique d'une compression régulière, nous avons vu disparaître quelquefois des tumeurs de cette nature développées dans la région mammaire."

The treatment here described, namely, leeches locally and frequently applied, and methodical compression, are of eminent service in restoring to a healthy condition the mammary gland-tissue when in a state of induration; and I must here confess, that after repeated and long continued trials, I have never yet succeeded in producing absorption of any tumour which exhibited to me unequivocal indications of being a new growth.

The constitutional treatment consists in the administration of such medicines as improve the general health, and by this means restore the generative organs to a healthy performance of their functions. Aperients, tonics, wholesome food, change of air, and bodily exercise, perhaps the use of the shower-bath, or sea-bathing, and the withdrawal from all circumstances tending to excitement of the nervous system, will be found of service. Liquor potassæ given internally is, sometimes, also useful.

The local treatment must be regulated by the condition of the individual. Occasionally, a few leeches afford almost immediate, although temporary, relief from the pain. The application of the extract of belladonna and soap-cerate in equal parts spread upon lint, and supporting the gland with strips of plaister and a bandage, is also very useful. I have likewise known the placing a piece of thin gutta percha over the induration to lead to its absorption, as well as the application of the ceratum hydrargyri compositum spread upon lint. In some cases, the pain and sufferings are so intense, and they resist so obstinately all attempts to assuage them, that the patient is induced to submit to the removal of the breast. The operation has been performed under my observation in three or four instances, and success attended it.

I propose in a future communication to illustrate the preceding remarks by the detail of some cases.

Wellington Street, Southwark, June 1853.

CASES IN PRIVATE MIDWIFERY PRACTICE; WITH REMARKS.

By EDWARD L. FALLOON, Esq.

REPORTS of private midwifery practice are rarely submitted to the public. I have been induced to present the following tabular statement, after perusing an interesting paper on this subject from the pen of Dr. G. Hamilton, of Falkirk, in the *ASSOCIATION JOURNAL* for May 27th, p. 467. Up to this time, our statistical results have mainly rested on hospital experience; but, in order to establish a just comparison between public and private midwifery practice, authentic reports of the latter require to be greatly increased.

The following 310 cases are reported exactly as they occurred in uninterrupted succession. I regret to say that I have only been in the habit of keeping notes of my midwifery cases during the last few years, although previously, during dispensary practice in Ireland, as also during some voyages to Australia, in charge of large numbers of emigrants, under the auspices of the Colonial Land and Emigration Commissioners, I had much experience in this department, often under most trying circumstances. The only record that remains—and it is thankfully impressed upon my mind—is this, that I never yet have had a single death in my midwifery practice.

In the published details of hospital and private midwifery practice, I am sorry to find that the old proverb of "doctors differing" comes true. Take the use of the forceps, for instance. Dr. Hamilton, of Falkirk, used them 41 times in 300 cases, occurring, too, "among a generally robust and healthy population", or less than 1 in 7; according to my table, 1 in 53; in Mr. Crosse's practice (of Norwich), 1 in 16; Dr. Merriman, 1 in 98; Dr. J. Clarke, 1 in 295; Ramsbotham, 1 in 729; Collins, 1 in 684: so that Dr. Hamilton enjoys an unenviable notoriety in this respect. Notwithstanding, his mortality-table is not high,

being 1 in 20 among mothers delivered by the forceps, while the children thus delivered were all living. Still, so far as my own experience goes, I think such frequent use of the forceps cannot be defended; nor, on the other hand, can I understand how some men pass a life-time in midwifery practice without ever using them at all. The last case of this kind I had was a woman aged 42. It was her first confinement. The mother and the child are living, and in health.

There are notes in my case-book, appended to some of the cases, which, though conveying nothing novel to men of my own standing, are yet eminently practical to the generation of surgeons arising around us. Medical men in general practice, like myself, are seldom able or inclined to write for publication; and perhaps they do not sufficiently estimate the value of their every-day experience to young beginners. A tersely told practical fact, read in a weekly journal, makes, I am convinced, far more impression than if it had been perused in an elementary work.

CASE I. INCISION OF RIGID OS UTERI. A primipara, aged 33. This was a most tedious labour, occasioned by uterine rigidity, which defied all efforts to overcome it. I remained with the patient for two days and two nights, and administered chloroform freely during most of the time. I resorted to venesection, injections, fomentations, manual dilatation, and nauseating remedies, without obtaining any progress, although the pains were strong throughout this treatment. It occurred to me that, as a breach of continuity was inevitable, it would make very little difference whether it was produced by the natural efforts or by mechanical means. Acting on this view of the case, and without any authority, I took a probe-pointed bistoury, and made it like a hernia knife; and with this I incised the uterus. In an hour, all was safely over.

I was not aware till lately that the practice which I adopted has been recommended by high authority. Two cases are reported, and the practice discussed, by Mr. Houghton, in the *Dublin Quarterly Journal*. Among its advocates are to be found the eminent names of Murphy, Lever, T. Smith, and E. Kennedy. I have since attended the same woman, when her labour was as remarkable for its rapidity as the former was for its tediousness. In a similar difficulty, I should have no hesitation in adopting a similar course.

CASE II. TWINS: NINTH PREGNANCY. The placenta was detached at the commencement of labour. Copious flooding occurred whilst the uterus was dilating. I ruptured the membranes, when the head of the first child descended with the face towards the pubis; it was born dead, and with great difficulty. The membranes of the second descended soon afterwards, in consequence of a dose of ergot previously administered, in anticipation of flooding. Both hands presented. I succeeded in replacing one hand, and bringing the head over the brim of the pelvis (as the uterus was acting too violently to turn). It descended with one arm, face presenting; and, as the fœtus was dead, I evacuated the cranium, and brought it down with the crotchet, without much force. The placenta of the last followed immediately, and the other came away soon after, without inordinate flooding. This woman is again pregnant.

CASE III. TWINS: PLACENTA PRÆVIA: TWELFTH PREGNANCY. This case was somewhat similar to the above; but the practice was different. My notes only state, that the placenta presented, that I turned both children, and that there was hæmorrhage, both before and after delivery, to an alarming extent. This woman is again pregnant.

CASE IV. INTERNAL HÆMORRHAGE. This case answers in all respects to that published by Mr. George King, of Bath, in the *ASSOCIATION JOURNAL* for January 14th, p. 38. Everything is of value that throws light on these most fearful cases. I do not know anything more perplexing than to see a woman fainting and yawning, shivering and sinking, at the commencement of her labour, when you cannot detect any external cause. In this case, there had not been any hæmorrhage previously. She was supported with cordials, and pains encouraged, till the child was born

dead, but evidently only a short time dead; and, after the placenta, came a great clot, as large as itself. The faintness continued some time.

As this case presented some features of interest, I may be allowed to reprint its history, with the remarks which I made upon it, from the *Medical Times* of January 18, 1851.

"I was called, Nov. 20th, at 1 o'clock A.M., to attend Mrs. A., aged 26, with her second child. She had been complaining since 11 P.M.; pains increased; head presenting, and pressing much on the linea of the os pubis, where she referred all her pain. At 2 o'clock, sudden fainting came on, with deadly pallor and cold extremities. On her rallying from this, by brandy, open windows, etc., the pains bristled up, and the uterus kept dilating, but was interrupted frequently by the faintness, which kept recurring without any external hæmorrhage till 3 o'clock, when she had a fearful rigor. She rallied again, and became less faint, but complained loudly, and begged for chloroform, which I was ultimately obliged to give her, with great benefit, till her child was born at 5 o'clock A.M., without any unusual detention in the vulva, but dead. Immediately on its exit, the placenta followed, accompanied by an enormous clot, as large as, if not larger than, the placenta; the subsequent hæmorrhage was not excessive, but the faintness was extreme; nevertheless, the uterus contracted well. The shock of her child's death, added to her exhaustion, made her case very critical for some time (she had lost her first child from erysipelas); she looked blanched and anæmic to a high degree, but gradually improved. On the third day, I was not a little alarmed and surprised to find her covered by a scarlatinoid rash, and the more so on being assured by her mother, then present, that she had had both scarlatina and measles. I had not met with this symptom before, and it was the more unaccountable from being unaccompanied by any appreciable fever; pulse 96. I ordered a mild alterative and cooling aperient, and left very uneasy. On returning to my study, I happened to take up the *London Journal of Medicine* for October 1850, and read that highly interesting and scientific article by Dr. Cormack, on 'The Entrance of Air into the Uterine Veins', wherein he alludes to some cases occurring in the practice of Dr. Simpson, in which the same rash appeared three days after delivery, but all followed by death; this made the matter more anxious for me by many degrees. Visiting early next morning, I found the patient improved; the rash still out, but *paler*; no febrile symptoms. I ordered a more generous diet, and it continued to disappear daily; and she ultimately did well, and is now able to appear at her dinner-table, little more than a month since her confinement.

"It is evident this was a case of hæmorrhage in utero, prior to the rupture of the membranes, owing to detachment of the placenta, and the rigor I suppose the evidence of the child's death; but I am not in possession of any facts that throw light on the cause of this detachment, except that she had felt debilitated of late from a continuous attack of influenza.

"I am induced to published this case by a remark I find in the ingenious article by Dr. Cormack, above alluded to, where he says, 'he notices his cases, in the hope that others will, when opportunities occur, make and record their observations.' I also refer to this phenomenon (the scarlatinoid rash), more with a view of adding a case to those already on record, than of proposing any theory regarding it. While I say this, I am not disposed to accept any of the theories at present propounded as at all satisfactorily accounting for this appearance; nor do I acknowledge any analogy, so far as I am able to judge, between the 'reddish tinge' of Dr. Warren and the 'scarlatinoid rash' of Dr. Simpson; the former appearing immediately after the evident entrance of air into the circulation, while the latter did not appear until two or three days after the shock of parturition, without any allusion to air having entered the uterine orifices. In my case, I think it is clear that no air entered the fainting commenced long before the mem-

branes were ruptured, and faintness only remained after the birth of child and placenta; besides, I had recourse to such mechanical support as made its entrance almost impossible. Nor do I see any analogy between a continuous, general, and gradually disappearing rash, as above stated, and the 'fitful suffusion of the face with a delicate blush, superseded quickly by extreme pallor.' To this latter, I think Dr. Cormack's theory of 'capillary relaxation' admirably applies; but, with all deference to such high authority, it does not satisfactorily account to my own mind for the former red hue. If I might venture a theory on the subject myself, I would remark, that I believe it to be connected with such a state of body as exists in low adynamic fever, or pure typhus, where there is a general lack of vital tone, depressed organic nervous system, and deteriorated circulating medium; all which were evident in Mrs. A.'s case. The rash disappeared on adopting a generous diet and mildly tonic plan; in a word, it appeared analogous to petechiæ or purpura."

The object of the subjoined tabular statement is to exhibit at a glance my mode of practice, and its success.

The mortality amongst children from all causes would be 1 in 10; but deducting the 16 accounted for above, it would be 1 in 75.

The proportion of twins is 1 in 62, rather below the

average, which, according to the hospital returns for England and Ireland, is 1 in 65. All occurred amongst the lower classes. I find the average among the higher classes yields 1 in 120, showing the influence the luxuries and refinements of highly civilized life possess in restraining fecundity.

I trust that my meagre report may soon be followed by others on a larger scale, so that ampler data may be obtained. It is quite evident, from the few published reports of private practice extant, that obstetricians differ widely in their method of practice. Let me give some examples of the differences to which I refer. Dr. Copeman, of Norwich, has used the rectis 108 times in his practice; I never employed it once in my life. Again, in reference to anæsthesia by chloroform, now that it has received the Royal assent, it would be interesting to know the experience of men in large midwifery practice regarding its use. Some, we see, consider it the greatest boon to suffering humanity, and a *sine quâ non* in midwifery; others, again, look upon it as a dangerous innovation, calculated to do infinite physical and moral damage. The ASSOCIATION JOURNAL of June 17th (p. 524) contains a paper by Mr. Beecroft, of Hyde, stating his doubts as to its being beneficial in any case. He commences his communication by the startling acknowledgement and strange fact, that the journals teem with the praises of anæsthesia in midwifery, and contain nothing against it. An exception is said to be needful to form a rule; so Mr. Beecroft wishes to supply one. My experience of this practice is very limited; but, so far as my experience goes, it is in its favour. I never knew it do any harm: I seldom refuse it; and I never press it. How any practitioner can dispute its value, its necessity, in instrumental cases, when wisely administered, I cannot understand. On the other hand, I am no advocate for producing that state of total insensibility which some think necessary, but which appears to me to be an unsafe and uncalled for experiment. If judiciously given, and its effects watched, it is possible to attain insensibility to pain, without the loss of consciousness. This plan I am in the habit of adopting. The first time I became aware that such a state was possible was when attending a lady in the country, some years ago, with her seventh child. The pains were vigorous and effective, and with each she inhaled chloroform; and, when the head was pressing on the perinæum, she joked me about her pains, as being insufficient for the work. Soon after she had made the remark, the child was born, and the mother would hardly believe that she was delivered. I believe that the advantages as well as the dangers of chloroform consist in its purity, and in the mode of its administration.

Shaw Street, Liverpool, June 22nd, 1853.

BIBLIOGRAPHICAL NOTICES.

THE TREATMENT OF OBSTINATE ULCERS AND CUTANEOUS ERUPTIONS ON THE LEG, WITHOUT CONFINEMENT. By HENRY T. CHAPMAN, F.R.C.S., late Surgeon to the St. George's and St. James's Dispensary. Second edition, pp. 156. London: 1853.

Any information which enables us to treat with increased success a very troublesome and unsatisfactory class of cases, is at all times acceptable; and, on opening Mr. CHAPMAN's book, we are led to expect some real help in the treatment of ulcers of the leg, from the following remarks at p. 4:—

“Notwithstanding my conviction of the general superiority of those modes of cure which are founded on the principle of support, it is very far from my intention to advocate an *exclusive* reliance upon them. In obstinate cases of this troublesome complaint, I am too well aware that we require all the artificial aid which can be brought to bear against it. I have accordingly endeavoured to show that, if we would avoid frequent disap-

pointment, instead of attempting to apply any one plan of treatment to all its varieties, our remedial measures must be selected, combined, and adapted, from the varied and ample resources of past and present experience, to meet the special exigencies of each individual case.”

The author first examines the Sources of the Intractability of Ulcers on the Leg. These sources of intractability are local and constitutional; these are rarely in operation singly, but are most frequently combined, especially in nearly every case of chronic ulcer; the local causes, if not always preponderating over the constitutional, commonly outlasting them.

“The *peculiar* intractability of ulcers on the leg is clearly traceable to the dependent position of the lower extremity, which, by impeding the free return of blood in the veins, places the capillaries of the ulcer, and of its immediate neighbourhood, in an unfavourable condition for originating and carrying on the reparative process. If the case is left to nature, . . . to the atonic character naturally impressed upon an ulcer by its locality will be superadded inflammatory, irritable, or callous features; which, being regarded as characteristic of distinct varieties of the complaint, have been laid hold of as grounds of classification.” (p. 11.)

The distinctions which Mr. Chapman recognises are those of *Indolence*, *Irritability*, and *Callousness*. He regards, however, the first of these alone as a constant and essential character of ulcers of the leg; the others being merely engrafted on it.

The most simple characteristic, then—but a very troublesome one to the surgeon—is that of indolence, or simple want of activity in the reparative process. The capillaries of an ulcer in a depending part are acted on by the *vis ætergo* of the heart and arteries on one side, and by more or less pressure from the blood in the veins on the other side: hence the circulation through them is impeded; they become dilated; and the balance between vascularity and reparative deposition is disturbed. This condition of redundant vascularity is readily detectible by the naked eye, in the loose semitransparent granulations of indolent ulcers.

There is, however, as Mr. Chapman rightly points out, another cause which influences, though negatively, the formation of indolent ulcers.

“Sufficient importance does not appear to have been accorded, by any writer on this subject, to the circumstances in which the capillaries of a granulating ulcer in a depending part are placed by the loss of an elastic envelope like the skin. The acceleration of the blood's motion during rapidly repeated muscular efforts, when an alternate action and reaction between the muscles and the skin are kept up, speedily emptying the superficial veins, is sufficient to prove that the skin, by its resilience, must afford an essential aid to the circulation in the veins. And since, as long as it remains entire, it thus exercises a constant and uniform control over forces tending from within outwards, it is obvious that the vessels of a granulating surface, deprived of the support of this elastic integument by a breach in its continuity, will have nothing but the feeble resistance of their own walls to oppose to the delicate pressure from within.

“If the distension thus produced be not artificially counteracted, the nearly stagnant blood being quite unfit for any healthy operation, exudation of plastic lymph ceases, the new vessels themselves are gradually absorbed, and the sore at length acquires an indolent or atonic habit.” (pp. 17-18.)

Irritability in ulcers is next treated of, and is referred to over-distension of the nerves, which are “not merely incapacitated for the healthy discharge of their share in the reparative function, but are kept by it in a greater or less degree of morbid sensibility”. Dr. Billing supposes that morbid sensibility may sometimes be caused by inflammation of nerves; and this, Mr. Chapman says, appears to be a very probable explanation of persistent irritability, as is shown in the tense and fiery look of the surrounding skin, where the pain is mostly felt. But this “tense and fiery look” points to a general inflammatory process in which the nerves are involved along with other tissues, rather than to any special morbid action on their part. In this way we would explain the morbid sensibility of ulcers to arise, in a very great measure, from the passive participation by the nerves in the lesion of nutrition, whether

that be characterised by deficient action—indolence, or by unequal and perverted action—inflammation. Some observations of the author confirm us in this view. He says: "There are no invariable external indications of morbid sensibility; it is manifested by ulcers of a great variety of aspect; and, as long as it continues, proves an almost certain obstacle to healthy secretion and granulation." The substitution, in the latter clause, of the words "indicates a deficiency in", for "proves an almost certain obstacle to", would be an improvement.

Callousness is next examined. The deposit of coagulable lymph, in which the majority of ulcers on the leg are imbedded, is regarded by Mr. Chapman as

"A barrier to check a too free egress of blood from the sub-jacent vessels, and to secure the yet fragile walls of the new capillaries from plethora or rupture. It may thus be looked upon as a special provision of nature, to guard against the mischief to which the vessels, engaged in an attempt to repair a breach of surface in a depending part, would otherwise be constantly exposed. In ulcers prone to hemorrhage, I have almost invariably noticed that this deposit is absent; and, when its absorption has been effected by art, nearly all sores bleed as soon as the bandage is taken off, if the foot be allowed to hang down." (pp. 21.)

It is when callousness proceeds beyond the protective point, that it becomes mischievous, by impeding the necessary supply of blood. This condition and that of irritability are often combined.

Varicose ulcers next form the subject of some very sensible remarks. The author would reject this term as applied to a class *per se*; observing that the impediment to the circulation in cases of varix is merely a higher degree of that which retards the cure of indolent ulcers in general, and indicates nothing more than an increased disposition to atony. As to the question whether ulcers are caused by varix, Mr. Chapman writes, in a foot-note at p. 25:—

"In upwards of one hundred cases, I carefully inquired into the mode in which the ulcer commenced; and not more than five broke out by pimples, vesicles, or scabs, generated by varix. Several originated in the rupture of a varicose vein, and a few were ascribed to cutaneous eruptions of various kinds, upon both trunk and limbs. The remainder, amounting to full eight-tenths, were the result of external injury; varix being present and absent in about equal proportions."

A little further on, we find the following remarks:—

"Although the extension of inflammatory action from the veins to the subcutaneous and cutaneous tissues may sometimes give rise to ulceration, and stamp it with a very distinct aspect, I think we are scarcely warranted in assuming that any source of intractability exists, in ulcers directly caused by varicose veins, different or distinct from that which predominates in the indolent species. At any rate, we shall gain nothing, in a practical point of view, by retaining the distinction between sores caused by varix and those which are merely complicated by its presence; since, precisely the same means which cure the latter will prove equally successful with sores of the peculiar character above described.

"But I am disposed to go farther still, and contend that we ought to discard the term *varicose ulcer* from our classifications altogether. If it be restricted to ulcers caused by varix, a large proportion of cases, the cure of which is rendered more difficult by this complication, will not be included under the term. If, on the other hand, it is applied to every sore accompanied by a varicose state of the veins, it will necessarily comprehend all other classes of ulcer in turn. All this confusion will be avoided, and the nature of one of these cases will, I conceive, be defined much more simply and accurately, if, instead of employing a designation so vague and general, we substitute for it the phrase, indolent, irritable, or callous ulcer, complicated by the presence of varix."

TREATMENT. If any notions have been formed by the perusal of the foregoing pages, of the sufficiency of local treatment alone, they must be entirely dissipated by the first section of that department of Mr. Chapman's book which is devoted to treatment, and which occupies much the largest portion of the work.

The author very opportunely places in the foremost rank

some remarks on Ulcers of the Leg, the Intractability of which is traceable to Constitutional Causes. In atonic ulcers, the indications are to remove sources of irritation arising from deficient excretion, and improper diet, and then to administer tonics. In prostration arising from addiction to ardent spirits, or in the cachexy induced by insufficient food and confinement to unwholesome dwellings, large doses of quinine surpass all other remedies. The diet should be nutritious rather than spare.

In obstinate chronic cases, various remedies have been empirically employed, as mercurials, sarsaparilla, etc. In 1837, Mr. Skey brought forward opium as an almost specific remedy in the "chronic or callous ulcer affecting the legs of old persons." Mr. Chapman has not met with so much success as Mr. Skey in treating by opium alone the class of cases to which the latter gentleman refers: but he has found opium far more serviceable "in sloughing ulcers, the result of debility". The dose given by Mr. Skey seems to have been sometimes eight drops of the tincture twice a-day; but more frequently half a grain of the extract night and morning, which dose may be gradually increased to two grains.

Irregularities in the menstrual function, and the question of the effect on the health of the cure of habitual ulcers, are next examined. In opposition to the commonly received view, Cowper, B. Bell, Boyer, Underwood, Whately, Baynton, and Sir E. Home, all express their conviction that chronic ulcers in aged persons may be healed with safety. Mr. Chapman is more cautious.

"Since in many cases a manifest influence is exerted upon other maladies by these sores, I make it a rule to inquire into the state of health previous to their outbreak; and if it should distinctly appear that the patient has enjoyed a respite from more serious disorders coincidently with the existence of the ulcer, I should feel some hesitation in attempting its cure.

"If, on the other hand, the health has suffered materially in consequence of the local disease, no scruples need be entertained on that score. And where doubt exists, in order to guard against any possible mischief from healing them, it is advisable to continue to pay very close attention to the preservation of the general health; and whenever a tendency to plethora, or any determination of blood to the head, exists, the establishment of an issue in the arm would be but a measure of prudence. Some few instances have come to my knowledge in which, this precaution having been neglected, death has followed within a short period of the cure of the ulcer, under circumstances which have been sufficient to raise a well-grounded suspicion that the *post hoc* may not, in all such cases, have been mistaken for the *propter hoc*." (pp. 43-44).

In the next section, we find the Treatment of Ulcers on the Leg which are rendered Intractable by Local Causes.

John Bell, in his *Principles of Surgery*, vol. i, p. 97, humorously wrote as follows:—

"It is impossible to be serious when we enumerate the thousand remedies which have been applied to ulcers. . . . Ulcers have been dressed with precipitate, calomel, alum, vitriol, zinc, verdigris, pulvis sahijna, and other devilish drugs; they have been powdered with sugar, chalk, charcoal, asafetida, and other innocent drugs; they have been plastered with turpentine, balsams, mel mercuriale, decoctions of walnut-leaves in sugar, (which Belloyte protests to be a medicine so powerful that no ulcer can resist it). . . . They have been squeezed into good humour by compresses and firm bandaging, strong sticking-plasters, plates of lead upon the shins, sponges, cakes of Paris-plaster, etc., or bladders have been fixed about ulcers full of fixed air, carbonic air, vital air: What is there, indeed, which has not been tried?" (pp. 46-7).

Mr. Chapman very properly points out that the depreciated estimation of the value of the remedies recommended in the treatment of ulcers arises, not from their inefficiency, but from their universal and indiscriminate employment. He would rather accept all means of cure that may be offered, rating them at what they are worth when brought to the test of experience.

The non-permanency of the cure of indolent ulcers ascribed by Dr. Underwood—and with him Mr. Chapman closely agrees—to the confinement of the patient in a horizontal position. Dr. Underwood remarks "how

prejudicial it must be to general health for a person accustomed to labour and exercise to be confined for a length of time in an inactive state, and the greatest part of it in an almost horizontal position"; and he further says: "The frequency—I had almost said the constancy, with which large and old ulcers on the legs are found to return, is greatly owing to their having been healed in the horizontal position." Not only do we agree with Dr. Underwood that confinement acts injuriously through the general health, but we believe that nutrition and reparation are locally impeded by the withdrawal of the stimulus afforded by the moderate exercise of the part. It is not exercise, but exhaustive over-exercise, that does harm.

The author examines the merits of the plans of treatment recommended by Baynton, Underwood, Whately, and Scott; and believes that the plan of plaster-strapping has been abused. He acknowledges that it has some merit; but points out some serious drawbacks from its utility.

"1. It is totally inadmissible in those extreme cases of irritable ulcer where the morbid sensibility is so acute that no degree of pressure can be borne, until by suitable measures it has been removed, or, at any rate considerably mitigated. 2nd. There are other varieties of chronic ulcer,—rare, certainly, and giving no indications of their refractory nature beforehand,—in which, by no skill or care, can the sore be brought to heal under the operation of the strapping. And, 3rd, in ulcers furnishing a very copious discharge, and *à fortiori*, when that discharge is of an acrid character, the plaster-strapping, whatever may be its composition, being impermeable, diffuses it over the sound skin in the neighbourhood of the sore, thus frequently giving rise to very troublesome erythematous inflammation and excoriation, retarding its cure if it does not actually increase the dimensions of the ulcer. Under similar circumstances, unctuous dressings are likewise very apt to produce the same vexatious consequences.

"Instances are not unfrequent of severe mischief ensuing from the partial or careless application of plaster-strapping; and the danger is, of course, enhanced in proportion to the degree of tightness with which it is applied." (pp. 61-62).

Mr. Chapman discards ointments in the local treatment of ulcers. He employs water dressing as the basis, and, when necessary, uses solutions of sulphate of copper, sulphate of zinc, etc., according to the requirements of the case.

We now come to the author's description of his own plan of bandaging.

"The sore being dressed with a piece of lint cut to its shape and dimensions, and dipped in cold water, or in one of the lotions just specified, the limb is to be strapped with wet bands of linen or calico, precisely in the same manner as Messrs. Baynton and Scott applied adhesive plaster. The bands for this purpose should be from two to three inches in width, and from twelve to sixteen or eighteen in length; stout enough to prevent them tearing easily, but not too thick. Strips of coarse Mull muslin, indeed, are preferable in many cases to either linen or calico. Following Mr. Scott's practice, the middle of one of the shorter and narrower of these bands, previously soaked in water, is adjusted a little above the heel, whence the two ends are brought forward over the ankles, drawn rather tightly, and crossed upon the instep. The middle of another is placed beneath the sole of the foot, its extremities brought up firmly over the instep, and laid down smoothly one upon the other. A third is applied, like the first, from behind forwards, but a little higher; and thus, ascending the leg, the process is repeated with the rest of the bands, each one in succession overlapping the upper half of that below it, until the limb is firmly and evenly cased to the knee, or, at any rate, to a point several inches above the seat of the ulcer.

"Unless, however, much tendency to oedema be present, the ulcer be complicated by varix, or a higher degree of compression than that requisite for giving support be thought expedient, it is unnecessary to strap the limb to such an extent. In ordinary cases, three or four straps, according to Baynton's original plan, are all that will be required. Over them a calico roller is applied, the greatest attention being paid to its equable adjustment; so that the pressure be distributed evenly over the entire surface. At the small of the leg, and round the ankle, in oedematous limbs, the straps and roller are apt to fall into plaits, which furrow and gall the skin. To guard against this inconvenience, the hollows round the malleoli should be filled up by compresses of wet lint.

"That part of the bandage over the ulcer should be moistened from time to time with cold water containing glycerine, or with Goulard's lotion. The frequency with which the cold affusion is practised, must be regulated by the temperature of the part, and the state of the patient's feelings; heat, uneasiness, and irritability, being at once relieved by it. The age and temperament of the patient, as well as the season of the year, ought also to be taken into consideration; some caution being necessary to avoid the application of too low a temperature—not alone to prevent the extreme consequences which may ensue, the extinction of all vitality in the newly formed structure, but to guard against the vitality being reduced to a degree incompatible with vigorous reparative action. Evaporation should, therefore, in many cases, be controlled, by enveloping the part of the limb affected in a sheet of oiled silk. In proportion as the ulcer advances towards cicatrization, the affusion is required much less frequently, and in the last stage of the cure, (excepting as a prelude to the removal of the dressings,) it may often be altogether dispensed with.

"If the ulcer secretes abundantly, the dressing must be repeated daily, although the wet lint will absorb much of the discharge. Very shortly, however, under the action of cold and other astringents, loose, shining, semitransparent granulations become compact and red; and a thin and copious secretion diminishes in quantity and improves in quality, rendering a daily renewal of the dressings quite unnecessary; and, after a time, this necessity becomes still more rare. In several of the cases hereafter recorded, an interval of three, four, or even five days, sometimes elapsed between each dressing, not only without any interruption to the onward progress of the ulcer, but to its manifest acceleration." (pp. 78-80).

Under this plan, Mr. Chapman says, the cure proceeds favourably and expeditiously; but he is ready to admit that when a sore has been reduced so far that plaster-strapping can effectively approximate its opposite margins, recourse to Baynton's proceeding will often considerably expedite the cure.

In very obstinate cases, the author recommends the employment of counter-irritation, by means of a small blister at the upper part of the leg, dressed daily with a piece of Brown's or Albespeyre's cantharidine paper, of about the size of a shilling.

In the treatment of inflammatory ulcers, Mr. Chapman would apply leeches—not to the surrounding parts, but to the ulcer itself; and, as a preparation for all other local treatment, he would have the skin for some distance all round the sore carefully cleansed with mild soap and warm water.

The treatment of irritable and of callous ulcers is described by Mr. Chapman; but we must pass over this portion of the book, recommending it as likely to afford instruction.

We extract the following from the remarks on Prognosis.

"Under the section relating to the treatment of constitutional sources of intractability, the propriety of healing ulcers on the leg, under certain circumstances, was reviewed, and the conditions in which it might prove dangerous pointed out. There are some few ulcers, again, the permanent cure of which may almost be regarded as an impossibility; and in forming our prognosis neither of these contingencies should be lost sight of. The circumstances which may render it impossible to heal a chronic ulcer may be either constitutional or local; but impediments of the former class can scarcely enter into our estimate of the prospects of effecting a cure, as we can only infer their insurmountable nature after the failure of repeated attempts to remove them. There are, on the other hand, some peculiar local conditions, recognisable at a glance, which, when present in an extreme degree, deprive us of all hope of accomplishing a sound and lasting cicatrization.

"One of these conditions is an extensive destruction of the fascia, sheathing the muscles and tendons of the leg; which accident exerts an injurious influence over the healing process in the following manner. As the granulations shoot up from the surface of the exposed muscles or tendons, the base of the cicatrix necessarily becomes firmly adherent to them, and is consequently liable to be dragged upwards or downwards by their slightest movement. Cicatrization, nevertheless, will proceed until a tense ring of new skin has been formed, and at this stage the process is suspended altogether, every muscular effort being attended by severe pain. Perfect repose in the recumbent

position, and blistering the circumference, may, perhaps, succeed in overcoming the difficulty, after Baynton's plan or my proceeding have utterly failed; but, whenever the patient begins again to use the limb, the drag upon the newly formed structure is so incessant, that the cicatrix rapidly gives way, and the ulcer breaks out afresh. From the nature of the case no kind of bandage can guard against a relapse; but much of the pain will be removed by the operation of the blistering liquid.

"Measured by the same standard, the cure is completed by means of wet strapping in less than Mr. Whately's average period, although, perhaps, not so speedily as by Baynton's method. An ulcer of a few months standing and of moderate dimensions, unattended by aggravating circumstances, may generally be healed in two or three weeks. Where unfavourable conditions are present, it may require as many months. But time becomes a matter of less importance, when the patient is placed, almost from the commencement of the treatment, in a position comparatively free from pain and inconvenience; the limb being so effectively supported that, with ordinary care, he is enabled to pursue his usual avocations, without interrupting the progress of the cure. A degree of facility, moreover, in the application of the wet straps, may soon be acquired, which will qualify him, in a great measure, for undertaking the management of his own case.

"The most perfect cicatrization can never be deemed quite secure, unless the bandage be worn for some time afterwards to maintain the cure; an object which will be much advanced by soaking the straps in a solution of chloride of lime.

"Extreme cases of the disease, which have obstinately resisted all other treatment, may yet give way to a combination of the bandage with the recumbent position; but in chronic ulcers healed under rest, I have not found that commencing the use of a bandage, when the patient begins once more to exercise the limb, affords any great security against a relapse." (pp. 134-39).

UTILITY OF THE BANDAGE IN THE TREATMENT OF CUTANEOUS ERUPTIONS ON THE LEG. *Eczema rubrum* on the legs may or may not arise from varix.

"As long as the part affected is dependent, the capillaries of the inflamed integument are in a state of congestion but little inferior to those of an ulcer in the same region. This is easily demonstrable, either by the aid of the microscope, or by the simple experiment to which I appealed at p. 10. A patient labouring under eczema on the leg has but to assume the erect posture, and from every pore of an excoriated surface, comparatively dry while the limb is laid up, a gush of serum will take place, to such an excess as amply to justify the popular name for this variety of the complaint—'weeping leg'.

"The first step, accordingly, in the treatment of eczema of the lower extremity, which is enjoined upon the patient, is confinement to the bed or sofa; and in the acutely inflammatory stage this is always advisable, often indispensable. Many local remedies, moreover, of established repute, can scarcely otherwise be properly applied. But we have the same difficulty to encounter in carrying such an injunction fully into effect, as in the case of ulcer on the leg. Some few may submit partially to the discipline; for the many, absolute rest is impracticable. Even when it can be fairly put in force, the capillaries of the inflamed integument will derive very considerable additional benefit from support; and no kind of bandage is so well suited to afford it as the wet strapping. At the same time it answers most commodiously both as a protective and as a medicated dressing. For patients whose position in life constrains them to be more or less on foot, there is no alternative. Acute eczema, under such circumstances, almost invariably runs on into the chronic form, when, as Dr. Neligan truly observes, 'it is most rebellious to treatment, years sometimes elapsing before it can be subdued'.

"As, in its acute stage, eczema is a highly inflammatory disease, antiphlogistic remedies must necessarily constitute the basis of the treatment. In the average run of cases, early abstraction of blood, by leeches, will suffice to check its violence and shorten its active career. Should an ulcer exist simultaneously with the cutaneous eruption, three or more may be applied at once to its surface; and as a considerable amount of blood will flow from this source, if the leg be immersed in warm water, the practice will seldom fail in arresting inflammatory action. I have heard patients make the remark, that they have watched the red excoriated area gradually becoming paler under the loss of blood occasioned by a single leech. If there is no breach of surface, I apply them without hesitation to the skin; feeling little apprehension of the leech-bites ulcerating, as long as the limb is properly supported by the bandage.

"The part affected should then be bathed for some time with thin gruel, and afterwards enveloped smoothly, from the foot upwards, with bands of linen, or patent lint, dipped in Goulard or glycerine lotion, warm, and a roller applied with moderate firmness; the whole bandage being subjected to warm affusion long and repeatedly. Weak alkaline solutions are the topical applications generally recommended, but are not, I think, superior to the lotions just mentioned, or even to warm water. When tested, the profuse discharge will, like healthy serum, still be found alkaline; and simple dilution appears to diminish its acrid quality, while the moistened lint, by absorbing it as it is poured forth, prevents its mischievous diffusion. A weak lotion of nitrate of silver (gr. ij. ad ʒi), brushed lightly over the inflamed skin, will sometimes prove highly useful, but is not adapted to all cases.

"The bandage need not be renewed more frequently than once in twenty-four hours; and, at each dressing, the scales should be cleared away as thoroughly as possible without irritating the sensitive cutis. If a single application of leeches should not cut short the inflammation, they must be repeated until that end is fully attained. In one very aggravated case, the subject of it being a robust man of sanguine temperament, I bled from the internal saphena vein at the knee, to the amount of ʒviii., with the best effect.

"Although saline aperients and diaphoretics are most essentially subservient to the local antiphlogistic remedies, no class of medicines seems to exert a more decisive influence over acute eczema than diuretics. A combination of acetate of potash, nitre, and vinum colchici, is one which I have largely prescribed with marked benefit.

"In the chronic stage, emollients and antiphlogistics must give place to astringent dressings, such as creasote lotion, lotio rubra, or solutions of chloride of lime of graduated strength; preparations which I prefer to ointments, having frequently seen the latter disagree. Mild tonics, and a more generous diet, are now permissible.

"As the skin regains its healthy character, the bandage will not require renewal oftener than every second or third day, but still ought to be moistened occasionally with some astringent lotion. Finally, it should not be abandoned prematurely, more especially when the veins of the limb are varicose." (pp. 144-148).

In a foot-note at the last page, Mr. Chapman states that Mr. Startin, in 1846, recommended the application of a bandage in what he termed "*Eczema inveteratum crustatum*"; a variety of the disease very common on the lower extremities.

Mr. Chapman has not disappointed us in the hope we had formed, of meeting with some sensible observations on the treatment of ulcers. He is evidently not one of those who first write a book on a certain disease or class of diseases, in order that they may gain experience therein; but he has written out of the fullness of his experience. While bringing forward strong proof of the correctness of his own views, and of the efficacy of the plan which he recommends, he does not fall into the error of indiscriminately depreciating the opinions or treatment of his predecessors: but allows to each remedy its due amount of merit.

We can conscientiously recommend all surgeons who are annoyed with having to treat obstinate ulcers of the leg—and who are not?—to peruse Mr. Chapman's work, and to make trial of the plan of treatment which he describes.

NATURE AND TREATMENT OF DEFORMITIES OF THE HUMAN FRAME: Being a Course of Lectures delivered at the Royal Orthopaedic Hospital in 1843, with numerous Notes and Additions to the present time. By W. J. LITTLE, M.D., Physician to the London Hospital, &c. pp. 412. London: 1853.

Dr. Little has brought together from all sources the existing knowledge of the profession regarding the Nature and Treatment of Deformities; and he has also contributed not

* After the cure of chronic eczema, it is often quite as necessary to adopt the precaution of keeping up counter-irritation, for some length of time, in old cases of ulcer.

a little information from the stores of his own abundant and enlightened experience. The book is illustrated by one hundred and sixty pictorial sketches and diagrams, and is accompanied by an excellent Index.

MORAL-SANITARY ECONOMY. By HENRY M'CORMAC, M.D., Consulting Physician to the Belfast General Hospital. 12mo., pp. 150. London: 1853.

THE subjects discussed by the author are Female Degradation; Employment; Education; Household Culture; Criminal Management; Physical Training; Clothing; Food; Drink; Air; Drainage; and the Prevention of Disease. The spirit of Christian philanthropy, which pervades this volume, commands the highest admiration; and the performance, as a whole, is calculated not only to enlighten the public upon some most important and pressing questions of social economics, but likewise to excite to the adoption of means for accomplishing reforms. The price of the work is only one shilling; so that its possession is placed within the power of the working clergy, and many other benevolent and useful members of the community who have not facilities for giving liberal orders to their booksellers.

The plague spot and the gnawing canker of the moral and physical health of society—female degradation—is truthfully depicted, with the view of suggesting the method by which it may most readily be moderated or cured.

"FEMALE DEGRADATION.

"Marriage is God's ordinance, true preserver of woman's dignity, and equaliser of the sexes. Its violation has induced no small amount of moral degradation and physical wretchedness. The purest relations should subsist between the sexes. Multitudes live in unnatural isolation or open profligacy. Individuals whom no child is destined to call parent, swarm around. When vice is rampant, social progress must needs be stayed. The spectacles presented in great towns, with the scenes in hospitals, nay, the very youth of courtesans, are unspeakably distressing. Tait, Talbot, Ryan, Duchâtelet, relate particulars that vie in infamy. There are even whole districts, where parentage is said to precede marriage (*Local Sanitary Reports*, p. 393.) Everywhere the terrible deficiency in house accommodation, without adequate separation of the sexes, convenience, or privacy, aggravates these distressing evils.

"Numbers, as a writer in the *Westminster Review*, July 1850, p. 393, has remarked, are lost from sheer unknowingness, yet women cannot too soon learn to respect themselves, too promptly to repel insidious advances. It is impossible, declares a memorable writer, to describe the good engendered by self-control. 'Mistress of my imagination,' she observes, 'I remained true to principle, and, despite of temptation, contracted aversion for every solitary animal gratification.' Roland, *Appel à l'Impartiale Posterité*, Paris, 1792, p. 99.) Destitution, exclaims Duchâtelet, is the principal source of female prostitution. Of 5,183 courtesans in Paris, 2,000 had been cast off by relatives, 80 resorted to vice to procure sustenance, 280 impelled by shame had forsaken their homes, while 2,118, abandoned by their seducers, had nothing else to turn to (*De la Prostitution dans la ville de Paris*, i. 92.) 'Want, absolute want,' avers Mr. Helpe, 'is the main cause of this sin on the woman's part' (*Companions of my Solitude*, p. 92.) One of Mr. Mayhew's cases was that of a young seamstress whom utter penury had driven to pollution! There were trowers' sewers whose story was the same. Three shillings weekly were the miserable earnings of one who, with scalding tears, swore by her Maker, that she was pure up to the death of her surety! A poor creature declared on her soul, that the low price of labour, after infinite anguish, had alone constrained her to outrage modesty in order to procure food for her infant and herself. Nay, Duchâtelet states that there were women who had subjected themselves to this greatest of indignities in order to obtain subsistence for their else perishing parents and children!

"Negro slavery is very bad, but is it so bad as this? Yet this, and if it be possible worse than this, was borne testimony to by a number of suffering creatures who had obeyed Mr. Mayhew's invitation to recount their distresses. The chill winds in which the light garments of the midnight wanderers flutter, are hardly so chill as the cold world which plunges them in misery, then leaves them to perish in it!

"To thousands often nurtured with care, the only resource

is prostitution!' (*Morning Chronicle*, November 16th, 1849.) Women, in truth, are too much excluded from remunerative pursuits, from intellectual, nay moral, culture. Yet who can doubt, were undue impediments removed, that they would greatly excel? How emphatically do such omissions bespeak the low material status of our time? Not only should women be shielded from toil, but from the very possibility of want-induced degradation. Every path of literature, science, art, should lie open to them. Agnesi and Somerville in mathematics, Dacier and Carter in classics, with the bright galaxy of literary female celebrities, sufficiently proclaim their attainments and their powers.

"Everywhere throughout Prussia and Austria, women and girls may be seen drudging beyond their strength and the delicacy of their sex, clearing ditches, bearing huge baskets of fruit and vegetables, while men and lads, abstracted from the ranks of industry, lounge about in uniform, devouring the produce which their mothers and sisters, reduced to the condition of slaves, have realised.' (*Times*, Nov. 1, 1850.) Women abound in the French rural districts, haggard, attenuated, overwrought; while men, in hundreds of thousands, in the flower of their age, are kept up doing nothing, in the *casernes* of the Republic! We arrogate, in many respects justly, a superiority over pagan times; but did women then perform the labour of animals, as Bonstetten has told us they do in Italian Switzerland? Did they displace pack-horses as in Irish bogs, or break stones as Lord Byron saw them do in Greece, and as I myself have seen them do in Ireland, to this day? Or did they toil, filthy and wretched, doomed, as Clarke informs us, 'to the labour of men', up the long shaft, as in Swedish iron-mines, or drag loaded waggons, as until recently, in English and Scottish coal-pits? In America, every white woman is by courtesy a lady, but every black woman, in certain States, an animal and a slave! The grand distinction between savage and civilised life, I take it, resides in the tender consideration and gentler usage of women; yet veriest savages hardly treat women as I have described. Whatever be the hardships of the wilderness, they do not at any rate include the misery of prostitution!

"So long as this sad calling shall subsist, it should not be obtruded on the public gaze. By rendering it less facile, we at least diminish the crime. Women, youths even, may not safely pursue their lawful callings after dark. It is then that crapula, intoxication, vice, range without control. Streets are serried with police, yet modesty can hardly pass without a blush. Ryan, in his work, *Prostitution in the City of London*, relates particulars incredible to all who have not sounded the dark depths of human folly and debasement. Wretches, for whose iniquity no epithet is too vile, prowl, it seems, over the continent, to entrap victims for the London bagnios. A procurer is a monster by many degrees worse than the ghouls of the East, or the fabled vampires of Hungary. These, it was alleged, devoured the bodies, sucked the blood of their victims; whereas the procurer preys on the souls of hers! It is monstrous that females, often under age, should be lured with impunity to their doom, as that women, to secure a morsel of bread, should be consigned to the basest of all indignities. Of 1,200 seamstresses at Mr. Mayhew's second meeting, but four, it was stated, had under-garments, fifty-eight only had blankets, 151 had no beds, while the rest were in states of varying wretchedness! Honour, then, to those who withstand an ordeal so dire; and succouring compassion to those who yield.

"None of the asylums, none of the societies, for the protection, so termed, of young women, afford adequate sustenance and relief. Right eloquently has the dreary contrast between the daughter of luxury and the starveling needle-woman, been portrayed in the plate styled '*Pin and Needle Money*', in *Punch*. Hood's '*Song of a Shirt*' will perpetuate his name, long after the evils which his gentle spirit would redress have ceased. Why do not women themselves come forward in the angel mission of rescuing their kind? 'Something', Margaret Fuller affirms, 'might be done, if they would but try, fearing none save One whose eyes are purer than to behold iniquity.' (*Women in the Nineteenth Century*, p. 103.) What, then, if women were to enter into a solemn league to stay the degradation which so sorely besets their kind? Were there but a single Elizabeth Fry, Sarah Martin, or Mrs. Chisholm, in each several parish, this great good work would soon be in process of accomplishment.

"But vast as are these evils, they are not the only ones. Hideous disorders attend the unlawful commerce of the sexes, blighting the infant unborn, inducing inevitable ruin and decay. The skin, throat, bones even, do not escape. The so beautiful structure of the eye is doubly implicated, first in syphilitic iritis,

then in gonorrhoeal ophthalmia, that wretched malady which, as I conceive, has housed itself in Egypt, and infests our race. These disorders are at once acute and chronic, nor does one attack yield exemption from another. The evil is urgent, the very remedy is dire. Medical writings are rife with details only to be surpassed by the yet more horrible reality. Very children even are found in the lock hospitals of great cities; while millions, it may be affirmed, are lavished on the wages of debauchery. No lady, Tait asserts, dare venture abroad after dark in the streets of Edinburgh! But is Edinburgh the only city? He counts at one-fourth, the annual mortality among the female victims to prostitution, this so brutish vice, and utter violation of the loftier destinies of our kind! (*On Magdalenism*, 2nd edition, p. 220.) Brothels and low lodging-houses, if possible worse, subsist by hundreds in all our large towns; and there, prostitution and syphilis, the sin and the soil, go hand in hand together. The native population of the beautiful isles of the Southern Seas are undergoing rapid extinction, owing to the ravages of a dreadful malady!

"In London, huge city, abode of so much wealth, such unaffected goodness and untiring energies, there are houses where boys and girls, already thieves and prostitutes, abide together promiscuously—abodes where chastity is bought and sold for a night's lodging, and where uncleanness, brutality, and crime, riot without check and without delay! There, too, unhappy women eat the bread of infamy, clamouring night and day for victims, sacrifices to the anguish and slavery which they feel, and pain would inflict in turn. As night closes in, sights abound too plainly indicative of the social ruin that ravens around, sounds which more forcefully than any words declare the dreary fall and sad prostration of the utterers. Forty thousand illegitimate children, according to the Registrar, are yearly born in England, besides those who perish, sometimes mother and child together, through the execrable arts of hired aborters! In London alone, two thousand women, it is said, annually replace those who die amid their sin and misery.

"Prostitution, male and female, is the plague-spot of our time! 'Every trace of human dignity and moral grandeur must needs be swept away by this gross perversion of the sex from its divine ends.' (*Winslow's Journal*, Jan. 1851.) If there be a truth more certain than another, it is that chastity, 'fountain of inward nourishment, keystone of the moral arch, parent of correct taste, the blessed principle of which religion and a high moral tone are the lovely fruits,' should be the rule and measure of our lives. It is vain to palter! The few short hours of this brief existence are by thousands handed over to dissoluteness and vice. Surely every means should be resorted to, at once to stay the vice of prostitution, with the thrice-cursed evils that spring from it. 'Were there more love in the world, these things could not be. The man who has once loved any woman, would, one would think, have more tenderness for all; for love implies an infinite respect, shows for a moment the possibilities of our race.' (*Companions of my Solitude*, p. 119.) Assuredly, we are bound to furnish a crust to our suffering sisters, the perishing daughters of our race. 'L'homme,' exclaims Comte, in a chapter of singular beauty and power, 'doit nourrir la femme.' (*Politique Positive*, p. 248.) But man does not nourish woman as he ought; hence unhappy creatures defile themselves for bread. But the body is given for God's uses, and not to be defiled. We need, in truth, an education superior to the present, as virtue and peaceful industry are superior to vice and idle profligacy, a lofty spiritual, adequate industrial training. We cannot well bestow too much attention on the culture of the young, to surrounding them with a moral atmosphere, which shall negative all corrupt, realise all sweet and precious influences—

'Flowers that never can in other climate blow!'

"Would only that the great realities of this life, and of the life to come, could be fitly instilled among the poor. Heedless of risk, the physician, on whom this merciful ministry seems mainly to have devolved, sits by the pallet of the sick and sorrowing, wipes away the sweats of death, and utters, as the physician may fitly utter, words of consolation and peace to the wistful, anxious sufferer, resigned to die, yet fearful of the mighty change. There is not, in truth, a den of veriest infamy where there is not scope for charitable offices, souls to be rescued, creatures brought over to some enduring perception of their temporal and eternal destinies. How precious are the effluences of the great hierarchy of letters, which, could they only be brought home to all, would go far to redeem the material tendencies of our time. Would that, freed from spiritual error and misconception, there were yet other Wesleys, Whitfields,

Fletchers, Kirwans, Oberlins, Benezets, Neffs, Vincent de Paul, and Fenelons—men who descended like angels of light into the arena of the world, and struggled with the principles of evil for the immortal souls of perishing men. Were there only adequate spiritual culture, there would be fewer drunkards, robbers, thieves, prostitutes, and vastly less disease. Industry and economy would take heart, and drive vice and profligacy from the field. Intemperance and prostitution are eating into the vitals, consuming the virtues of the poor. The daily press abounds with details of inconceivable ignorance and moral turpitude. Oh, if man have greater power than woman, it is not given him to cast her into the bottomless pit of social perdition and loathsome decay! Her capacities, however different their expression, when duly cultivated, are on a level with those of the opposite sex. She even excels, it may be, in the loftier emotions and angelic affections of our nature. But let man act as he may, woman is bound to be her own special guardian and protectrix. Virtue does not reside in brawn and muscle! A woman, as such, is not weaker in all that constitutes the real excellence of humanity. There is not a reason, save want of adequate culture, why all women should not be chaste as was Lucretia, spotless as are the virgins of Raphael. But then, their education should be such as befits wives and mothers, and not merely the sorry drudges of worthless men.

"In all desirable lofty respects, the education of women should be the counterpart of that of men—the freest scope in literature, science, art, with everything relating to household and personal requirements. All the hard work in the world is for men's stalwart arms to accomplish. Women can be very much better employed in offices of charity, training the young, filling all hearts, and adorning all homes. Let us enfranchise them indeed, from brutal servitude, ignorance, and sin. Any other enfranchisement is neither possible nor desirable. Every effort should be made to prevent, were it a single one, from lapsing into vice, folly, wretchedness. Each several woman has a claim to tenderness, respect, and sustenance, from the whole race of man. Truly, as has been said, chastity is a plant of delicate, precarious growth. It is a virtue whose absence in one sex unavoidably deteriorates and degrades both. It concerns every woman, every man, then, that there should be no female vice. But man himself must submit to the restraint. 'Vertu imposée aux femmes,' exclaims a writer of note, herself a woman, 'tu ne serais jamais qu'un nom, tant que l'homme ne prendra point la moitié de la tâche!' But each well-principled, well-constituted man and woman, must feel alike interested in averting stain, were it from the lowliest, humblest of the sex. Then, by a mother's surpassing tenderness, a wife's unselfish devotion, a daughter's untiring fondness, a sister's deep affection, let each manly heart and striving intellect contribute their best influences towards reinstating the sex in their honoured lofty place, and so avert the horrors, the anguish, and the pollution, from which all alike should essay to shield them." (pp. 1-8.)

The following passage touches on a more pleasant subject; and it contains hints on a variety of topics which may be usefully considered in hundreds of households to which this Journal is a weekly visitor. How widely spread, and yet how extreme, is the error of supposing that the affluent can alone possess the means of efficiently educating their children. Cheap schools are, we believe, always bad schools; but home is the best soil for commencing the successful culture of the mind; and let those whose restricted means prevent them from being able to delegate the nurture of their children at a tender age to the stipendiary pedagogue, be consoled by the reflection that home is the normal shelter of the young, and that in no other soil can the affections be cultivated, and in no other soil can a healthful expansion and an ennobling culture of the intellect be so well secured. Again, how common is it to suppose that a frugal board is synonymous with semi-starvation; whereas cheap cookery is the best cookery. In fact, it is contentment and cheerful industry, and not wealth, which sweeten life.

"HOUSEHOLD CULTURE."

"In England, yet more in Highland Scotland, Celtic Ireland, the people appear to have mainly lost the art of the wholesome, agreeable preparation of food. In England itself, the amount of fleshmeat has been much reduced, though Fortescue, Lord Chief Justice in the reign of the Sixth Henry, dilates on the peasants' opulence, their ales, meats, and warm, abundant coverings. (*Thornton's Plea for Peasant Proprietors*, p. 75.)

Nor is this the only record of the rough sufficiency of the times, ere the peasant was reduced to his present low estate. Numerous food ingredients are neglected by working men, careless or ignorant as to their preparation. No dish, however, should be prepared, were it for the humblest, of which the most fastidious would object to partake. The curry of the East Indies, pepper-pot of the West Indies, Irish stew, French 'pot-au-feu', New-England chowder or fish stew, Spanish 'olla' or 'puchero', with fish, flesh, fowl, fruits, vegetables, bread, ales, wine, are significant of comforts which too little abound, where so greatly needed, on the tables of the poor! A treatise, at once practical, brief, perspicuous, for that large class to whom comfort, health, economy, are objects, is what is wanted. Cookery for the Million should dilate on meats, drinks, revising national usages, selecting the best. Negroes, for example, cook their rice just thirty minutes in boiling water, 'croquant', indeed. Kid, pork, lamb, oysters, turtle, fowl, venison, they prepare admirably well; while their meat and vegetable soups are of peculiar excellence. Turks and Moorsmen have 'pilafs' of rice and mutton, 'kouscous', or the sun-dried granules of watered flour, steamed over meats—messes really worth gold. (*White's Constantinople, Letters from Barbary.*) There are valuable suggestions in the maze of French cookery, more especially as relates to the 'pot-au-feu', 'premier bouillon', or stock, the 'roux', both white and brown, for enhancing the flavour of meats; the judicious introduction of onions, and even wines, for the same and other purposes; the mode of boiling larded and other meats, as mutton, fowl, with a very little water, and as much stock; the perfect economy of fuel, of scraps, and, in short, complete avoidance of waste. (*French Domestic Cookery*, London, 1825.) So long, indeed, as food can be rendered wholesome and agreeable, or the very reverse, the art of preparing it must remain essential to human health and well-being. Unvaried, flavourless fare, does not satisfy the palate, or, in fact, meet the desirable requirements of healthy organic life.

"The convertibility of aliments is a question of moment in the economy of food. If a hundred-weight, more or less, we shall suppose, of roots or greens, realise but a pound of increase in a stall-fed ox, and yield twenty pounds of milk, half as nourishing, perhaps, as meat, when given to the cow, it would seem to suggest how much more profitable were a larger consumption of milk, than the slaughtering of animals merely for their flesh. The judicious admixture of animal fibre, however, imparts substance and flavour to a vegetable mass. Here, I conceive, lies the secret of the cheap, effective sustenance of the people, removed alike from carnivorous excess, as from meagre insufficiency.

"Rumford, in his *Essays*, Liebig, in his *Chemistry of Food*, show how a moderate degree of warmth, sufficiently prolonged, serves better than hot haste, to prepare meats for wholesome, agreeable participation. The best cookery, indeed, is also the cheapest. Ten, or, as Rumford has it, seventeen times as much fuel is wasted in open fires, the fuel consuming itself to waste, as would suffice in receptacles closed so as to obviate radiation. Vessels of silver, tin, porcelain, glazed or enamelled ware, fitted into other vessels heated by hot water, steam, or gas, would render cooking processes cleanly and effective, as they are too often the reverse. To the inventive genius of Appert we owe, it seems, the notable discovery that fish, flesh, fowl, fruit, vegetables, milk, in vessels hermetically sealed, immersed in a solution of the chloride of lime, or simply salt and water, raised to the boiling point, will keep illimitably. Fruit, meats, roots, vegetables, may be dried according to Masson or Murdoch's processes, in stoves, at a low temperature, then subjected to pressure. Soaked in water, before being cooked, they are found to retain all their original flavour. Yolk of egg, or the chopped fibre of animal or vegetable substances, might be incorporated with flour, and, after being baked, consigned to close vessels. Biscuit of this description, really meat-biscuits, would, I conceive, prove more consonant with the wants of the animal economy, than the meat-biscuits, so termed, of Liebig, in which the juices, and not the meat fibre, are included. The loss of substance in boiled meats, soups or stews excepted, should almost exclude them from economic cookery. Paste envelopes, boiled or baked, preserve the juices and the flavour of meats, fish, flesh, and fowl, to admiration. Buckwheat pastry, as also puddings, of which a sort of salmon and buckwheat are the ingredients, is much used in Russia. Fish forms an excellent soup or stew, and is thus used in many places. On the banks of Newfoundland, the hard-working fishermen live for months on cod-fish fried with pork. Polenta or ground maize, also macaroni, the food of Neapolitan Lazzi, yields admirable nutriment. Lentils, the 'ervalents' of advertisers, though avail-

able in stew and otherwise, do not merit all the eulogiums which have been lavished on them.

"We must begin at the beginning, reform the defective training of the young from the very first. A school for cooking is among the excellent suggestions in *Cook's Journal*. But schools for household and industrial culture should subside everywhere. A writer in the *Mechanics' Magazine* comments on the total absence, in school and governess advertisements, of any indication of domestic knowledge! After urging the adoption of schools for pastry, clear-starching, plain needlework, patching, darning, millinery, dress-making, cookery, nursing, he adds: 'Let it not be conceived that knowledge in homely concerns either destroys beauty, renders a woman less able to shine in society, or to obtain distinction in the higher branches of literature. Very numerous are the examples which might be adduced of the combination of beauty and talents with the knowledge and practice of domestic concerns.' (No. 1513, p. 119.) Wilson's sewing-machines, now constructed in thousands at Watertown, Connecticut, will indeed effect a sort of domestic revolution, and prove a mighty boon to thrifty housewives.

"Her Majesty has set the good example at Windsor. In the Finchley School, the girls wash, dry, and iron clothes, which they bring home, with a neatly written account. They also prepare a dinner weekly, for their own use. At Belfast, the girls make, mend, sew, wash, without pretermittting general culture. There are industrial schools in nineteen different localities in Ireland, as well as others in England and Scotland. Many of these are under the direction of ladies of rank and station, who, if they thus everywhere exercised their gentle, genial influence, would confer an unspeakable boon on the suffering, destitute creatures of the sex, 'nam frequens imitatio transit in mores'; and giver and receiver are doubly blessed!

"Industrially and intellectually, in truth, women are everywhere under-educated. From the Registrar's returns, half the women of England, it appears, are unable to write their names at marriage. Thus, the mothers and first instructors of mankind are themselves uninstructed. All women Dr. Winalow would have learn some useful employment or art, whereby, as wives and mothers, they might add to their own and their husbands' means. The two millions unmarried Englishwomen, half a million in excess of the other sex, he would not leave 'dependent on friends and relatives, jostled out of the ranks by men competing for effeminate employments.' (*Psychological Journal*, January 1850.) A lofty, general culture, extended to both sexes, would best enhance their usefulness, and augment the resources of all. If man be uneducated, he drags down woman, his inseparable companion and dependent: and if woman be so, she but helps to reduce her associate to the same low level!

"In 1806, the States of the Duchy of Nassau, convinced of the evils of neglect, decreed that twice a week the female children of each several commune should assemble under a competent salaried matron, for instruction in sewing, knitting, darning, washing, housekeeping, in short, order, economy, neatness, cleanliness, first elements of all civilization and refinement. 'It leaves a melancholy impression', observes a friend, writing from this same Nassau, 'to find so much more comfort, enjoyment, and apparent social superiority, on a soil so far inferior to our own. Nowhere have I seen the ragged, squalid misery, of our own poor!' Dean Dawes informs us, that the Rev. Mr. Fanshawe, of Southampton, proposed to fit up a house under an experienced matron, where girls should be provided with industrial occupation, and enabled to become happy, self-supporting members of society. The state, however, should enforce universal industrial, secular culture, nor leave it to the issues of casual benevolence. The sculptors of old were said to disclose the ideal man beneath the marble covering; but no marble ever equalled the angelic ideal that niches in man's soul, and which needs but culture to develop into glorious reality! Theotoki unites with the author of *Home Education* in urging early culture, female culture in particular, in the country. He would not keep girls in towns, where a foolish, pedantic training, destroys their delicate youthful beauty, and even impairs their happiest tendencies. In the country, nature puts forth her strength, and shows what she is able to accomplish in favour of this precious portion of humanity. 'Dans la campagne la nature étale ses forces, et montre tout ce qu'elle peut en faveur de cette portion précieuse de l'humanité.' If in the country, however, it should be under genial auspices, and not as in France, where, as Aimé Martin has said, crushed by excessive effort, women wither ere their time, 'écrasées sous les travaux des hommes elles vieillissent avant l'âge.' 'I know not how', exclaims Taylor,

speaking of female education, 'to avoid affirming the peculiar suitability of a country residence, the insulated country house, with its frugal elegance and interior comforts, its garden of sweet, gay, perennial enjoyment, and ample spaces for all purposes of homestead exercise and recreation. For there, and there only, can children be kept in high mental activity, without too frequent recourse to books, where copious acquaintance can be made with nature, along with robust health, a late development, and the invaluable habit of day by day looking to the mind's own elasticity for enjoyment.'

"Miss Mitford, in charming language, instils almost every feminine excellence. Miss Edgeworth, Miss Sedgwick, severally, are replete with practical instruction. Would that their chastening influence, and that of other admirable female writers, were extended to every, the humblest member of their sex. As Mrs. Somerville, in her *Physical Geography*, has expressed it, it would realise a culture that should stamp itself on the features, and prove perennial with the race! Margaret Fuller insists on the better culture of women, as 'temples of the immortal intellect'. Very earnest, and very admirable too, are the appeals of Mary W. Godwin, in her *Education of Daughters*. The better influences of Christianity, which have gone far to exalt the proletariat and the slave, would also, if enforced, elevate the condition of woman. For all women should be virtuous, accomplished, capable; else how are they to secure their material, spiritual interests, or those of their offspring? Rousseau, Aimé Martin, Pemberton, everywhere, indeed, proclaim the great celestial truth, that the wise and loving mother is, and must be, the source of every good to her child!" (pp. 34-39.)

INFLAMMATION OF THE BREAST, AND MILK-ABSCESSES. By THOMAS WILLIAM NUNN, Surgeon to the Western Dispensary. pp. 52. London: 1853.

THIS little work is arranged in three sections, which treat respectively of the symptoms, causes, and treatment of Inflammation of the Breast. There is no striking originality in the book; but we can recommend it as containing a very readable abstract of what is at present known concerning the above-mentioned diseases. We shall hope to see, at some future time, an enlarged edition of Mr. NUNN's essay, containing the fruits of his further experience and reflection.

REPORTS OF SOCIETIES.

EAST KENT AND CANTERBURY MEDICAL SOCIETY.

SESSION 1852.

[The following Report is intended to present a concise abstract of the most interesting cases and papers communicated to this Society during the session of 1852: similar cases being grouped together as much as possible.—J. R.]

PULSATING TUMOUR IN THE UPPER THIRD OF THE THIGH; LIGATURE OF THE EXTERNAL ILIAC SUCCESSFUL. BY H. DENNE, ESQ.

CASE. George H. Percy, aged 30, a sailor, of middle stature, rather thin, and having a sallow complexion, was admitted into the Kent and Canterbury Hospital, on April 20th, 1847, with a pulsating tumour in the upper and anterior part of the left thigh. Some time before his admission, whilst using great exertion on board ship, he felt something give way in the thigh; and about a month before he came to the hospital he perceived a small swelling in the situation where he had felt the pain, but took no particular notice of it. The swelling, however, became larger and more painful, so as to cause him to apply to a surgeon in the Isle of Thanet, who immediately sent him to the hospital.

On examining the thigh, a tumour, of undefined limits, but apparently as large as a man's fist, was found in the upper and front part of the left thigh. Its form was rather conical, the point being directed inwards; a strong *expansive* pulsation was felt in it in every direction, and a bruit was heard on applying a stethoscope to it. Pressure on the femoral artery completely stopped the pulsation. The man complained of cold in the part, and was greatly comforted by the application of a hot poultice. During the few weeks he was in the hospital, prior

to the operation, the swelling slowly increased; but on visiting him on the afternoon of May 9th, Mr. Denne found that a sudden change had taken place since his last visit. The thigh in the neighbourhood of the tumour had become considerably enlarged, and was discoloured, the limits of the tumour being lost in the general swelling. A consultation of the medical staff was summoned the same night; and in consequence of the swelling approaching close to Poupard's ligament, it was deemed expedient that the external iliac artery should be immediately tied.

Mr. Denne cut down upon the artery in the usual manner, and experienced no difficulty in putting a ligature round the vessel. The pulsations in the tumour ceased immediately after the operation. The limb was enveloped in spongio-piline, and its temperature was never much below that of the other. The patient's recovery was uninterrupted. The ligature separated on the twenty-ninth day (June 7th), and on the fortieth (June 18th), pulsation was felt in the anterior and posterior tibial arteries. The general and increased tumefaction noticed on the 9th of May, subsided soon after the operation; but the tumour did not continue to decrease in the proportion usually observed in aneurism, after ligature of the artery that is involved: so that, when he was discharged from the hospital, September 3rd, there remained a tolerably firm tumour, about two-thirds of the size of the swelling that existed when he was admitted, and retaining the same form.

POPLITEAL ANEURISM SUCCESSFULLY TREATED BY COMPRESSION. BY H. DENNE, ESQ.

CASE. G. P., aged 36, a tall, and rather stout healthy-looking man, a gate-keeper on the South Eastern Railway, was admitted into the Kent and Canterbury Hospital with a popliteal aneurism, in March 1852. About seven years previously, the right leg was removed below the knee in consequence of a severe injury about the foot, from a railway truck passing over it; he recovered well, and had since used a wooden leg. In October 1851, he visited the Great Exhibition, when he was obliged to walk much and very fast, about four miles in an hour. About a week or ten days after his return home, he felt great pain in the under part of the knee, and considered it was from a sprain; but upon examination he found a swelling, of the size of his finger; since then the swelling had gradually increased. He first felt pulsation in the swelling about Christmas; but it has never been so painful as to oblige him to rest the limb.

A tolerably firm elastic swelling occupied the ham projecting posteriorly, extending over the inner side of the lower part of the femur, and encroaching upon the calf of the leg, so as very much to limit the power of flexing the leg. A very forcible and *expansive* pulsation was perceptible in the entire extent of the tumour, but more especially on the inner side. A loud bruit was detected by the stethoscope; and upon interrupting the circulation by pressure upon the femoral artery at the groin, the swelling diminished considerably. The patient complained of pain extending down the calf of the leg to the ankle. During the unavoidable delay that occurred, in obtaining the required apparatus from London, the tumour increased in its upper and inner portion; and the bruit, which had been more distinct on the inner side, became more audible in the centre of the posterior part. The pain which he had experienced upon admission diminished very much under the rest and quiet to which he was subjected. The apparatus used was that known as Dr. Carte's pelvic apparatus for compression of the artery at the groin, with the ring-tourniquet for effecting pressure upon the artery below.

The instruments were applied on April 18th, at twelve o'clock. The pulse was then ninety-four, and rather weak. The pressure on the artery in the thigh was so fixed, as to stop the pulsation completely. The pulse very soon rose to 108, and became fuller, it however fell to ninety by the evening, and varied during the subsequent treatment between eighty and ninety-six. The pain from the pressure had become so severe by 2 P.M., that it was necessary to relax the tourniquet on the thigh and to apply the pressure upon the groin. It was found that the integument was discoloured, where the wooden pad of the instrument had pressed; and shortly after, slight vesication formed on the surface of the bruised skin. After this, pads of lint were introduced between the integument and the compresses of the tourniquets with good effect. The man was cheerful and intelligent, and interested himself so much in the plan of treatment, that, during the latter part of it, he was entrusted with the adjustment of the pressure, and permitted to relax the screw of one instrument, and to readjust that of the other, whenever the pressure became too painful. He bore the pressure of both instruments for a

period varying from four to six hours. Although, each time the compresses were screwed down, the pulsation was completely checked, yet, shortly afterwards, a feeble thrill, and sometimes a fair pulsation could be discerned in the swelling. This was more particularly the case when the compress on the groin only was in operation. In addition to the occasional pain from the instruments, the man experienced pain, and sometimes numbness, in the foot and ankle.

On the 19th he was thirsty and rather feverish, partly from a sleepless night and constipated bowels. He was relieved from these symptoms in the course of the day, by a free action of the bowels. During the night of the 19th he slept comfortably, at intervals, for three and four hours at a time; and for seven hours the pressure was maintained by the ring tourniquet.

Between 4 and 5 P.M., of the 21st, about *seventy-six hours* from the commencement of the treatment, the patient suddenly felt a severe thrilling pain about the upper and inner sides of the knee-joint, which lasted nearly half-an-hour, and extended down the leg to the toes; a sensation of throbbing about the part was also experienced. Shortly after this pain had subsided, the screws were relaxed, and the swelling was found to be quite free from pulsation, which never returned. During the three days of treatment, the tumour was perceived to become more consolidated, slight pressure was continued four days longer, and then the apparatus was removed and a bandage applied.

He was made an out-patient on May 18th; a firm swelling the size of a fist still remaining in the ham. During the three months that he continued an out-patient, the tumour slowly diminished.

TRAUMATIC ANEURISM OF THE ULNAR ARTERY: TREATMENT BY GENERAL COMPRESSION: RECOVERY. BY J. REID, ESQ.

CASE. S. W., aged 37, married, was admitted into the Kent and Canterbury Hospital, November 18th, 1851. She was of a spare habit, and of a nervous and anxious temperament. Two months before she was admitted, when correcting her son at dinner-time, she directed a blow with her hand at his head. At the same moment, the boy raised his hand with a knife in it, in order to protect himself; her arm came in contact with its point, and a deep wound, about an inch and a half above the wrist-joint, on the ulnar side, was made in her right forearm. Blood immediately issued in a jet, and spirted about the room; but by the aid of her neighbours the bleeding was stopped. About an hour and a half afterwards she showed the wound to a surgeon, who, finding there was no hæmorrhage, brought the edges of the wound together. The arm became painful and swollen at the seat of the injury, and about three days afterwards, the whole arm, from the fingers to the elbow, became very much swollen and tender. This condition lasted for a week, during the whole of which time the pain was very severe. Antiphlogistic measures were adopted, and the arm was poulticed; and at last the patient was bled from a vein in the affected arm and experienced great relief. The general tumefaction subsided, leaving a circumscribed swelling, which was presumed to be an abscess, and which it was proposed to puncture, but the patient objected. It was subsequently discovered to be an aneurism.

When she was admitted, there was a swelling immediately above the wrist, about as large as a goose's egg, without very distinctly marked limits. It pulsed strongly in all parts, the beating being perceptible even to the patient. A loud bruit was also communicated to the ear. The tumour appeared to extend under the superficial muscles of the arm. The cicatrix of the wound was situated on the inner side of the swelling and, for some distance around it, the surface presented a dull slate colour, the integument feeling much thinner here than elsewhere. The movements of the hand and fingers were crippled; and there was no sensation in the ring and middle fingers. A thick compress of lint was placed over the swelling; the fingers were bandaged, and a roller was firmly applied to the forearm, as far as the elbow. The pressure could not be borne longer than for four hours, and then it was slackened. At the end of four days, though the tumour seemed a little smaller, the pulsation remained as strong as before. The fingers were now more firmly bandaged by strips of adhesive plaister, two pieces of sheet lead folded in lint were fitted to and placed over the tumour, and a solid narrow cylindrical pad was placed as nearly as possible in the course of the ulnar artery, along the upper part of the forearm, and firm pressure with a bandage was applied over the whole. The pressure was borne for six hours, when it was necessary to relax it by cutting some of the turns of the bandage. When the bandage was removed, at the end of forty-eight hours after its application, the pulsation had ceased in the swelling. The bandage and compresses were reapplied, and at the

end of three days were removed. The tumour was then found to have decreased; but upon close examination it was thought that there was a feeble pulsation, such as the recurrent circulation might produce. An additional pad was placed between the aneurism and the wrist, over the ulnar artery. No pulsation could be subsequently felt, and the swelling contracted. The compresses were gradually removed, and the bandage only was retained. When the swelling had diminished to the size of a small walnut, it remained stationary for some weeks; but in the last week in December, the fore-arm became painful and slightly swollen. By rest, cold lotions, and aperient medicines, this subsided, and the remains of the aneurismal sac became soft and fluctuating, so that it was expected that suppuration had occurred in it. The swelling, however, slowly decreased, and ultimately entirely disappeared, the only trace that remained of the injury, being a cicatrix with some induration in the surrounding parts. The hand continued in a crippled state when she was discharged.

Mr. REID thought that much of the successful issue of the case was due to the pressure produced upon the ulnar artery by the cylindrical pad above the aneurism, and regarded the case as one confirming in some degree the treatment of aneurism by compression of the artery between the aneurism and the heart. Had this mode of treatment failed, it was intended to have employed pressure upon the brachial artery by a ring tourniquet.

The patient was again in the hospital in 1852, for dyspepsia and neuralgic pains in the face and head. Although the movements of the arm had improved, those of the hand remained in much the same state. A slight increase of power in the movements of the fingers, but more especially in the wrist, took place whilst she was in the hospital, and there seemed a prospect, when she left it, that in course of time the hand would again become useful.

[To be continued.]

ASSOCIATION INTELLIGENCE.

TWENTY-FIRST ANNIVERSARY MEETING.

The Anniversary Meeting of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION will be held at Swansea, on Wednesday, the 10th, and Thursday, the 11th of August. The particulars were published in the JOURNAL for May 27th, p. 470; and it is intended to reprint them, with additions, in the numbers for July 8th, and August 5th.

ANNIVERSARY BRANCH MEETINGS ALREADY ANNOUNCED.

The following is a summary of official notices contained in the numbers for June 17th and 24th, to which we refer for details.

BRANCH.	DAY AND HOUR.	PLACE.
Monmouthshire and South Wales.	July 6th, at 12 o'clock.	Public Rooms, Bank Buildings, Chepstow.
Metropolitan Counties.	July 19th, 4 P.M.	Brunswick Hotel, Blackwall.

NORTH WALES BRANCH.

The Report of the Annual Meeting did not arrive in time for publication this week. It shall appear in next number.

EDITOR'S LETTER BOX.

THE MEDICAL PROFESSION AND THE CRYSTAL PALACE.

LETTER FROM JOHN FORBES, M.D., D.C.L., F.R.S., TO THE EDITOR.

SIR,—The astounding announcement made in your last JOURNAL to the effect "that six hundred and forty London medical practitioners, among whom there are many of the most eminent men of our profession", have signed a petition to be

presented to Parliament against the opening of the new Crystal Palace at Sydenham, on Sundays, has induced me to request the favour of your inserting the subjoined extract from a work recently published by me.* The remarks were originally addressed to the clergy, but it appears that they may be now applied to 640 medical men! Alas, that it should be so! Alas, that men of science, and above all physiologists, actually conversant with the causes of disease and the habits and sufferings of the labouring classes, should have so far forgotten that noble philanthropy and that tender humanity which form the very essence of our profession!

After perusing the strange and most illogical petition printed in your pages, I can hardly feel that any apology is necessary for the very hard words contained in the extract, even now when they are directed to a quarter where, but for the evidence supplied by you, I could never have dreamed of their applicability.

I am, etc,

JOHN FORBES, M.D.

"Without claiming for the labouring-classes in England indulgences of this kind+ on the Sunday—which are, indeed, foreign to their habits and inclinations—surely we may claim for those of them, at least, who reside in large towns, the privilege of seeking for relaxation in the open air of the country, whether carried thither by land or by water, by omnibus, boat, or rail. It is truly at once humiliating and melancholy to observe—in these later years, when we might reasonably expect a more philosophical consideration of such subjects—that there is a growing disposition among the clergy and the upper classes generally in England, and still more in Scotland, to curtail such simple and natural enjoyments of the poor on their only holiday, Sunday. To say nothing of the necessity of such relaxation on the score of mere bodily health, the advocates of this system seem entirely to overlook that principle of man's nature, which renders the occasional remission of activity necessary for the perfect exercise of all voluntary functions, and, most of all, the functions of the brain.

"Everybody who has had anything to do with the instruction of others, or who has ever attempted the acquisition of knowledge in his own person, is fully aware of the great benefit derived from occasional interruptions in the course of study, and knows that progress is positively retarded by over-long persistence in mental exertion. Religious exercises and study form no exception to this general rule; overdone they are ill-done. The brain is just as apt to be exhausted, and the thoughts to become weakened and confused, in religious pursuits, as in any other mode of mental occupation; and the results will be just as inadequate and unsatisfactory in the special category referred to, as in any form of secular study. A jaded and muddled mind can no more do justice to religion than it can to any profane subject.

"The same parties also persist in ignoring the fact known to all others—that the great majority of the working classes of large towns will not attend church more than once, if so much, even if constrained to remain, during the whole Sunday, within the circle of their weekly labours; so that the cause of religion would be no gainer under the restrictive law contended for; while the subjects for whom it is proposed to enact it, would be deprived of the most precious opportunities of improving their bodily and mental health, and so adding to their happiness, through the indispensable medium of air, exercise, and relaxation. On the contrary, both religion and morals, and, consequently, society at large, would be positively great losers thereby, inasmuch as both reason and experience assure us, that the temptations to sottish indulgence of every kind, leading to vice in all its forms, would be infinitely greater in the state of constrained idleness and listlessness into which the poor must necessarily be thrown, in the case supposed, than they can be amid the inspiring, active, and healthy excitements which, to a smoke-dried citizen, are the spontaneous and necessary results of a rural excursion.

"Few schemes, I venture to affirm, have ever been broached more false in principle, or calculated to be more injurious in practice—nay, I should think, less in harmony with the profoundly tender and merciful views of human nature, promulgated by the great author of Christianity himself—than that which would forge additional chains, over and above those necessarily incidental to their lot, to keep in perpetuity the children of labour within the walls of their great civic prisons. It is to be hoped that no British legislature will ever be found

so indifferent to the claims of humanity, as to sanction any measure that could lead to so disastrous a result.

"It is indeed difficult for a man only moderately versed in the knowledge of human nature, in all its parts, to conceive how doctrines issuing in such monstrous practical absurdities as these, could be entertained by men of education. The explanation can only be this, that though men of education, they are not duly instructed in a knowledge of much that appertains to man's physical and moral nature, and that, in their unenlightened zeal to promote mere technical religion, they overlook the very foundations of morality and virtue. They are like the charlatans in physic, to whom I have so often referred for illustration; they rely on the mystic action of a nostrum of imaginary power, instead of employing means that embrace the whole disease and heal it radically."

THE MEDICAL PROFESSION IN RELATION TO MEDICAL POLICE.

LETTER FROM H. L. SMITH, Esq., TO THE EDITOR.

SIR,—I am anxious to submit to the profession another outline of an "Act of Parliament", to reform the franchise, advance morality, and bring the members of the medical profession into the sanitary regulations of the country, with power and influence.

I am, etc.,

H. L. SMITH.

Southam, June 1853.

I. Whereas, it appears from reason, experience, and vital statistics, that SIN on the one hand, and MORALITY on the other, have both their first principles, which work effects downwards to death, or upwards to life, with as much regularity and certainty as the first principles of mechanics, chemistry, optics, or any other science. And that the first principles of sin are, disobedience to the Maker's will, violence, cruelty, pride, idolatry, covetousness, lust, hardness of heart, and unbelief; all of which are deeply grounded in the heart of the liar, thief, and apostate, who believes that he possesses anything of his own.

II. Whereas, the first principles of morals are, belief in God, purity, chastity, faithfulness, humility, kindness to one another, and obedience to the natural laws and revealed will of their Maker, all practically carried out by those true, honest, and faithful Christians, who know that every possession, gift, or talent, is not their own, but is from God; and intrusted to them to be made holy, by being consecrated to the good of man for the glory of God!

III. And, whereas, it appears to have been of old time designed by God, that the pious, zealous, and self-denying Christians of this kingdom, should, in the latter days, be His working servants and chief agents in bringing all the other nations of the earth to the knowledge of Him, so that they may be subjected to His will, and the personal government of His Son.

It is for this purpose we now enjoy the blessing of the increase, till every village overflows, and every port is filled with our people, for the occupancy of the waste places of the earth, demanding a supply far beyond that derived from the older nations, who have had the same blessing and lost it, by neglecting to attend to the things that are to be found in the "tents of peace and righteousness", which are annexed conditions and stipulations for holding the blessing permanently. Witness Greece, Rome, the Northern Hive, Portugal, Spain, and France, who have possessed, and have been deprived, in geographical order from east to west, of this blessing which we enjoy, but which we shall certainly lose, unless we take warning by their punishment. Therefore, it is necessary that we supplant as quickly and as unostentatiously as we can, the selfish and sensual, who return our representatives, by giving the orderly and the moral a share in the elective franchise for this purpose.

It is therefore enacted, that every father shall, for every child born in wedlock, have one vote for a representative in Parliament, provided he has adopted the following prospective measures of "providing for his own household", one of the first principles of Christian duty.

1. That he has secured medical care for himself and family, by having been admitted as a member of a "self-supporting provident or Victoria dispensary".

2. That he has also provided an income, in sickness, by subscription to a "sick club", equal to two-thirds of his average earnings when in health.

It is further enacted, that he shall have two votes when he

* Memorandums, made in Ireland, in the autumn of 1852.

+ Dancing, etc., customary with the Irish, as with other Catholics.

child that he has educated, until it is fifteen years of age, provided he has also secured an income, by assurance, for his own old age, and a legacy to his wife of £50 on his death.

Now, Mr. Editor, let us consider what would be the effects of this simple but comprehensive law:—

1. By giving the man, as father, the right of voting in right of his successors, he would look to principles and ultimate ends, rather than to temporary expedients, as electors now do.
2. It would encourage the holy state of matrimony, honourable in all men, but necessary in the children of God, to fill up the dreadful vacancies made by the discontented, by wars, famines, plagues, and apostasies, by which they are working out their own exit here, and final punishment hereafter.
3. It should lead to the general establishment of "self-supporting dispensaries", improved "sick clubs", and a vast increase of "insurance business" of all kinds.
4. It would destroy medical quackery, and the imputation of extortion amongst the qualified.
5. It would insure increase of peace and righteousness, of loyalty and patriotism, in the densest populations.
6. Medical men would be paid for time and skill, instead of drugs.
7. Vaccination would be generally adopted.
8. It would place the Elective Franchise on a moral basis, which would grow downwards in society, and bear fruit upwards in its government.
9. Lastly, and which must be my apology for this preliminary exposition, it would introduce medical men into the Home Office with power, because through Parliament; and when we recollect that there is no person, substance, animal, vegetable, or mineral, and that there is no change, condition, or accident, no causes, terrestrial or astral, but are brought under the notice of medical men, we may expect, that even more than any others, they would be able to look forward and provide for the invisible and exalted, the good, the right and truly peaceful, from their long practical habit of viewing the visible and the tangible, and their knowledge of God, and their love to mankind would grow up together, and would not be divorced by the gilded devices of palaces.

VARIETIES OF THE PUFF-BALL.

LETTER FROM B. W. RICHARDSON, Esq., TO THE EDITOR.

SIR,—A reviewer, in the last number of the *Gardener's Chronicle*, criticises me smartly, but very justly, for having neglected, in my paper "On the Anæsthetic Properties of the *Lycoperdon Proteus*", to indicate clearly the plant the properties of which I have described.

It ought to have been stated in my paper, that the term "*lycoperdon proteus*" has been used to describe several kinds of puff-ball, and that the puff-ball which has been used in all my experiments is the *lycoperdon giganteum*.

You will oblige me greatly by allowing this necessary correction to appear in an early number of your Journal.

I am, etc.,

BENJAMIN W. RICHARDSON.

Mortlake, June 27th, 1858.

CHLOROFORM IN LABOUR.

LETTER FROM EDGAR SHEPPARD, Esq., TO THE EDITOR.

SIR,—The question of the exhibition of chloroform in labour seems to me to lie in a very narrow compass. Equally narrow shall be the space of our Journal which, with your permission, I will occupy.

An answer to the following plain query, from the advocates of the production of anæsthesia, seems very essential: "Is it, or is it not desirable, to complicate a natural process?" Some one will reply: "You do not complicate—you simplify." I deny it. Such a position is altogether untenable. Is a man who is dead-drunk, "simplified" or "complicated" by his potations? And what advantage physically (if not morally) has a chloroformed over an intoxicated individual? Truly, I am unable to perceive any. No female for whom I have any regard shall ever, with my consent, inhale chloroform. I look upon its exhibition as a pandering to the weakness of humanity, especially of the softer sex. How much of this the annals of the last few years reveal! Electro-biology, Bloomerism, Cochinchina fowls (query, foolery?), Beecher-Stowe idolatry (there being plenty of room for sympathy with English slavery in the very

next street, my friend), table-turning, spirit-rapping, *cum multis aliis*, what are ye but records of English folly and gullibility? And shall we—we, the members of a noble profession—swell this catalogue of crazy weaknesses, by encouraging the use of an agent which has already slain many, and which renders every suffering man a *senseless* man? I am, etc.,

EDGAR SHEPPARD, M.R.C.S., L.S.A.

Enfield, June 24th.

[An answer to this and similar letters, will be found in an original article, from the pen of Dr. Simpson, to appear in our next number. EDITOR.]

NEWS AND TOPICS OF THE DAY.

CREDULITY AHEAD OF CHRISTIANITY. In 1845, one million and a half of the people of the continent visited in pilgrimage the "Holy Coat of Treves".

In 1850, the President of the "School of Pure Homœopathy" at Rio de Janeiro thus expressed himself, in commenting on the death of the Prince Alphonso of Brazil:—

"Science had a tendency to become Christian. But this moral revolution was incomplete, so long as medicine, that great necessity of man obnoxious to pain, remained given up to Hippocratic and Græco-Roman tradition—so long as historical conception continued, in a word, Pagan and material. It was then that appeared Hahnemann, the most astonishing, the most inspired of discoverers. Through him, Christian science became universal; and redemption descended from the dominion of sentiment to that of the ideas and of intelligence. . . . In order that the human race should renounce the worship of false gods, nothing less would serve than a *Deicide*. By a *Regicide*, allopathy was herself to indicate her last hour, and to show to all Brazil the monstrous consequences of their mischievous endeavours. Nothing could prevail against the efforts of the Most High. The Prince Alphonso was destined to perish, and we to bear witness to his death, in order that it might prove more useful to the world than has been the life of the greatest monarch." (*Doctrine de l'Ecole de Rio Janeiro et Pathogénésie Brésilienne*.)

In 1851, the Rev. T. R. Everest, Rector of Wickwar, preached, under sanction of the Bishop of London, a sermon in the Church of St. Augustine, Cheapside. In this sermon, he broadly stated, that "the Gospel could never have free course until the physical leprosy of man was cleansed, and his chronic tendencies cured"; and that this could be effected only by an application of the "medicine of love"—by preparing man for heaven by a course of globulistic treatment, commenced from infancy.

In 1853—a fortnight ago—the Archbishop of Dublin (Dr. Whately), long the patron of homœopathy and other systems of delusion and quackery, accepted the office of President of Dr. Elliotson's "Mesmeric Infirmary", vacant by the death of the Earl Ducie.

Thus are the wild speculations of charlatanic mysticism blasphemously proclaimed to be coequal with revealed religion, as necessary instruments for the temporal and eternal well-being of man. Thus is religion dishonoured through her ministers teaching "profane and old wives' fables", and forming in their own persons a loathsome alliance between Christian truth and the unbridled excesses of credulity.

HOSPITAL FOR WOMEN AND CHILDREN, AT LEEDS. In October 1852, a project for establishing a hospital for the diseases of women and children, at Leeds, the capital of the West Riding of Yorkshire, was brought forward by Mr. J. I. Ikin, of that town. The proposal met cordial support: and the institution has commenced operations. It is not intended as a lying-in charity; nor are cases of disease resulting from prostitution admissible.

We trust that those who have the management of the Leeds Hospital for women and children will take care that its benefits are confined to really deserving objects: and that while they refuse all females who, either from fault or from misfortune, have forfeited the title of "respectable", they will prevent the hospital from being made a refuge for the wives and children of comfortable tradesmen and well-paid servants.

* "When the old system" (of medicine) "shall have quite vanished from the earth, and the new one shall be established, then, for the first time, will the Gospel of the kingdom of grace be preached as Jesus ordered it to be preached, and received as God intended it to be received." (Extract from Mr. Everest's Sermon.)

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XXVII.

LONDON: FRIDAY EVENING, JULY 8, 1853.

NEW SERIES.

GENTLEMEN WISHING TO JOIN THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION ARE REQUESTED TO APPLY TO THE GENERAL SECRETARY, TO THE BRANCH SECRETARIES, OR TO THE EDITOR OF THE JOURNAL. The Annual Subscription is One Guinea. The Subscription runs from January to January; and members now joining will receive the Numbers of the JOURNAL from the commencement of the year. Members receive the JOURNAL free by post.

We have received at least fifty letters on the "Sunday question" within the last week. We propose to print some of them in next number.

TABLE-MOVING AND HOMŒOPATHY: VALUE OF EVIDENCE IN SCIENCE.

DR. FARADAY has written to the *Times* explaining his views on table-moving, and describing a very simple instrument, which shews that the motion is produced by a force exerted in the direction of the table moved, and that if no such action is exerted no motion follows. The inference is that it is produced by muscular action.

He concludes his letter by these very pertinent and thoughtful observations:

"I have been greatly startled by the revelation which this purely physical subject has made of the condition of the public mind. No doubt there are many persons who have formed a right judgment, or used a cautious reserve; for I know several such, and public communications have shown it to be so; but their number is almost as nothing to the great body who have believed and borne testimony, as I think, in the cause of error. I do not here refer to the distinction of those who agree with me, and those who differ. By the great body, I mean such as reject all consideration of the equality of cause and effect, who refer the results to electricity and magnetism, yet know nothing of the laws of these forces; or to attraction, yet show no phenomena of pure attractive power; or to the rotation of the earth, as if the earth revolved round the leg of a table; or to some unrecognised physical force, without inquiring whether the known forces are not sufficient; or who even refer them to diabolical or spiritual agency, rather than suspend their judgment, or acknowledge to themselves that they are not learned enough in these matters to decide on the nature of the action. I think the system of education that could leave the mental condition of the public body in the state in which this subject has found it, must have been greatly deficient in some very important principle."

These wise reflections are worthy of thoughtful perusal. We, however, as medical men, are not startled by this sudden display in a purely physical subject of the ignorance of the cultivated public to estimate the value of physical evidence, or of their conceit in pronouncing dogmatically on a question of forces whose laws they do not in the least understand. Faraday with philosophic coolness expresses no irritation at the deluge of pseudo-scientific impertinence with which he was overwhelmed; but M. Léon Faucault, the discoverer

of the rotation of the pendulum, in a recent article in one of the Paris journals, has given very full force to the feelings of irritability which were excited in a Frenchman of scientific repute, on appeals made to him on all sides by those who began by believing and wished him to confirm their views. Escape from Paris was his only remedy. We, however, are too familiar with these delusions: we have, unfortunately, too much experience in the same classes of deceptions to feel any great surprise or even much annoyance. When a large number of highly civilised people believe that infinitesimal doses of medicines, so small as to be incapable of detection by any tests, can produce a long catalogue of morbid sensations and actions in a healthy person, and can create a new disease, like, though stronger than the one to be cured—when multitudes believe this nonsense, which is not worthy of the consideration of any scientific mind for more than sufficient time to see its absurdity, and to dismiss it contemptuously out of his thoughts for ever—we can feel no surprise when we see the same inability to judge of the equality of cause and effect in this table-moving experiment.

And when we see the medical experience in the treatment of diseases of all past ages rejected for this new absurdity, we detect the same form of conceit which rejects a known cause, that of muscular action, for an unknown one, because it seems more wonderful and mysterious. In both cases the public will judge dogmatically and conceitedly of subjects which they do not in the least understand. That so coarse an experiment as table-moving, and one so open in all its stages to fallacies, should have been thought to be sufficient to prove the existence of a new force, only shews that the public are entirely unaware of the kind of evidence on which real discoveries in science rest; and with regard to the effect of medicines, the sources of fallacy are much greater, inasmuch as the interior of the human body is more complicated than a table with half a dozen hands upon it.

Those who are at all inclined to believe that truth in science is proved at all by the number of those who are convinced of it, may have a useful lesson now. The belief of a Faraday, a Thomas Bell, or a Grove, would be more weighty than the conviction of the myriads of drawing-room experimentizers who, "like Catafelto, with his hair on end, wonders at his own wonders". An affirmative in science cannot be made out of numerous negatives. No correct inference can be drawn from the largest amount of incorrect data: no law of nature can be discovered by any multitude of crude experiments.

In making these observations, we do not wish to be understood as thinking these table-turning experiments are valueless, and to be dismissed without consideration. They belong to the joint domain of physiology and physics, and deserve the investigation of severe science. What is wrong is the ignorance and conceit of those who would pronounce on matters of which they are incapable of judging, instead of reserving their judgment until they

are instructed by those few who are really capable of unravelling such scientific difficulties. And we cannot but agree with Faraday, especially as we have so much more evidence of the same fact, that a system of education, which leaves the public in such a state, must be deficient in some important principle—an observation which seems to apply even more forcibly to the United States than to civilized Europe.

CHARACTER IS PROFESSIONAL CAPITAL.

CHARACTER is to the medical man what cash and credit are to the merchant. The capital with which the medical man earns his bread, or makes his fortune, is his reputation; and when this is damaged in public estimation, the pecuniary loss which follows is certain, speedy, and severe. From the random and often groundless accusations which are constantly floating about in society against members of our profession, we cannot avoid believing that society is not sufficiently aware of the injury which they often inflict upon the most upright and the most skilful of our body, by listening to and repeating damaging statements, which, if investigated, turn out to have no foundation to rest on except groundless gossip. A professional man occupying a conspicuous position can, by integrity and blameless conduct, live down calumny, but with the private country practitioner this is impossible. Ruin, or a change of scene, are often the only alternatives of the unjustly calumniated provincial practitioner. Illustrations in abundance must occur to every one. To-day, our columns contain two cases more or less in point.

Mr. Fennell, a respected and successful practitioner at Wimbledon, in Surrey, in an evil hour, placed himself under the professional surveillance of a committee of ladies, and became medical officer to their Maternal Charity, upon terms of inadequate remuneration. Absurd stories of neglect were set afloat; and at last Mr. Fennell brought the clergyman of the parish into court, to account in damages for certain slanderous words alleged to have been spoken by his wife, who was one of the managers of the Maternal Charity. The jury considered that the ladies had a right to criticise and condemn Mr. Fennell, and that, from the position in which he had placed himself as their officer, their statements must be looked on as "privileged communications". At the same time, they exonerated Mr. Fennell from the charges imputed to him. This case is very painful to contemplate. We have on the one side a respected brother practitioner, and on the other a faithful parish clergyman, a man universally esteemed for his works of Christian philanthropy. Let us hope that the whole affair may soon be forgotten and mutually forgiven. As Lord Campbell said, there was no malice, and no quarrel in the case. The occurrence of this trial, however, teaches an important lesson to members of our profession, viz., that they ought not to place themselves in such a position as to entitle their professional practice to be made the subject of privileged debate by the ladies of the neighbourhood. It ought, likewise, to point out the necessity of letting the

public be well informed upon the great injury which may be done, through inadvertence, to the prospects of deserving medical men.

The history of Mr. Duncan's persecution and removal from his field of practice is well told, at p. 601, in Mr. Lloyd's letter. The ignominious and unanimous expulsion from the meeting of the representative of the unjust newspaper is a fact which strongly points out the advantages which medical men gain by enlisting under the union flag of our Association. The strong, decided, and unanimous step taken by the North Wales Branch in this matter forms a defence of Mr. Lloyd and Mr. Duncan; and, with the profession, it commands immediate and universal sympathy. Mr. Duncan may in the end be no loser; but in the meantime, by means of a foul conspiracy, he has been swindled out of his professional capital, and forced to recommence professional life in some other place. We trust that, wherever he goes, he may obtain public support and professional good will. His case is a very cruel one, and one which is, in all its aspects, as disgraceful to the *North Wales Chronicle* as it is honourable to the North Wales Branch of our Association. The motto on the front of the newspaper concludes with these words: "*We despise, abhor, and would control the liberty of the press, when that liberty degenerates into licentiousness.*" Does not the editor's conduct in the case before us clearly point out that *licentiousness* is in his vocabulary sometimes synonymous with *honesty*?

LAYING THE FOUNDATION STONE OF THE MEDICAL BENEVOLENT COLLEGE.

In a subsequent page will be found an account of the laying of the foundation stone of this institution by the Right Hon. the Earl Manvers, in the absence, from an attack of measles, of His Royal Highness Prince Albert. The commencement of building operations may well be a subject of gratification to Mr. Probert, the philanthropic projector, and to the friends generally of this great and national institution. We believe that the new contributions were at least £2000 upon this occasion.

PROGRESS OF MEDICAL REFORM.

MEDICAL Reform has been considered at all the recent Branch meetings in a way calculated to promote the cause. Better still, Lord Palmerston has intimated his intention of bringing in a bill during this session. Let us hope that he may meet with the hearty and enlightened support of the profession. We hope before next week to obtain a copy of the Bill.

THE VACCINATION BILL.

We give at p. 590 a copious abstract of the very valuable Report on Vaccination by the Epidemiological Society. It reflects the highest credit upon Dr. SMITH and his coadjutors. We may add, that it is a document which the public and the profession ought to be allowed to read, before any legislative measure be sanctioned by Parliament.

ORIGINAL COMMUNICATIONS.

OPERATION AND RESULTS OF QUARANTINE
IN BRITISH PORTS SINCE THE BEGINNING
OF THE PRESENT CENTURY.

By GAVIN MILROY, M.D.

(Read before the Epidemiological Society, June 6th, 1853.)

THE subject which I have the honour to bring this evening under your notice is one which seems to me to belong, in an especial manner, to a society whose declared aim is to investigate the natural history of epidemic diseases, with the view, of course, to the discovery of the most effectual means to control their development, arrest their spread, and mitigate their fatal malignity. Its importance will be recognised by all, when it is considered that quarantine professes to be a precautionary plan or process, whereby pestilences may be altogether kept at bay, and countries be thus preserved from the invasion of their destructive agency. No theme, therefore, in state medicine, more deserves our attention; and just in proportion to the importance of its bearings, is it necessary that our opinions be based upon reason and truth,—in other words, upon sound conclusions drawn from a sufficient number of well observed and faithfully recorded facts. Nor let it be forgotten that, independently of the immediate practical consequences involved in its right solution, this is one of the principal questions about which medical men are necessarily brought into direct contact and conference with the higher departments of public life; and on which the value of their advice is not confined within the circle of mere professional criticism, but will be subjected to the scrutiny of all who are interested in the freedom of international intercourse, from the statesman and the legislator down to the merchant and the traveller.

And yet, strange to say, there is not a topic in medical literature which has been so imperfectly handled, or on which there is less reliable evidence on the one hand, and a greater amount of extravagant and absurd assertion on the other. Unfortunately, too, there is not a single work in existence, as far as I know, to which any one seeking for detailed and trustworthy information upon the subject of quarantine can be referred. It is not so much as even named in the *Cyclopædia of Medicine*, published in 1835; while Dr. Copland, in his elaborate *Dictionary*, has, under the head of Protection from Pestilences, treated it with so little precision and clearness, and under the manifest influence of so strong a bias to particular one-sided views, that the reader finds himself both perplexed and unsatisfied. Nor has the subject fared better in the standard encyclopædias of general information. In the last edition of the *Encyclopædia Britannica*, published so recently as 1842, there is the most meagre mention possible—not exceeding a couple of dozen lines;—although the commercial bearings of quarantine are so important, that it has been estimated that a loss of little short of a million sterling is thereby annually inflicted on our shipping; and even this brief notice is not free from palpable error. Occasionally, at distant intervals, an article in a literary review has drawn public attention to the general question, or to some particular details; but never with the scope of a systematic or comprehensive inquiry.

You thus see how imperfectly the subject has hitherto been investigated; and you will probably all agree with me that it is high time, alike for the credit of our profession, which claims to guide public opinion upon such matters, as well as for the general interests of the community, that an attempt be made to ascertain the real state of our knowledge as derived from past experience, with the ulterior view of finding out, if possible, a clue to guide us to the truth through the meshwork of discordant and contradictory statements and opinions in which it is involved. This entanglement is necessarily not a little increased by the

circumstance, that it is not to one disease alone, but to several—and these varying too from each other in many features of character,—that the relations of quarantine have to be considered. Hitherto, it has been almost exclusively in reference to the oriental plague (against which quarantine was originally instituted) that the subject has been discussed. All the parliamentary evidence that has at any time been published in this country, is, as far as I know, limited to this one topic; and, indeed, so little have the bearings of quarantine to other diseases been generally thought of, that the writer in the *Encyclopædia Britannica*, a distinguished professor too of medical jurisprudence, does not so much as even name any other besides the plague. The plague, however, constitutes but one item in the inquiry; and even supposing that we had arrived at anything like decided conclusions respecting this form of pestilence, we should then have settled but a single point. How stands the question of quarantine with yellow fever?—with Asiatic cholera?—not to mention typhus fever, and the whole tribe of the exanthemata. Probably, most of my hearers are aware, that in very many places where quarantine restrictions exist, they are enforced, not against one only, but against each and all of the diseases now enumerated.

Upon this, however, as indeed upon every other head, the most ridiculous and contradictory practice is followed in different countries, and often too in different parts of the same country. Without descending to particulars, it cannot but be obvious that, to do anything like justice to the subject, a very wide and most varied field of examination is necessary; for, while each disease requires to be considered in reference to its own ascertained laws of propagation and diffusion, it is of the utmost importance to compare these laws together, to ascertain wherein they differ, and wherein they agree; with the view of determining how far the diseases are controllable by quarantine restrictions. The work is a large, and perhaps not a very easy one; but until it be fairly done, in a spirit of calm and conscientious inquiry, the medical profession fails, I think, to perform a duty which it owes to the public service. On the present occasion, I must impose upon myself much narrower limits, and shall confine my remarks to three only of the diseases alluded to; viz., the plague, yellow fever, and the Asiatic cholera. And here let me say, that it is not my intention to lead you into the troubled waters of controversy, respecting any single point in the purely medical history of these diseases. The object of this paper is not to discuss any theory, or to balance any dispute, but simply to narrate with thorough truthfulness facts and occurrences, as they have been recorded by trustworthy writers, leaving it to each gentleman to form such conclusions as the data may seem to warrant. Let me but offer one suggestion; viz., that in seeking to arrive at the truth in such an inquiry, we should,—while keeping our minds free from all preconceived opinions, and unperplexed by any other debateable questions save the one immediately under consideration,—apply the same laws of evidence, and follow the same mode of reasoning to discover the truth in respect of the origin of an epidemic disease, as we recognise to be necessary in the investigation of the causes of other natural phenomena, or in forming a judgment from circumstantial evidence in a case of criminal prosecution. Let facts and occurrences be looked at in their own light, and not through the coloured spectacles of a preadopted creed; let us avoid placing reliance on hearsay unsifted testimony,—let us be on our guard against eking out imperfect and unsatisfactory information by mere conjectures,—and let us cease to have recourse to that too common phrase, “it is highly probable”, in our endeavours to trace a connexion between antecedent and subsequent phenomena. It would be well, I have often thought, if the Scottish form of verdict, “not proven”, were more steadily before the minds and more frequently on the lips of medical juries, on a variety of occasions.

Quarantine is defined, very vaguely it must be acknowledged, in the *Encyclopædia Britannica*, to be “a trial which ships must undergo when suspected of pestilential infection”. If the trial alluded to were confined to the ships alone,

it would be a simple and comparatively a very inoffensive procedure. But this is a very minor part of the quarantine system. It is not the ship alone, but all and everything on board, animate and inanimate, that is subjected to the said trial; which trial consists in an enforced detention and seclusion for a period of from two or three to forty days (the word *quarantine* indicates the latter number), followed in many instances by the fumigation of persons and things, before they are set at liberty. Bear in mind too, that it is not necessary that any disease should actually exist on board at the time of the vessel's arrival, or even that any case whatever of illness should have occurred at any time during the voyage. It suffices, if she has come within a specified time from a place where disease is reported to be. This circumstance alone is generally regarded as an adequate reason for the imposition of quarantine restrictions, on the ground, either that disease may be present in an incubative form in the system of some person or another among the crew or passengers, or that its material cause—the *materies morbi*—may be adhering to some article or another on board.

Quarantine therefore is not (as is sometimes alleged by those who seek to make light of its grievances) the mere detention of the sick and infected, with the view of preventing their being landed at once and being taken wherever they or their friends may choose, without restraint or any regard to sanitary precautions. It applies equally to the well and healthy; nor is any distinction ever made between different individuals in point of susceptibility or liability to become attacked. All are treated alike; although, in the case of yellow fever, some may have had the disease and others have not; or, in the case of small-pox, some may have been vaccinated, while others are wholly unprotected. Quarantine bears to simple sanitary prophylaxis the same relation as a lazaret does to an ordinary clean and airy hospital.

The term is sometimes applied to the precautionary measure of isolating the sick on shore, or of establishing a cordon around a district, in the hope of confining a pestilence and arresting its progress. At other times, it is used to designate voluntary seclusion by individuals in health within their own dwellings, during the prevalence of sickness. But it would be much better if the word were confined to its original acceptation, viz., that of a detentive coast-guard against the importation of disease by shipping. It is in this restricted sense that it is employed in the following observations; my aim being to ascertain how far the system, as hitherto practised, has succeeded in the object for which it was established. Small islands present, of course, the most favourable opportunities for inquiry.

As to the various measures which have been adopted for the arrest of diseases, when they have found their way into a country, and as to the results of these measures, this topic does not come within the scope of the present paper.

I now proceed to my statement of facts; and, first, respecting the plague. As my narrative is purposely confined to the present century, I have no instance to mention until we come down to the memorable outbreak in Malta, in 1813. Two or three prefatory remarks, however, may not be misplaced. It is a fact worthy of notice that in Egypt, Syria, and Turkey—the countries which are always regarded as the parent lands of plague—there was a remarkable lull, all but a complete cessation, of epidemic plague between 1803-4 and 1812. We shall afterwards see that other epidemic diseases seem to have been similarly affected in remote countries during this interval. In 1812, one of the most formidable outbreaks of the pestilence that was ever known occurred in Constantinople; nearly 150,000 persons perished. Egypt also suffered rather severely in that year; and Smyrna on the west coast of Asia Minor, and Odessa on the Black Sea, not to mention other places, are also known to have been attacked. In the following year, 1813, the pestilence appears to have become more widely diffused; for we find that it prevailed more or less extensively in Wallachia, Roumelia, Albania, and Greece, all provinces

then of Turkey in Europe. There was also, at the same time, an unusual prevalence of malignant fever over the greater portion of Europe; and we shall afterwards see that, in this year, a fresh outbreak of yellow fever took place in different parts of Spain. At Malta, the spring season was remarked to be a very sickly one; sudden deaths were more frequent than usual; but the most noticeable feature of the prevailing medical constitution was, the remarkable tendency that existed to furuncular and other forms of unhealthy outward inflammation. "Every whitlow festered, and every scratch became an ugly sore. A tight shoe was sufficient to produce a livid boil with symptomatic bubo. The military hospitals were crowded with such cases."

I will now detail the ascertained facts connected with the development of the pestilence in the island, which it may be remarked, was believed to have been exempt from the plague for one hundred and twenty years. Nowhere perhaps is a quarantine establishment more complete in all its details and appliances than at Malta. The quarantine harbour is quite distinct and separate from the general harbour; there is an extensive lazaretto for the reception of the sick or suspected; and there is a regular staff of health officers. In consequence of the island being jealously watched by the Neapolitan and other Mediterranean States, which are ever ready to put her in quarantine upon the slightest pretext, the vigilance of all concerned is ever on the alert.

On the 28th of March, a vessel arrived from Alexandria, having a foul bill of health in consequence of the plague existing in that city. Two fatal cases of plague had occurred on board during the voyage. Her cargo consisted of flax. Immediately upon arrival, her crew were sent on shore to the lazaret, and the vessel was placed under the strict charge of health guardians, to prevent all communication either with the shore or with other vessels. The captain and one of the crew sickened in the lazaret on the 1st of April; both died on the 7th. In consequence of this, it was at first proposed that the vessel with her cargo should either be burnt, or taken out to sea and sunk; a mode of procedure that had been more than once resorted to at Malta for the public security.* A less summary plan to get her out of the way was however agreed to, viz., to send her back forthwith to Egypt, with her cargo untouched. Accordingly a fresh crew were put on board, and she was dispatched on the 10th of April. It is an interesting fact, that not a single case of sickness occurred, either on board during the ten days' voyage back to Alexandria, where she arrived in safety, or among the people engaged in unloading her in that port.

On the 16th of April, a young girl, the child of a shoemaker, living in one of the low unhealthy parts of Valetta, at a distance from the harbour, sickened with fever; she died in the course of a few days. The pestilential nature of her case was not suspected at the time. The mother was next attacked; in her case, the fever was accompanied with swelling of the inguinal glands. Suspicions now began to be excited, and rumours to be circulated, that the plague had made its appearance in the town. As it does not belong to the object of this paper to follow the subsequent course of the disorder, I shall say no more than that it is admitted by all who have written upon the subject, that, ere the Committee of Public Health had quite decided as to the real nature of the visitation, "the insidious disease was insinuating itself in every angle of the city, in places remote from the scene of its first appearance". The question for us to consider is, how did it find its way in, presuming

* The same decisive measure has been occasionally had recourse to on our own coasts. At the beginning of the present century, three vessels from Mogadore were sent round to the Nore, and there, by order of the government, upon the advice of the then quarantine authorities, sunk in deep water, along with their cargoes, consisting chiefly of goat-skins. The country had to pay upwards of £20,000 to the owners for this act of sanitary precaution! Something of the same sort was done at Stangate Creek in 1814. A cargo of skins, being deemed incapable of effectual expurgation from the possible retention of plague miasmata, without great risk to the men employed, was ordered to be sent on shore and burnt. In 1819, an infected vessel was submerged for a time in Malta harbour. No later than 1844, a work on Plague and Quarantine was published in London by a military medical officer. It had been in Corfu during the prevalence of the pestilence there; and it is gravely recommended that, "generally speaking, it will be best, perhaps the cheapest way in the end, to destroy the ship and cargo as soon as

that it was imported by the infected vessel, notwithstanding all the rigorous precautions which had been taken?—and, moreover, how came it to appear first, not among the health officers who had been put aboard of her, or even among the servants of the lazaretto where the captain and one of the crew had sickened and died, nor yet in the immediate neighbourhood of the *parlatorio* or landing-place, where the only communication between vessels in quarantine and the town is permitted, and that too through a grating, and under the eye of officers, but in a locality at a considerable distance, and among people wholly unconnected with the shipping? A rumour indeed got afloat, long after the event, that the father of the girl who was first attacked was in the habit of eking out his small gains as a shoemaker by acting as a smuggler, and that he had managed, somehow or other, to get a package of new linen from the vessel. It would occupy too much time to narrate the odd gossiping sort of evidence, on which this rumour was based. Suffice it to say, that it was never shown that the suspected package had ever been traced to the poor man at all (he died at an early period of the pestilence); nor indeed that any such package or anything else had ever been abstracted from the vessel. All that Sir A. B. Faulkner, the principal medical officer of the forces in Malta at the time, and who had made it his business to inquire into the circumstances upon the spot, ventured to say, was, that he thought "it an event not improbable that some of the family might have got goods from the vessel". The story was, however, believed by the quarantine authorities, and has been more than once repeated in print. It should, however, be known, that Dr. Calvert, physician of the forces, who was then in Malta, and who subsequently communicated a detailed account of the pestilence to the Medico-Chirurgical Society, regarded it as wholly groundless. "It is next to an impossibility", says he, "that it could have been brought in by clandestine intercourse. The crew of the infected ship was securely locked up in the lazaret; guards were placed upon the ship itself as long as it continued in the harbour; while every suspected person was seized and carried to the lazaret. But all was to no purpose: the disease seemed to laugh at their exertions, while it jumped from house to house, and from street to street. Those who had no communication together, as well as those who had, fell alike victims to its fury. Nothing could bring to light the way in which the infection was brought. Surely, if any evidence had been forthcoming, it would not have been kept back, when a free pardon was offered to the delinquents, besides a reward of a thousand scudis; or, if this was not sufficient, the dreadful anathemas that issued from the church could not have failed to produce confession."* The late Dr. Hennen, too, when medical inspector at Malta, after having examined with the utmost care all the official documents on the subject in the archives of the island, and collected the evidence of surviving residents who could give any information, came to the conclusion that the story about the smuggled linen was not to be credited; and Dr. John Davy, who subsequently occupied the same post, and whose attention was specially called to the results of the quarantine establishment, states, in his interesting work on Malta and the Ionian Islands, that the mode in which the pestilence was introduced "is still unexplained in a satisfactory manner".

I must now request you to accompany me to the little island of Gozo, distant about one mile from Malta. It had remained quite healthy throughout the dreadful visitation of the latter, in consequence, it was believed at the time, of all intercommunication having been subjected to the most vigilant and rigorous quarantine. Great, therefore, was the surprise, when a man died suddenly in Gozo, with suspicious symptoms, in the last week of February 1814. His daughter sickened a few days afterwards; she also died; and, within a few days, several inhabitants of the village where they resided were attacked. The following explanation of the mode in which the disease was thought to have

been introduced has been given. The man first attacked had shortly before come from Malta, bringing with him a box of new wearing apparel, which, it was alleged, he had concealed from the knowledge of the expurgators, by having buried it some months previously, when the plague existed in his neighbourhood. It had thus escaped proper purification. Sir T. Maitland, the Governor of Malta, in his official dispatch to the Colonial Minister on the subject, after recapitulating all the circumstances connected with the appearance of the disease in Gozo, expresses his opinion thus: "Although I should not be able to prove it in law, yet I have a perfect moral conviction that it was carried into the island of Gozo in the following manner"—viz., that as now described. Sir A. B. Faulkner appears to have had some doubts upon the subject, for he says: "Whether the above account of the box be strictly authentic or not, it is certain that the plague broke out immediately in the family after the arrival of their relative" from Malta. Dr. Calvert says: "A man indeed did go from this neighbourhood (near Casal Curmi) to Gozo, and was the first in that island who fell a sacrifice to the disease; but, as to his digging up a box, this was an idle report, and could not be substantiated, as I was confidently assured from the best authority."

Fortunately, the disease did not spread much, and soon ceased, after carrying off about sixty or seventy persons.

From Malta and Gozo, I now pass to the Ionian Islands, where the pestilence made its appearance at the end of the following year, 1815. Throughout the whole of that year, it had continued from the previous one in different parts of Albania, on the coast of Dalmatia, and along the shores of the Gulf of Lepanto. Ample warning had thus been given, that the dreaded foe was not far distant; and, indeed, Mr. Tully, one of the quarantine medical officers in Corfu, had been sent by the British government to Greece, with the view of gaining the most exact information. Moreover, the experience of the recent disastrous visitation of Malta had served to increase the vigilance of all the health authorities. As Mr. Tully has written a minute history of the disease in the Ionian Islands, we are enabled to follow it step by step. The place first attacked was the malarious district of Leftimo, in Corfu. Mr. Tully was at once dispatched thither, to organize measures for arresting the disease. But with these we have not at present to do. As to the origin or mode of introduction of the disease, this was then, and for a long time afterwards, quite inscrutable. The residents attributed it to the agency of an evil spirit; in other words, to endemic or indigenous causes; and Mr. Tully himself, in one passage of his work, states that he shared the opinion of those who believed that it was generated on the spot. It would seem, however, from the rest of his narrative, that, to use his own words, it "was ultimately ascertained, by the most undoubted proofs, to have been introduced through the medium of infected goods, which, by a strange combination, had remained on the island, under lock and key, for a considerable time." The goods alluded to consisted of a box, containing an opera hat, shirts, and a quantity of new silk handkerchiefs, with several copper kitchen utensils, which a smuggler was said to have left in Leftimo a year and a half before the appearance of the plague there, but was only opened shortly before the first cases occurred. Such is the alleged mode in which the disease managed to evade the quarantine at Corfu. It continued in the island until the May or June of 1816, when Cephalonia, another of the Ionian group, began to be infected. Mr. Tully was of opinion that it was introduced there by some men who had come from the Albanian coast, where the pestilence had now existed for eighteen months and upwards. They had been detained in quarantine for seven days, and had remained quite well all the time. But it was afterwards alleged that one of the party had brought with him some clothes, which he had stolen from two Turks, who had died. The story is, at best, a very lame one; nor was Mr. Tully himself quite satisfied about it. A more important fact is, that, while the plague existed in one part of the island, a most deadly form of endemic fever, with very similar symp-

* Trans. Med. Chir. Soc., vol. vi, p. 56.

toms, prevailed among the troops recently arrived from England, in another.

It does not appear that any other of the Ionian islands, save Corfu and Cephalonia, were visited by the pestilence. The immunity of Santa Maura is the more remarkable, as it lies between Cephalonia and that part of the Albanian coast whence the disease was supposed to have been derived.*

Since 1816, the plague has not appeared, as far as I am aware, in any of the British possessions in the Mediterranean, except a few imported isolated cases in the lazaret at Malta. To these I would now invite your attention for a few moments. Fortunately, the records of the quarantine establishment there, since the island came into the possession of Britain at the beginning of the present century, enable us to ascertain the truth. It appears that no vessel having plague on board arrived in Malta harbour, and that no case of the disease occurred in the lazaret, from that period down to 1813. Since the cessation of the pestilence in that year, to 1845, twelve vessels either actually infected or suspected have arrived, and about fifty cases of what has been regarded as plague—although in many of them the characteristic symptoms of the disease were absent, and they would have been recorded as cases of petechial typhus, had they not occurred in individuals from plague countries—have been treated in the lazaret. Now, it is an extremely interesting fact that of all the persons engaged in attending upon these sick, or who had been put on board the infected vessels as health guardians (and the number of these persons must have considerably exceeded a hundred) only four were attacked with any illness, and but one died. Two of the four men had been put on board a foul ship from Alexandria in 1821; they soon recovered. The other two cases occurred in men who had volunteered their services to be confined in the lazaret with a crowd of poor filthy Moors, on their way from Egypt to the Barbary coast.† It was one of these cases which proved fatal. The complete immunity of all the regular officers connected with the lazaret thus seems to show that there is little or nothing to be dreaded from the infection of plague, when patients are kept in clean, airy apartments. How different are the results, when the sick are compelled to remain in confined crowded places, as on board of a foul ship, for example! A vessel arrived at Zante, in June 1819, from Tunis, where the plague existed at the time of her sailing. There was no actual sickness on board when she arrived; but, as there was not a suitable lazaret ashore, she, with her crew of eight persons, was placed in strict quarantine in the harbour, having a health guardian on board to prevent all communication with the land. Within the next nine days, no fewer than seven of the crew, and the health officer, were attacked with a malignant fever, accompanied with bubos and carbuncles; every one of the cases terminated fatally. Only one of the unfortunate crew survived. Great credit was given at the time to the quarantine authorities that the fever did not spread to the shore.

I must not forget to mention that, among the many hundred men who have been employed during the present century in the lazarets of Malta and Marseilles (those of Genoa and other Italian ports may be added) in expurgating, as it is called, the bales of cotton and other articles of

merchandise in vessels from Egypt and Turkey, there is not a single instance of one of them having ever been attacked. This, with a host of other most interesting facts respecting the true history of plague, was first made known in the Parliamentary bluebook on Quarantine, in 1843, and in the admirable Report of the French Academy published in 1845. Before the appearance of these important documents, the utmost ignorance prevailed. The experience of the French and Italian physicians, and of our own countryman, my late lamented friend, Dr. Laidlaw, who witnessed the severe Egyptian epidemics of 1834 and 1837, has effected an entire revolution in medical opinion upon the subject, by proving the utter fallacy of the old idea, that it is chiefly, if not altogether, by direct contact with the sick or with *fomites*, i.e., articles imagined to be infected, that the plague is liable to be communicated, while atmospheric contamination has nothing to do with the matter. Upon this most absurd belief, the machinery of quarantine regulations has been mainly planned. We now know that the plague, in respect of the circumstances which affect or favour its development and spread, is altogether similar to typhus in our own country. The same measures of prevention and repression are therefore required in both instances. Since the appearance of the French Report, the relations of the plague to quarantine have excited much attention in this and in foreign countries. The publication of the first Report of the General Board of Health, in 1849, gave fresh impulse to inquiry. Our distinguished corresponding member, Professor Sigmund of Vienna, has for many years past done excellent service to the cause of enlightenment and truth by his numerous writings. Dr. Sigmund's authority is the more important, from his personal knowledge of the pestilence in the Danubian provinces at different periods from 1828 to 1837, and his thorough acquaintance with the state of almost all the lazarets on the continent. The results of his observations during his mission to Turkey and Egypt, on which he was lately sent by the Austrian government, are contained in his very valuable work on Quarantine Reform published at Vienna in 1850. It is much to be regretted that our own Government has not followed the example set by France, Austria, and Russia—that of sending competent medical men to those countries where the plague is endemic, or which have been most frequently the scene of its visitations, to collect reliable information upon its history, and to ascertain the actual results which have attended the quarantine and other precautionary measures hitherto resorted to in the cause of public health. Foreign countries charge us with saying much and doing little, except for our own immediate benefit and profit; and unhappily there seems to be too much ground for the charge. In a mere commercial view, no country is so deeply interested in the discovery of the truth and the right application of sound conclusions in practice, as our own.

Fitzroy Square, London, June 1853.

THE PROPRIETY AND MORALITY OF USING ANÆSTHETICS IN INSTRUMENTAL AND NATURAL PARTURITION.*

(IN A LETTER TO PROFESSOR MEIGS, OF PHILADELPHIA.)

By J. Y. SIMPSON, M.D., Professor of Midwifery in the University of Edinburgh, President of the Medico-Chirurgical and Obstetric Societies, etc., etc.

(Dated Edinburgh, 1st of August, 1848.)

MY DEAR SIR,—A few days ago, I happened to see your excellent epistle to me on the use of Anæsthesia in Midwifery, extracted, in an abridged form, from the *Philadelphia Medical Examiner* into the *London Medical Gazette*. It reminded me that, amid other avocations and work, I had hitherto indolently omitted to answer the objections

* A recent intelligent writer, who was detained for a week in quarantine at Santa Maura, upon landing from Albania, although that country was in perfect health at the time, describes the lazaret in which he was confined as the most miserable shed imaginable. "In short," says he, "during the whole range of my travels in Asia and Europe, I never met with the equal of this for the utter wretchedness of its accommodation and the insalubrity of the situation." The result of the sufferings he experienced during his detention was a severe attack of fever. (Spencer's *Travels in European Turkey*, etc., 1861.)

† This is but an instance of what is continually taking place in many of the lazarets in the East. It is surely a disgrace that such an enormity should exist in a British colony at all events, in the present day.

‡ The experience of the lazaret at Marseilles accords in a striking manner with that of Malta. No infected vessel had arrived there, and no case of plague had been seen in the lazaret from 1796 down to 1819. Between this year and 1840, only two infected vessels arrived; one in 1825, and the other in 1837. The entire number of cases received into and treated in the lazaret, does not appear to have exceeded four or five; and the only instance of sickness among the attendants and employees of the quarantine establishment occurred in a man who had been put on board an infected vessel as health guardian.

* The following letter to Dr. Meigs has been sent to us for publication by its author, Dr. Simpson. It was printed some time ago in *Philadelphia*; but has not yet been published in this country. ERRATA.

contained in your able and kind letter. And I feel that I am the more to blame for this neglect, on one account, namely, that as in your own country, so also in ours, there are few or no living obstetricians whose opinions and name carry, and deservedly carry, more weight with them than yours. Be so good, then, as bear with me now for a few minutes, while I endeavour to state in what respects I am inclined to demur to your arguments against anæsthetic midwifery.

On reperusing, as I have just done, your esteemed letter, it appears to me, that in it you ground your opposition to the adoption of anæsthesia in midwifery upon four or five different arguments, although you do not specialize them. I shall notice each of these arguments separately. You have not given them in any particular order. Let me begin first with the one which you have placed last.

1. *You object to anæsthesia in deliveries requiring "chi-surgical intervention", and especially in FORCEPS OPERATIONS, on the ground that the sensations of the patient afford us our best aid for the introduction of the instrument.*

In order to introduce the forceps with the greatest safety to the mother, you state that (to quote your own words) "the best guide of the accoucheur is the reply of the patient to his interrogatory, 'Does it hurt you?' The patient's reply, 'Yes', or 'No', are" (you observe) "worth a thousand dogmas and precepts. I cannot, therefore", you continue, "deem myself justified in casting away my safest and most trustworthy diagnosis, for the questionable equivalent of ten minutes' exemption from pain, which, even in this case, is a physiological pain."

In answer to this novel objection, you will excuse me when I say (for I say it most conscientiously), that I think every man who ventures to use the forceps, in any midwifery case, ought to know the anatomy of the parts implicated a thousandfold better than you here presuppose. You would have the accoucheur guide his instrument, not so much by his own anatomical knowledge, as by the feelings and sensations of his patient. In this, as in other points relative to any novel question in practice, we can often, it appears to me, best perceive the soundness or unsoundness of our views upon it, by considering and contrasting them with our established views on other analogous questions, regarding which the opinions of the profession have been long ago fixed and determined. Now, what would the surgical world, at this time of day, think of an operator who, in making a ligature of a large artery, such as the humeral, placed his chance of discriminating the attendant nerve from the blood-vessel which he wished to tie, by appealing, not to his own anatomical knowledge, but to the feelings of his patient, as he touched the suspected structures? "Does it hurt you?—Yes, or No?" Would our surgical brethren not denounce and decry the capabilities of any man who, in operating, required to have recourse to such imperfect and incompetent means for his anatomical direction and diagnosis? Would it be right and moral in a surgeon to deny to his patients the advantages of anæsthesia, in order that their sensations and sufferings should make up for his want of anatomical and operative knowledge?

But, in saying this, do not, I pray you, for one moment suppose that I fancy that the argument which you adduce betrays any want whatever of the highest degree of operative skill on your part. Nothing could be further from my thoughts. And, to confess the truth, I do sincerely believe that you yourself, while using the forceps, do not require to have recourse to any such rude rule as you here propound; and that, in fact, the rule itself, and the objection to anæsthesia in operative midwifery which it contains, is an *afterthought* on your part, which has only sprung up since the practice of anæsthesia was proposed. For, in looking over the excellent precepts which you have given relative to the use of the forceps, in the valuable work on midwifery which you published a few years ago, viz., the *Philadelphia Practice of Midwifery*, I find no trace or mention whatever of such a rule as you have

quoted above, in your letter to me. If that rule really formed, as you now state, the "safest and most trustworthy" guide in the operation, you would certainly have at least noticed it, or alluded to it in some way. In the precepts which you laid down in your work, you would assuredly not have forgot that one rule, which, you say, is worth a "thousand other dogmas and precepts". And further, it would, I think, have been only the more incumbent upon you to have mentioned it, seeing that all other authors omit the notice of it.

I feel assured that, when you come to reconsider dispassionately your opinions regarding the non-employment of anæsthesia in operative midwifery, you will alter these opinions; and when you come to employ anæsthesia in actual practice, in cases in which the forceps are used, you will find that, instead of impeding the application of instruments, the anæsthetic state *very greatly facilitates their use*. It enables you to guide the forceps far more safely to their destination, because it enables you, without any pain to the patient, to introduce your fingers for this purpose, far more deeply between the head and maternal structures, than you could do if the patient were awake, and in her usual sensitive state. You yourself state, in your published work on midwifery, that care should be "taken to direct the point (of the forceps) by the two fingers, as far as they can reach". (p. 300.) "If", you again observe, "any difficulty occurs in getting the second blade forward enough, the two left fingers that are guiding it will serve to guide it edgeways into the proper position." Now, the state of anæsthesia, I repeat, gives you, as I have oftentimes found, the power of fulfilling these and other most important rules, to an extent that never can be attained without it; and I am sure you will find them worth any "thousand dogmas and precepts" derivable from the mere sensations of the patient.

Besides, these sensations,—or rather the expression of them,—would constantly betray you, if you *did* place any dependence upon them. Under the same amount of pain, scarcely any two women would give you exactly the same expression of suffering. What one woman would loudly complain of, another would declare to be nought.

Before interfering instrumentally with the forceps, the labour has generally been allowed to endure for twenty or thirty long hours. After a poor patient has undergone such a protracted ordeal of pain and suffering, her mind in general is not, I fear, in a very fit state to guide the operator by her sensations or directions.

At page 302 of your published work on midwifery, you state that, when the forceps are used, the patient's mind is naturally wound up to a state of great anxiety. "It is strained", you observe, "to the highest tension, by the mere thought that she is under the operation." Now, putting entirely out of view for the moment the propriety of our saving our patients the increased corporeal suffering attendant upon instrumental delivery, is it not, let me ask, our right and our duty as medical men to save her, as we can do, from this trying state of mental anxiety at the time of operating? In most cases, she will have been suffering and struggling on for many hours previously. Why then thus needlessly and greatly intensify both her mental anxieties and physical sufferings at the time of our instrumental interference, when her strength, alike of mind and body, are perhaps little calculated to bear any increase of suffering; and, above all, when the resources of our art furnish us with simple and certain means of saving her from the unnecessary endurance alike of the one state and of the other?

But, in instrumental delivery, besides greatly facilitating the application of the forceps, and relieving the patient from enduring the pains of the operation, and that "highest tension" of mind which is present during it, the state of anæsthesia saves her, I believe, also, in a great measure, from the effects of the shock of the operation, and thus gives her a better chance of recovery. If we omit it, we omit, I believe, not only a means of saving her from the sufferings attendant upon the operation, but a means of

moving her from some of the dangers attendant upon it. When first publishing on the subject of *anæsthesia* in midwifery, in February 1847, I offered one or two observations on this point, which subsequent surgical statistics have amply fulfilled. In allusion to some cases of operative delivery, which I recorded, I observed: "The cases I have detailed sufficiently show its value and safety in cases of operative midwifery. And here, as in surgery, its utility is certainly not confined to the mere suspension and abrogation of conscious pain, great as, by itself, such a boon would doubtlessly be; but, in modifying and obliterating the state of conscious pain, the nervous shock otherwise liable to be produced by such pain—particularly whenever it is extreme, and intensely waited for and endured—is saved to the constitution, and thus an escape gained from many evil consequences that are apt to follow in its train."

The observations which I have hitherto made refer entirely to your opinion of *anæsthesia* in instrumental delivery. But,—

2. *You object to anæsthesia in NATURAL LABOURS, because you hold that the pain of natural labour should not be annulled, and that it is calculated to promote the safety of the mother.*

You regard, you say, "the pain of a natural labour as a state not by all possible means and always to be eschewed and obviated"—"a labour pain being"; you declare, "a most desirable, salutary, and conservative manifestation of life-force".

In the above expressions, you make no distinction between the two separate and distinct elements of which a so-called labour-pain consists, viz., 1, the contractions of the uterus; and 2, the sensations of pain resulting from these contractions. If you apply the language I have quoted to the first of these elements, the uterine contractions (and which contractions are *not* annulled by *anæsthetics*), I decidedly and entirely agree with you. If you apply it, however, to the sensations of pain produced by the uterine contractions, and which sensations are annulled by *anæsthetics*, I most decidedly and entirely dissent from your opinion.

In your treatise on midwifery, you make, correctly, the important distinction to which I refer. You state (p. 148), that "the word (labour) is highly expressive of the violent and painful struggles and efforts of the woman". You add, that "the essential element of labour is the contraction of the muscular fibres of the womb". And, at page 303, in speaking of the strength of these uterine contractions, you observe, "Let it be well borne in mind, that the expulsive powers of the womb are enormously great". In more than one place in your work, you allude to the intensity of the sensations of pain (the pangs and agonies of travail, as you term them, p. 155); and, at page 153, you speak of the "painful sensations" of the mother in the last part of labour as so great in degree "as to be absolutely indescribable, and comparable to no other pain". In your still later work on *Female Diseases*, speaking of these pains—the pains of parturition—you observe, "Men cannot suffer the same pains as women. What", you continue, "do you call the pains of parturition? There is no name for them but *Agony*." (*Females and their Diseases*, p. 49.)

The muscular contractions of the uterus form, you say, the first or "essential element" of labour. In that opinion, you and I are at one. And further, I quite agree that this cannot safely be "eschewed and obviated" in natural labour. Nor are they "eschewed and obviated" under the proper use of chloroform.

But the pain, the second element, is a non-essential element in the process. It is non-essential, because, 1, labour—that is, the uterine contractions—are occasionally, though very rarely, in the course of practice, seen to accomplish the full expulsion of the child with little or no pain; 2, in whole tribes of the human race, as in some of the black tribes, comparatively little or no pain seems to be endured, if we may believe various authorities; and 3, thousands of women have now been delivered with perfect safety, but

without any pain, while placed under the influence of *anæsthetic agents*.

I hold the pain to be *non-essential*, and I utterly protest against the truth of your opinion, that "the pain of a natural labour is a state not by all possible means to be eschewed and obviated". On the contrary, I maintain, that we omit and forego a mighty part of our professional duties whenever we forget the axiom of Bacon, that "it is the office of a physician not only to restore health, but to mitigate pain and dolours". And if, as medical men, we are called upon to mitigate and remove pain of any degree in our fellow-beings, we are surely called upon to mitigate and remove those "pangs and agonies of travail", as you term them, "which in degree are", in your own language, absolutely indescribable, and comparable to no other pain"—"pains for which there is no other name but *Agony*".

In your practice, do you not, let me ask, constantly use measures to mitigate and relieve the pains of headache, of colic, of sciatica, of pleurodynia, of gout, of rheumatism, and all the other innumerable "dolours" that flesh is heir to? Like other physicians, you deem it, I doubt not, your duty to wield the powers of your art in order to free those that submit themselves to your medical care from these and from other similar sufferings. But, if it is right for you to relieve and remove these pains, why is it not right for you also to relieve and remove the pains accompanying the act of parturition? I cannot see on what principle of philosophy, or morality, or humanity, a physician should consider it his duty to alleviate and abolish, when possible, the many minor pains to which his patients are subject, and yet should consider it improper and immoral to alleviate and abolish, when possible, pains of so aggravated a character, that, in your own language, they are "absolutely indescribable, and comparable to no other pains"—pains for which there is "no other name but *Agony*".

3. *You object to anæsthesia in natural labour, because you deem the pain of natural labour "a PHYSIOLOGICAL PAIN".*

"The sensation of pain in labour is", you observe, "a physiological relative of the power or force"; and "to be in natural labour is the culminating point of the female somatic forces".

Now, for the reasons that I have already stated, I entirely doubt if we should look upon the severe sensations of pain endured by our patients as truly "physiological", for, as I have just stated, they are *not* essential to the mechanism and completion of the process in the white races of mankind; and they are absent, to a great degree, in the black. The severity of them could, I think, be easily proved to be the result of civilization, and, as I believe, of that increased size of the infantile head which results from civilization. Parturition is always physiological in its *object*, but not in some of the phenomena and peculiarities which attend upon it in civilized life.

But, waiving this point, or the discussion of it, let me state, that even if I allowed all the intense pains of parturition to be "physiological pains", I cannot conceive that to be any adequate reason for us not relieving women from the endurance of them. Because nature has fashioned any particular physiological function in any particular manner, that, I opine, is no reason why the science and art of civilized life should not, when possible, alter and amend its workings. If it were improper for us, for instance, to intermeddle with the functions of the hair of the head, or of the skin generally, then all hats and other coverings for the scalp, all clothings and coverings for the body, should be at once abandoned and unconditionally condemned. If it were improper for us to alter and amend the functions of the eye, then all optical glasses, the telescope, the microscope, etc., must be thrown aside. And indeed not later than the seventeenth century it was held and argued so in England. For, in his *History* of the first beginning of the Royal Society of London, Sprat tells us that it was generally believed that this "new experimental philosophy (namely, the philosophical papers laid before the Society) was subversive of the Christian faith"; and many, he adds, mortally hated the new philosophy.

vented optical glasses, the telescope and the microscope, as *atheistical inventions*, which perverted our organs of sight, and made everything appear in a new and false light. (Disraeli). You argue as if we should not use means to eschew the pains of parturition *because* that pain is physiological. When Columbus first discovered your mighty American continent, a large portion of the inhabitants were unprovided with any kind of dress or covering. "To most of them," says Robertson, "nature had not even suggested any idea of impropriety in being altogether uncovered." (*History of America*.) And I do think that men living in such a state, could, against the fashion of dressing, use with far greater propriety and consistency than you or me, your own argument against anaesthetics in labour. Chloroform and ether should not be used in labour (you argue), because the pain against which they protect us is natural and physiological. No kinds of clothing or dress should be used (the original Americans might have equally argued), because the cold or heat against which they protect us are "natural" and "physiological".

I have a letter lying before me on the subject of anaesthetics in midwifery, by a very highly and very justly esteemed professor of midwifery in Dublin. It was penned in the end of last year (1847). "I do not," he writes, "believe that any one in Dublin has as yet used ether in midwifery; the feeling is very strong against its use in ordinary cases, and merely to avert the ordinary amount of pain which the Almighty has seen fit,—and most wisely we cannot doubt,—to allot to natural labour; and in this feeling I heartily and entirely concur."

The argument thus used, and so very well expressed by my Irish friend, is one which has been often adduced and repeated. Some minds at first gave immense weight and importance to it. For my own part I must confess that I never could view it as possessing any great force. Look at it as applied to any other practice which happens to be sufficiently old and established; and then we will see it in its true import. Supposing, for example, it referred to the *first* introduction of carriages into use; it would then read thus: "I do not believe that any one in Dublin has as yet used a carriage in locomotion; the feeling here is very strong against its use in ordinary progression, and merely to avert the ordinary amount of fatigue which the Almighty has seen fit,—and most wisely we cannot doubt,—to allot to natural walking; and in this feeling I heartily and entirely concur."

Nay, this frequently repeated argument against such innovations becomes not only, I think, ridiculous, but really almost irreverent, when we look far backward into the march of civilization, and apply it to any practices that are so very long established as to be very antiquated, and with which, therefore, the human mind has been long and intimately familiarized. Some one (but whom I cannot pretend to say) no doubt first introduced the practice of wearing hats, or bonnets, or a covering for the head. Supposing this practice, however, stoutly resisted, as doubtless it was at first, then the argument of my Dublin correspondent against this innovation would read somewhat as follows: "I do not believe that any one in Dublin has as yet used a hat to protect his head; the feeling here is very strong against its use in ordinary weather, and merely to avert the ordinary amount of wetting and cold which the Almighty has seen fit,—and most wisely we cannot doubt,—to allot to mankind: and in this feeling I heartily and entirely concur."

Some day a canal will, in all probability, be made through the Isthmus of Panama. It has, you are well aware, long been proposed to cut one; and there and thus unite the Atlantic and Pacific Oceans. When it was proposed in the sixteenth century, the clerical historian Acosta brought forward the following reasons against it. "I am," said he, writing in 1588, "of opinion that human power should not be allowed to cut through the strong and impenetrable bounds which God has put between the two oceans, of mountains and iron rocks, which can stand the fury of the raging seas. And, if it were possible, it would appear to me very just, that we should fear the vengeance of Heaven for attempting to improve that which the Creator in his

almighty will and providence has ordained from the creation of the world." The arguments which are here brought forward by the earnest Spanish priest against man meddling with and altering the impediments to navigation caused by the natural mechanism of the Isthmus of Panama, are essentially the same as those brought forward against men meddling with and altering the agonies caused by the natural mechanism of parturition in the civilized woman. We can all, perhaps, at this time of day, see through and smile at the character of the old priest's argument with regard to the supposed impropriety of changing and cancelling, if possible, the natural obstruction to naval commerce produced by a geographical isthmus. Some years after this, perhaps, our descendants will equally see through and smile at, the analogous modern argument in regard to the supposed impropriety of changing and cancelling, when possible, the physical suffering produced by a physiological function.

The truth is, all the tendencies of man in a civilized state of society, are to intermeddle with and change, and, as he conceives, improve the action of almost every function in the body. And each such improvement has at the time of its introduction, been, like the practice of anaesthesia, very duly denounced as improper, immoral, impious, etc., etc. I might refer to numerous such cases. Let me cite only one example. The human fingers are admirably constructed by our Creator for the function of seizing and lifting objects. The late Sir Charles Bell wrote a whole octavo volume—a *Bridgewater Treatise*—on the mechanism of the human hand as beautifully adapted for this and other functions. In the reign of the earlier Stuarts, forks were introduced from the continent to assist our hands in the act or function of seizing and lifting the divided portions of meat, etc., that we wished to eat. But this was a very sad and uncalled for innovation upon the old and established physiological functions of the human fingers; and, at the time, it was as loudly opposed and decried as the modern employment of anaesthetics in aiding the physiological function of human parturition. Disraeli tells us that the use of forks was so much reprobated in some quarters, that some zealous preachers denounced it "as an insult on Providence not to touch our meat with our fingers". Nature, they argued, has herself provided us with fingers of flesh and bone and nerve; and consequently it is unnatural and impious in man to attempt, in his human pride and arrogance, to substitute for these, artificial metallic fingers of silver and steel!

I repeat,—all our tendencies and workings in the present state of civilization, are attempts to intermeddle with and change and improve the action of almost every function in the economy. And assuredly if we use means in regard to the function of parturition with the view of ameliorating and abolishing the unnecessary, but, as you call them, "absolutely indescribable" pains that attend upon it, we would be doing nothing more than what you and I and all of us are every day and every hour doing in relation to most of the other natural or physiological functions of our own bodies.*

* "The principal 'moral' objection, as it has been termed, against the employment of anaesthesia in midwifery, amounts to the often repeated allegation, that it is 'unnatural'. 'Parturition,' it is avowed, is a 'natural function,' the pain attendant upon it is a 'physiological pain' (Dr. Meigs), and it is argued that it is improper 'to intermeddle with a natural function'; and to use anaesthetics is a piece of 'unnecessary interference with the providentially arranged process of healthy labour' (Dr. Ashwell). The above is, perhaps, the most general and approved of all the objections entertained and urged at this moment against the practice of anaesthesia in midwifery. But it certainly is a very untenable objection; for, if it were urged against any of our similar interferences with the other physiological functions of the body (every one of which is as 'providentially arranged' as the function of parturition), then the present state of society would require to be altogether changed and revolutionized. For the fact is, that almost all the habits and practices of civilized life are as 'unnatural,' and as direct interferences with our various 'providentially arranged' functions, as the exhibition of anaesthetics during labour. Progression upon our own two lower extremities is a 'providentially arranged' function, a 'natural process'; and yet we 'unnaturally' supplement and assist it by constantly riding on horseback and in carriages, etc. The 'physiological process' of walking is apt to produce pain and injury of the uncovered foot of man, and we 'unnaturally' use boots and shoes to bind the foot, and add to the protecting power of the cutaneous and other structures of the sole. Mastication and digestion are 'natural processes'; but we daily intermeddle with and attempt to aid them by the arts of cookery and dietetics; and so on with regard to other functions." (From *Report on Anaesthetic Midwifery*, by Dr. Simpson, in *Monthly Journal of Medical Science* for October 1846.)

Let me illustrate this last remark by one more example; for, as I have already said, it is only in this way that we can properly judge of the soundness or unsoundness of our views of novel points in theory or practice. You are well aware that the act of parturition has been often familiarly compared, as the late Professor Hamilton expressed it, "to the toils of a journey"; and like it divided into stages. "The sufferings of the mothers", says he, "have been in most languages compared to those of travellers." Now let us for a moment continue this natural simile between the function of parturition and the function of progression. You maintain that "labour is the culminating point of the female somatic forces". One of the most illustrious Presidents of your great American Republic—Thomas Jefferson—makes in his memoirs a remark of precisely the same import regarding walking or progression. He describes the act of walking, but not exactly in the same words, as the kind of "culminating point of the human somatic forces". "Walking", says the American President, "is the best possible exercise; habituate yourself to walk very far. The Europeans, he continues, value themselves on having subdued the horse to the uses of man; but I doubt whether we have not lost more than we have gained by the use of this animal. No one has occasioned so much (as the horse) the degeneracy of the human body. Our Indians go on foot nearly as far in a day for a long day as an enfeebled white does on his horse; and he (the Indian) will tire the best horses."—*Jefferson's Memoirs*, vol. i. p. 287.

Few, or none, perhaps, will question the abstract truth of Jefferson's observations on the above point. But, because walking or progression is a "physiological" function, and the practice of it is reputed salutary, would this be, with you, a proper and sufficient reason for never setting aside or superseding in any way this "physiological" state, in the same way as you insist, on the same grounds, that the physiological pain of labour should not be set aside or superseded. Because progression is a natural condition, would this be any adequate reason for your medical advisers adopting your own arguments against anaesthesia in midwifery, and insisting upon this, that, the next time you travelled from your own city of Philadelphia to the cities of Baltimore or New York, or elsewhere, you should walk the distance on foot, instead of travelling it by railway or any other artificial mode of conveyance? What opinion would you form of the judgment of any medical adviser to whom you entrusted your own health, if, on going next time to the New York or Baltimore railway station, he should gravely and solemnly repeat to you as his patient, what you tell your midwifery patients, and, in your own language, advise you to try to accomplish the intended journey on foot as, to quote your own words, "a desirable, salutary, and conservative manifestation of life-force"? And yet this would really be nothing more than making your *argumentum ad feminam* an *argumentum ad hominem*.

You state, in a passage which I have already quoted, that even the suffering accompanying instrumental delivery by the forceps is a "physiological pain". I do not, I confess, see why the suffering attending the use of the forceps, when the head is impeded by any cause of obstruction, should be regarded as a "physiological pain", any more than the suffering attending the use of the catheter in obstruction from the prostate gland or other morbid conditions of the urethra should be regarded as a "physiological pain". They are both operations intended to remove the natural contents of the respective viscera, when their operative removal becomes necessary.

But let us waive this point and return again to the analogy between the functions of progression and parturition. Suppose you plead with your medical advisers that, instead of insisting on your going on foot, they should allow you for once to take advantage of artificial assistance, and proceed on your journey from Philadelphia to Baltimore or New York by railway, because you were unable to walk the distance in consequence of being incapacitated by a rheumatic knee, or a sprained ankle, or an inflamed or blistered toe, and they replied to you that you should not care for this,

but still proceed and suffer, because the pain you might thus suffer was, to use again your own language, still only a "physiological pain",—would that argument, let me ask, be any adequate philosophic consolation under the endurance of your suffering? Or, would you not laugh at the logic of your medical adviser, and take your seat in the railway carriage in spite of his doctrine? And I have a strong fancy that betimes, in midwifery, patients will learn to adopt exactly the same line of logic and of practice under the analogous circumstances, and think and act too exactly in the same way.

4. You object to anaesthesia in labour, because the mother, in escaping by it from the "pangs and agonies of labour", may, in a few rare cases, be thus made to encounter danger to her own life.

"Should I", you observe, "exhibit the remedy for pain to a thousand patients in labour, merely to prevent the physiological pain, and for no other motive, and if I should; in consequence, destroy only one of them, I should feel disposed to clothe me in sackcloth and cast ashes on my head for the remainder of my days. What sufficient motive have I to risk the life or the death of one in a thousand in a questionable attempt to abrogate one of the general conditions of man?" Let me add that I have seen this argument of yours once or twice republished from your letter, and strongly insisted upon by the opponents of anaesthesia in this country.

And, indeed, in a new practice, such as that of anaesthesia, and with which the mind is yet not at all familiarized; the above forms one of that kind of apparently strong statements, which it is impossible to answer directly, or, indeed, by any other way than by taking, as I have already said, a corresponding illustration and simile from some other matter with which the mind is already familiarized. Let us for a moment longer, then, adhere to the familiar comparison which I have already taken up, under the last head, between the physiological function of human parturition, and the physiological function of human progression. Suppose, then, that you and I were standing at the Philadelphia station on the first day of the opening of the railway to Baltimore or New York. I wish the passengers to Baltimore or New York, or the shorter and intermediate stations, to proceed thither by railway; but you argue with them, like President Jefferson, that "progression is the culminating point of the human somatic forces," and that "walking is a desirable, salutary, and conservative manifestation of life-force," and that progression being a "physiological function," and fatigue a physiological pain, they ought to proceed on foot. I say, "No". Place yourself in a railway carriage, and thus eschew and obviate all the great fatigue and exhausting over-exertion of foot travelling. Then comes that answer and argument of yours which I have quoted, and which would run as follows:—"But should I exhibit, sir, the remedy for fatigue (a railway carriage) to a thousand travellers, merely to prevent the physiological exertion and fatigue of walking, and for no other motive, and if I should, in consequence, destroy only one of them, I should feel disposed to clothe me in sackcloth and cast ashes on my head for the remainder of my days. What sufficient motive have I to risk the death of one in a thousand in a questionable attempt to abrogate one of the general conditions of man, viz., his power of progression upon his own two lower extremities?"

I shall not stop to inquire whether among our supposed lady passengers or patients (uninjured, as most of them are, either to long pain or long walking) more than one in a thousand would not be worn out and destroyed by taking the journey on foot. A less proportion, I believe, would be found to be ultimately destroyed by the perils and dangers of the journey by railway than by the exertion and fatigue of the journey on foot; and the walk would shake and damage, both temporarily and permanently, many more constitutions than the railway carriage. I have a firm conviction that, on the great scale, there would be found a more absolute saving, both of human life and of human

health, by adopting the means invented by art than the means provided by nature. And I most firmly believe also, that a similar difference will yet be found to hold good between the two corresponding practices, of allowing women to pass through labour afflicted with all their usual physiological "pangs and agonies", and carrying them through that process without their being subjected to the endurance of these "pangs and agonies".

But I proceed to remark, that if your supposed theory with regard to the function of parturition were carried out in regard to the other functions of the human body, it would produce a vast and mighty revolution in the practices of civilized life. Follow it out, for instance, with regard to any one of them,—as, for example, with regard to the one we have already spoken of, viz., progression,—and see what would be the results. Ever and anon our newspapers contain paragraphs, telling us of one or more human lives being lost by collisions on railways, explosions of steamboats, upsettings of stage-coaches, etc. Consequently, according to your doctrine, that featherless biped and pedestrian animal, man, should no longer, when travelling, fly in railway cars, ply in steamboats, ride in coaches, etc., for these are evidently all so many questionable attempts to abrogate what you call "one of the general conditions of man", viz., his original pedestrianism.

In the great government and police of nature, disease and death are among the most certain "general conditions of man". If your theory were true, the practice of medicine itself should, I fear, be at once and summarily abandoned, for perhaps, in your own language, it is, at best, a questionable attempt to abrogate one of the general conditions of man—his tendency to disease and death; and I am sure you will agree with me, that in this "questionable attempt", human lives are often lost from the mistakes or the passiveness, or the want of knowledge and skill on the part of the physician. In England and Wales, in 1840, there were, according to the returns of the Registrar-General, above one hundred persons publicly and officially reported as having died from the effects of one drug alone, opium. But would this be any reason, or any ground of reason, for abandoning in medicine the use of opium—perhaps, in itself, the most valuable of all the remedies in our Pharmacopœia? Would this be any adequate argument for refusing to relieve, by a dose of opium, the next appropriate case of pain that you are called to? Or, because chloroform or ether, in a very rare case, now and again produces deleterious or even fatal consequences, should we refuse, in a thousand other persons, to mitigate and annul their agonies by its use?

In your esteemed letter to me, you quote some remarks from the celebrated old work, Raynald's *Birthe of Mankinde*, the first book on midwifery printed in English. Look at the prologue to the work. It is excellent in reference to the very matter we are discussing, viz., whether the rare accidents, from abuse or otherwise, to which any good gift may occasionally subject those who use it, should be a reason for repudiating the general use of that gift. "There is not anything," says Raynald, "so absolute and perfecte, but by the occasion of the abuse thereof at one time or other, may and doth ensue greate damage and danger to mankind." He instances fire and water, "two righte necessary elements to the use of man, without the which he could not live," yet sometimes "by fire hath bin consumed and devoured whole cities and countries; by water swallowed and drowned infinite men, shippes, yea and whole regions. Againe," he continues, "meate and drinke, to the moderate users thereof, doth minister and maintain life; and, contrary, to the unmeasurable and unsatiate gourmands and gluttons, it hath full many times brought surfeet, sicknesse, and at the last, death.... But," he argues, "should men for the avoyding of the aforesaid inconveniences, and for the reasons above said, condemne and banish fire and water, or forsake their meate and drinke? No, it were but madnesse once to thinke it."

Before passing from these, your supposed dangers from and objections to anæsthetics, let me add two remarks:—

First. I do believe that if improperly and incautiously given, and in some rare idiosyncrasies, ether and chloroform may prove injurious or even fatal, just as opium, calomel, antimony, and every other strong remedy and powerful drug will occasionally do. Drinking cold water itself will sometimes produce death. "It is well known," says Dr Taylor, in his excellent work on Medical Jurisprudence, "it is well known that there are many cases on record, in which cold water, swallowed in large quantity, and in an excited state of the system, has led to the destruction of life." (p. 8.) Should we, therefore, never allay our thirst with cold water? What would the disciples of Father Matthew say to this?

But secondly. You and others have very unnecessary and aggravated fears about the dangers of ether and chloroform; and in the course of experience you will find these fears to be, in a great measure, perfectly ideal and imaginary. But the same fears have, in the first instance, been conjured up against almost all other innovations in medicine, and even against innovations in the common luxuries of life. Revert again to our old simile regarding travelling. Cavendish, the Secretary to Cardinal Wolsey, tells us, in his life of that prelate, that when the Cardinal was banished from London to York by his master Henry VIII, many of the cardinal's servants refused to go such an enormous journey; for they were, says Cavendish, "loath to abandon their native country, their parents, wives, and children." The journey, which can now be accomplished in six hours, was considered then a perfect banishment. We travel now between London and Edinburgh (some four hundred miles) in twelve or fourteen hours. A century ago, the stage coach took twelve or fourteen days. And in his life of Lord Loughborough, Lord John Campbell tells us that when he (the biographer) first travelled from Edinburgh to London, in the mail-coach, the time was reduced to three nights and two days; but, he adds, this new and swift travelling from the Scotch to the English capital was wonderful; "and I was gravely advised," adds Lord John, "to stop a day at York, as several passengers who had gone through without stopping, had died of apoplexy from the rapidity of the motion." (*Lives of the Lord Chancellors*.)

Be assured, that many of the cases of apoplexy, etc., alleged to arise from anæsthetics, have as veritable an etiology as this apoplexy from rapid locomotion; and that a few years hence, they will stand in the same light in which we now look back upon the apoplexy averred to be caused by travelling ten miles an hour. And as to the supposed great moral and physical evils and injuries arising from the use of anæsthetics, they will by and by sound, I believe, much in the same way as the supposed great moral and physical evils and injuries arising from using hackney-coaches, were seriously described by Taylor, the water poet, two or three centuries ago, when these coaches were first introduced into London. In his diatribe against hackney-coaches, Taylor warned his fellow creatures to avoid them; otherwise, to quote his own words, "they would find their bodies tossed, tumbled, rumbled, and jumbled, without mercy." "The coach," says he, "is a close hypocrite; for it hath a cover for knavery; they (the passengers) are carried back to back in it like people surprised by pirates; and, moreover, it maketh men imitate sea-crabs in being drawn sideways," and altogether "it is a dangerous carriage for the commonwealth." Then he proceeds to call them "hell-carts", etc., and vents upon them a great deal of other abuse, very much of the same kind and character as that which has been lavished against anæsthetics in our own day.

In the course of your remarks, you imply, I think, though you nowhere explicitly state, another objection to anæsthetics in midwifery, viz.:—

5. *You object to anæsthesia in labour, because you do not consider that the mother encounters danger to her health or life from the endurance of the pains.*

"I have been accustomed," you observe, "to look upon the sensation of pain in labour as a physiological relative of the power or force; and, notwithstanding I have seen so

many women in the throes of labour, I have always regarded a labour-pain as a most desirable, salutary, and conservative manifestation of life-force."

If you hold, as your language appears to me to imply, that the sensation of pain, even when, as in labour, the degree of the pain is "absolutely indescribable", has no morbid or deleterious influence upon those who endure it, then I most decidedly disagree with you. On the contrary, I sincerely believe that the human constitution is so constituted that it cannot endure pain, particularly when that pain is long in duration, or severe in degree, without being more or less affected and injured by it. I know of many medical and obstetric authors, from the time of Ambrose Paré down to the time of Travers, Gooch, Alison, Burns, etc., who have stated and explained the common and hitherto unchallenged opinion of our profession in all ages, that pain was, *in itself*, deleterious and destructive, causing depression of the heart, syncope, and even, when in excess, sometimes producing speedy and sudden death. But, till the discovery in your own country of the possibility of annulling the pains of surgical operations by the inhalation of ether, I know of no writer in medicine, in surgery, or in midwifery, who held that pain, when "absolutely indescribable" in degree, was a matter of no importance in regard to the life or health of the sufferer, and should not be relieved even when we had the complete power of relieving it.

If the mere pain of the labour were, as you state, a "desirable, salutary, and conservative manifestation of life-force", its long continuance—the very length of it—would insure more certainly the health and safety of the patient, than its shortness. Anything "salutary and conservative" to the constitution, should manifestly be safe in proportion to the length, and dangerous in proportion to the shortness of its duration. But as far as regards the life and health of the mother, the pain of labour is perfectly the reverse of all this. It is safe in proportion to its shortness, and dangerous in proportion to its length. In the Dublin Hospital, (the tables of which afford the only data on this point that I know to refer to) when the women were six or eight hours in labour, thrice as many subsequently died as when their pain did not exceed two hours; of those that were from twelve to twenty-four hours in labour, five times as many subsequently died as of those that were from four to six hours ill: and so on in a regular progression. The longer this supposed "salutary and conservative manifestation of life-force", as you term it, endured, the greater became the mortality; so that, in the long run, the maternal mortality was *fiftyfold* greater among the women that were above thirty-six hours ill, than among those who were only two hours in labour; one in every six of the former dying in childbed, and one only out of every 320 of the latter.

Some time ago, I published a long series of statistics, tending to show, that out of a large collection of cases of the same operation (viz., amputation of the limbs), performed with and without anæsthesia, those who were operated on under anæsthesia (and consequently without the usual suffering), recovered in a much larger proportion, than those who had the same operation performed without anæsthesia, and whose constitutions were subjected to the endurance of the usual pains and agonies of the surgeon's knife.

The same result holds good, I believe, in midwifery as in surgery. Save the maternal constitution, either by natural or artificial anæsthesia, from the endurance of the pains connected with parturition, and you will enhance both the chances of her recovery and the facility of it. Among your red Indian and other uncivilized tribes, the parturient female does not suffer the same amount of pain during labour, as the female of the white race; and in consequence of this escape, they recover far more rapidly from the effects of parturition. Nor are fatalities at all common among them. So easy is the convalescence among uncivilized tribes, that Strabo, Marco Polo, and other historians and travellers, tell us of whole communities in which the husband

immediately went to bed for a number of days, upon the birth of a child, and the wife watched and nursed him. "They that write the history of America," says Guillemeau, "tell of the women in that country, that, as soon as they be delivered, they presently rise up and lay their husbands in their room, who are used and attended like women in child-bed." (*Childbirth: or the Happy Delivery of Women*).

Among the patients who have been delivered in Scotland, under anæsthesia, the rapidity of the stage of convalescence has, as a general rule, been increased in a degree that seems often to have surprised the patient herself, as much as her escape from the labour pains themselves. Many of my obstetric brethren have remarked this circumstance to me. In fact, on awaking after delivery, the patient does not encounter and endure the usual feelings of exhaustion and fatigue. Some have declared to me, that they have felt as if they had awoke from a refreshing sleep. And when we consider the capabilities for the endurance of suffering and exertion, among the class of patients in civilized life upon whom you and I attend, perhaps the propriety for employing anæsthesia during labour may appear still more evident. Unaccustomed by their mode of life to much pain and fatigue, patients in the higher ranks of life are not fitted to endure either of them with the same power or the same impunity as the uncivilized mother, or even as females in the lower and hardier grades of civilized society; and hence is there not the greater propriety and necessity in the physician employing all the means of his art, so as to save them, as far as possible, from their sufferings? To illustrate the point, let us revert again to our old comparison between the physiological functions of progression and parturition. Let us compare for a moment our ideas of the effects of fatigue from walking, and of pain from parturition, upon the female constitution: and surely the comparison is not an unfair one for your views, as far as the severity of the effects of the two influences, physical fatigue and physical pain, are concerned; for surely the effects of pain, of "absolutely indescribable pain", should be greater upon the constitution than mere muscular fatigue. Suppose then that our patients, at the end of the ninth month of pregnancy, had to walk on foot a continuous journey of one, two, three, six, or a dozen or more hours' duration, that is, of five, ten, twenty, or thirty miles, or upwards, *instead* of passing through a continuous journey of recurring labour pains of the same duration, the pains gradually becoming stronger, and latterly becoming "absolutely indescribable, and comparable with no other pains"—what would be the result, with, say one hundred ladies of the upper classes of society? Some of them might be little or not at all affected by the journey; others, weak perhaps when they began, would suffer more or less severely from it. Not a few would be inclined sooner or later to stop, and beseech you, if you were the medical attendant upon them, to save them from further exertion and fatigue, by allowing them to be carried or coached the required distance. In answer to their solicitations, would you console them by telling them that, after all, progression was a "conservative manifestation" of life-force, and free from danger; or would you take the other view, and allow them the means of travelling the required distance by carriage or rail? I am sure you would have recourse not to the former but to the latter, for you would fear and dread the effects of fatigue upon the fragile constitutions of your lady patients. And I repeat, that certainly the effects of the endurance of pain are as great, if not greater, upon the constitution, than the effects of the endurance of fatigue. But if you would allow your patients to ride the supposed journey, instead of unnecessarily forcing and compelling them to walk it on foot, equally, I think, should you allow them to escape what you term the "pangs and agonies of travail", by saving them by chloroform, or other anæsthetic agents, during their travail, from all the unnecessary endurance of these pangs and agonies.

You state "I have not yielded to several solicitations as to the exhibition (of anæsthetics) addressed to me by my patients in labour." If, when driving out into the country, you perchance meet one of your fair patients, a husband

from Philadelphia, walking homeward, but so tired and way-worn that every five or ten minutes she stopped and groaned for fatigue, "absolutely indescribable and comparable to no other fatigue", I am sure you would consider yourself bound, on the principles of mere common humanity alone, not to withstand her "solicitations" to be driven home in your carriage, and thus relieved of her present anxieties and suffering (not to speak of the future morbid effects of these). And I cannot see why, if you do this (and who would not do it?) to relieve a patient from the mere effects of fatigue, you could refuse to relieve the same lady when in "the pangs and agonies of travail", from the endurance of pains which are, in your own words, absolutely "indescribable and comparable to no other pains".

"Perhaps," you observe, "I am cruel in taking so dispassionate a view of the subject." Of course it would ill become me to pass any such judgment upon you. But I feel this, that you and I, and other teachers of midwifery, are placed, in reference to this question, in a position far more fearfully responsible than ordinary medical practitioners. The ordinary obstetric practitioner has little or no power, except over the relief or the perpetuation (according as he may choose it) of the sufferings of his own immediate patients. But you and I, as obstetrical teachers, may, through our pupils, have the power of relieving or of continuing the sufferings of whole communities. If, perchance, you persist for some years longer in your present opinion, it will have the effect of inflicting a large amount of what I conscientiously believe and know to be altogether unnecessary agony and suffering upon thousands of our fellow-beings. If you review and alter your opinions, which I earnestly hope you will do, and make yourself sufficiently acquainted with the peculiarities in the mode of action and mode of exhibition of chloroform during labour, a vast proportion of human suffering may, even within the next few years, be saved by your happy instrumentality and influence.

Feeling as I do deeply the great responsibility in this respect of your situation and of mine, I trust you will kindly pardon and excuse me, if anywhere in the preceding remarks I may have appeared to defend my views with too much earnestness. If I had to rewrite or revise the observations, I would perhaps have stated them more accurately; but I must send them as they are; and along with them I beg to send also the most sincere esteem and reiterated respects of,

My dear Sir, yours very faithfully,

J. Y. SIMPSON.

To Dr. MEIGS,
Professor of Midwifery, Philadelphia.

CASE OF CONGENITAL DIAPHRAGMATIC HERNIA.

By JAMES CRANG, Esq.

On February 5th, I was hastily summoned to attend Mrs. K., in her confinement. On my arrival, I was informed that she had been in labour seven hours. On an examination, I found the membranes ruptured, and the head of the foetus presenting. The labour progressed favourably, and she was delivered of a well formed female infant; which showed very faint symptoms of life. The pulsation of the funis having ceased; I instantly divided it, and used every possible effort to save the child. No action of the heart could be discovered on the left side; but on grasping the chest, I felt, as I then believed, a slight pulsation in my thumb. I then placed two fingers on the same spot, and felt two distinct beats of the heart on the right side; after which it ceased. I felt great anxiety to open the body, and earnestly requested the parents to allow this to be done. They readily consented.

EXAMINATION OF THE BODY. On February 7th, my son accompanied me; and on separating the sternum from the ribs, and turning it back, we discovered the heart and both lobes of the lungs folded together on the right side,

and resting on a portion of the ileum, the other portion of which, with the stomach, large intestines, etc., filled the thorax. The diaphragm was perfect, with the exception of a small round aperture, which admitted a straight part of the colon to descend to the rectum. The liver, covering the kidneys, filled the abdominal cavity. The contents of the pelvis were perfect and well defined.

a. Stomach.

b. Heart.

c. Intestines within cavity of thorax, pushing the lungs upwards and to the right side.

d. Left lobe of liver turned up. The rough edge of the diaphragm is seen above it.

e. Portion of intestine within abdomen. The bladder is conspicuously seen in its usual situation.

Dr. J. G. Swayne, of Clifton, has kindly furnished me with a drawing of this case; and I intend exhibiting it at our anniversary Meeting at Swansea. The preparation is deposited in the Museum of the Bristol Medical School.

Timsbury, Somerset, July 1853.

CLINICAL NOTES ON CASES IN THE ROYAL SOUTH HANTS INFIRMARY.

By JOSEPH BULLAR, M.D., Physician to the Royal South Hants Infirmary.

INFLAMMATION OF THE SCIATIC PLEXUS.

DR. ROMBERG, in his valuable and very complete treatise on *Diseases of the Nervous System*, translated by Dr. Sieveking, and published by the Sydenham Society, remarks that we are too apt to look on sciatica as the sole representative of neuralgia of the inferior extremities: whereas there are no branches of the lumbar or sacral plexus which may not be affected; though, by the absence of an accurate diagnosis, founded on a knowledge of the course of the nerves, we are apt to look at them in the gross, and often also to disguise them under the conventional terms of lumbago, rheumatic pains, etc. The following case is to the point. It would have been called sciatica if seen early, or paralysis of the bladder, had its early history not been known; though, by comparing the history and symptoms with the anatomical distribution of the nerves affected, it was evidently an instance of inflammation at first affecting the external branches of the sacral plexus, which form the lesser sciatic, passing subsequently into paralysis; and as the numbness was attended by paralysis of the bladder and rectum, and as these parts are supplied by the internal nerves of the sacral plexus, it is a fair inference that these were also involved. The pain was not severe below the ham, but there was tenderness on pressure between the tuber ischii and the great trochanter, so that the greater sciatic was probably somewhat involved, though not severely.

CASE. Mary N., aged 35, unmarried, a tall and large woman, had been ill four weeks before admission into the Royal South Hants Infirmary. She first suffered from severe pain in her back, and this was followed by a sudden sensation of numbness and loss of power of the upper part of the left thigh, immediately succeeded by very severe pain occupying the external surface of the thigh, and reaching to the popliteal space. It was so intense that she often fainted, got no sleep, and was unable for five nights before admission to lie in bed, as the pain was then aggravated. No active means appear to have been adopted.

On admission (Jan. 25th, 1853) she referred the pain to the left buttock and upper part of the thigh; it extended downwards on the outside of the thigh as far as the popliteal space. The parts were tender on pressure. She was cupped between the trochanter major and tuber ischii, and two grains of calomel and one grain of opium were given every four hours, with great relief to the pain, so that after the cupping she was able to sleep. On January 28th the cupping was repeated over the sacrum, which was the most tender spot, and the pills were continued three times a-day. The pain quite abated; and on the 2nd of February she complained that numbness had replaced the pain, and she was unable to pass urine, so that the catheter was used night and morning. The bowels became so torpid as not to be opened except by drastic purgatives. The calomel and opium were discontinued, as the mouth was slightly affected. With the paralysis of the bladder, the urine gradually became phosphatic. Nearly half the vessel was filled with ropy mucus, which, under the microscope, shewed an abundance of the usual prismatic crystals of the triple phosphate; and this, after some days, was replaced by abundant purulent matter coloured with blood. As this continued to increase, the bladder was injected night and morning with one drachm of diluted nitric acid to a pint of water, and an ounce and a half of the infusion of the *diosma crenata* was given three times a-day. Under these means, the bloody pus diminished in quantity and ceased to be secreted, and the urine gradually regained its healthy, acid state, but the bladder remained paralytic, and the bowels were never opened, except by strong aperients, and then the motions were usually passed in bed. On the 4th

March, one grain of strychnine was added to each pint of infusion of buchu; and on the 9th, in addition, five

grains of the pilula ferri comp. were ordered twice a-day; on the 10th, sixteen minims of the tinct. ferri hydrochl. three times a-day were substituted for the pills. Under the steady use of these chalybeates, the power of the bladder slowly returned; and on the 7th of April she was discharged. The bladder, however, had become more irritable than natural, and she still complained of numbness over the left buttock and outer surface of the thigh, and some weakness of the limb. In other respects she was well. Two months afterwards, although she did not make water more frequently than usual, yet occasionally she would pass it suddenly and involuntarily; and she still complained of the numbness and want of the usual strength of her left leg. Her health was good.

REMARKS. Judging from the seat of pain in the first instance, and from the numbness of the integuments, and the paralysis of the bladder and rectum subsequently, this case was one of inflammation chiefly affecting the internal branches of the sacral plexus which supply the rectum, bladder, and uterus, and of those external branches which form the lesser sciatic. The inflammation, which was severe and acute, was followed with loss of nervous power, indicated by paralysis of the bladder and rectum, and numbness over the gluteal surface, groin, and external surface of the left thigh. Cupping, with calomel and opium, relieved the inflammatory condition of the nerves, speedily subduing the pain, and after the inflammatory symptoms had subsided, the paralytic condition of the bladder gradually yielded to full doses of iron and strychnine. The value of injections containing diluted nitric acid, as recommended by Sir B. Brodie, was very marked in stopping the profuse secretion of purulent matter mixed with blood from the mucous membrane of the paralysed bladder. Until these injections were used, this secretion increased rapidly, commencing with that ropy mucus which is said to be the effect of phosphatic urine or pus-globules, and then becoming like pus mixed with a very considerable quantity of blood, and daily increasing in quantity. The effect of the injection was decided; the secretion diminishing, losing its bloody appearance, and soon ceasing. The infusion of buchu, which was given at the same time, was also of service in restoring the urine to a healthy state. As might have been expected from the severity and long continuance unchecked of the inflammation of the nerve, and the great disturbance of the bladder, the latter remained irritable after the paralysis had been removed, and the integuments supplied by the lesser sciatic nerve continued to be less sensitive than natural.

Southampton, July 1, 1853.

BIBLIOGRAPHICAL NOTICES.

REPORT ON SMALL-POX AND VACCINATION, presented to the President and Council of the Epidemiological Society, by the Small-Pox and Vaccination Committee, the 26th day of March, 1853. Printed by order of the House of Commons.*

This Report commences with a statement of the circumstances under which it was produced, Lord Lyttelton having introduced into the House of Lords a Bill for the extension of Vaccination; and the Committee considering it desirable that he and the Government should be put at once in possession of the facts collected by them. It consists of the statistics of small-pox and vaccination in Great Britain and Ireland, and in various European countries from which information had been received. It also contains an account of the laws and regulations connected with vaccination, adopted in different countries.

This information was obtained from the most authentic sources: in *England*, from the Registrar General, the Poor-law Board, the Board of Health, the public vaccination

* This Report is to be obtained at HANNAH'S, New Turnstile, or at Street, Westminster. Price 6d. It is named on the back "Lancet, Seaton", etc.

and from many hundreds of private medical practitioners throughout the country; *abroad*, from the government of each country, through its ambassador or representative at the Court of Her Majesty. The information thus received has been very full and satisfactory on several points:—

I. THE EVILS OF UNCHECKED SMALL-POX, although too well understood to require demonstration, have been presented before the Committee in a definite and authentic form.

II. THE SAFETY AND EFFICIENCY OF VACCINATION, AS A PROPHYLACTIC AGAINST SMALL-POX, appear to have been satisfactorily established, not only as the concurrent and unanimous opinion of nearly two thousand medical men who have corresponded with the Committee, but also on the following grounds:—

1. The general immunity from small-pox, with which it is found that those who have been vaccinated can mingle with small-pox patients. This fact requires no proof, being fully admitted on all hands.

2. The gradual decrease in the mortality from small-pox, as compared with the general mortality, since the introduction of vaccination. This is illustrated by tables, showing the average mortality from small-pox within the bills of mortality every decennial period, during the half century preceding vaccination, as compared with the mortality during the last half-century. A century ago, the rate was about 100 deaths from small-pox to every thousand deaths from all diseases: the present rate is 16 deaths from small-pox to every thousand. A similar result appears in the various European countries, in which the average deaths from small-pox have been reduced by vaccination from 66·5 to 7·26 per 1,000.

3. The virulose mortality is lowest in those countries in which, by compulsory laws or otherwise, vaccination is most efficiently carried out. "On this point", say the Committee, "we have obtained the most important and authentic information."

"But we would first desire to give a summary of the laws respecting vaccination in some of the principal European states. Those from which we have already received replies to our inquiries addressed to them on this head, are France, Belgium, Sardinia, Prussia, Lubeck, Hanover, Frankfort, Bavaria, the Grand Duchy of Oldenburg, Hamburg, Austria, and Sweden. From the following countries we have not yet received information: Holland, Naples, States of the Church, Parma, Tuscany, Spain, Portugal, Russia, and Turkey.

"With regard to the kingdoms contained in the first category, we may state that, in most of them, with or without the aid of laws rendering the omission of vaccination penal, the performance of that operation is made essential to the enjoyment of so many municipal and other advantages, that the general diffusion of it is pretty certainly attached. In Austria, Bavaria, France, Prussia, Sardinia, Lubeck, Frankfort, and Hamburg, the production of a certificate of successful vaccination is an indispensable preliminary to admission to public schools, and in many instances to private schools. In Austria, Frankfort, Sardinia, Belgium, and Lubeck, no relief is given from public funds in case of poverty; there is no admission to almshouses or orphan asylums, without a similar certificate. In Frankfort, proof of vaccination is an indispensable condition of citizenship; nor is any person allowed to take a servant or apprentice who has not been properly vaccinated. The same rule, so far as apprenticeship is concerned, applies to Bavaria; in which country, as well as in Prussia, even the rite of matrimony is withheld until the proper certificates or other evidence of vaccination have been produced.

"In the kingdoms last named (Prussia and Bavaria), direct compulsion by fine is employed in addition to these means; the fine in Bavaria augmenting annually until the law is complied with. In Austria there is no fine; but if it be known to the police that a person is unvaccinated, they have authority to take him forthwith and see that the operation is performed.

"Two countries only, of those from which we have received information, appear to rely wholly on the system of fine, and do not employ any of those indirect measures which we have enumerated. In Hanover, the punishment is fine or imprisonment. In Sweden, a person who refuses to comply is taken before the magistrate and reprimanded in the first instance; he is after-

wards fined, if he continues to disobey; and the fine is increased until obedience is obtained. It is right, however, to state, that in both these countries, as well as in Austria, Bavaria, and the Grand Duchy of Oldenburg, great facilities for vaccination are afforded to the population by the appointment of district vaccinators (paid generally by the state), whose duty it is to vaccinate at appointed times and at convenient stations, or even from house to house.

"In France and Belgium, rewards (prizes, and gold and silver medals) are given to those vaccinators who have distinguished themselves by zeal in the discharge of their functions.

"In Great Britain and the United States of America, vaccination (except for those who enter the military and naval services, and the like) is entirely voluntary; nor are any inducements held out to medical men to encourage them to exertion."

The results of these opposite modes of proceeding are illustrated in two tables, one of which shows the mortality in various places in England, Scotland, and Ireland, from small-pox, as compared with the total mortality, for ten years, ending 1840 or 1851; the other shows the mortality from small-pox in various countries in which vaccination is directly or indirectly compelled, as compared with the total mortality for various periods stated in the "tables exhibiting the mortality from small-pox in various countries," at the end of this Report. The Report then proceeds as follows:—

"On looking at these tables, we cannot fail to be struck with the fact, that the proportionate mortality from small-pox in England and Wales is considerably more than double what it is in any country in which vaccination is compulsory. So likewise, as will be seen by reference to the tables printed at the end of this Report, the proportion of deaths from small-pox in London to the total mortality is three times, and in Glasgow as much as six times, what it is in Brussels, Berlin, or Copenhagen.

"We are here desirous of stating to the Council our opinion, that the results exhibited in the second of the tables given above, favourable as they are to vaccination, would be still more so, if, in the countries comprised in it, proper regulations existed with regard to the age at which the operation should be performed. In some of those in which direct compulsion is employed, the public vaccinations being annual, it necessarily happens that a large number of the children are many months, a year, or more than a year, old, before the opportunity is afforded them of becoming protected; while in those states in which the compulsion is only indirect (as by requiring certificate of vaccination for school attendance, etc.), it is clear that the operation may be much longer deferred. The consideration is a very important one, for a large proportion of the mortality from small-pox occurs under the age of one year. We shall have to show, by-and-by, that, in England and Wales, this proportion is as high as 25 per cent.; and, though we have not facts for determining what is the percentage in the various continental states, we may infer from the returns which we have from Paris (where it is found to be upwards of 14 per cent.), that this must be very considerable.

"It is possible that to some difference in custom with regard to the age at which vaccination is performed, may be due a portion of the discrepancy found to exist in the amount of mortality in the countries comprised in the second table, varying as it does from eight per 1,000 in Saxony to two per 1,000 in Lombardy. Much also will be due to the nature of the provisions of the various enactments, but probably still more to the zeal and energy with which these are enforced; for, even in those countries in which the laws are most stringent, it is not to be denied that they may be and sometimes are evaded. If good laws could be so worked as to secure universal vaccination, there is little doubt that the mortality from small-pox might be reduced everywhere, even below what it is in Lombardy, if, indeed, it might not be wholly got rid of. In the kingdom of Hanover, in the year 1847, out of a total mortality of 45,850, there were but eight deaths from small-pox, or one in 5,728; and

* "How much depends on this will be seen by referring to some tables inserted in the Appendix (A.), in which are given the vaccinations for ten years (from 1841 to 1850) in the whole kingdom of Belgium and in the province of Luxembourg. From these, it appears that while the vaccinations in the entire kingdom were to the births as seven to twelve only, in Luxembourg they were as ten to eleven. The law in this province being, of course, the same as for the rest of the kingdom, the excellent state of vaccination must be mainly due to administrative zeal and activity."

we find it stated on the highest medical authority, that in Denmark 'variola had at one time disappeared before the defensive influence of compelled vaccination'; though it is added, that 'chance, and a careless security engendered by the absence of the pest, have led to its re-introduction there.'

"The consideration we have just suggested is of the utmost importance, and well worthy of the best attention of our legislators; for we are firmly convinced that no law will be efficacious unless it holds out inducements to stimulate the zeal and energy of those employed to put it in action; while at the same time it is worked with a machinery and in a mode in accordance with the feelings of the people. In the course of our inquiries, we have had ample opportunities of seeing the value of administrative exertions, both with regard to the working of the Vaccination Act in this country by the Poor-law Board, and more especially in the extension of vaccination in Bombay on a purely voluntary system by energetic and indefatigable vaccinators."

4. The efficiency of vaccination as a prophylactic is further demonstrated, by examples of the immunity from small-pox enjoyed by well vaccinated villages or districts, when it was raging as an epidemic in surrounding ill vaccinated places; also by examples of the importation of a case of small-pox into a well vaccinated district, in which, though no particular isolation was observed, the disease did not spread beyond the imported case; and again, by instances of variolous epidemics, which had already invaded a place, being arrested by the prompt vaccination of all who were not protected. These examples, which are very numerous, are supplied by provincial practitioners, among whom may be mentioned Mr. Ceely, of Aylesbury, and other members of the Provincial Medical and Surgical Association.

III. THE STATE OF VACCINATION IN ENGLAND AND WALES is then reviewed by the Committee, who commence their observations on this subject, as follows:—

"A conviction of the value and protective power of vaccination has induced the legislature to pass acts for its extension. The working of these enactments, and the present state of England and Wales with regard to vaccination, have been subjects of the most earnest inquiry by this Committee; and we now proceed to lay the results before you.

"An exposition of this kind is the more urgently required, inasmuch as there is reason to believe that the most serious errors prevail respecting the extent and nature of the legislative provisions made to secure the vaccination of the population, and especially because, as so many years have elapsed since the great discovery of Jenner, and as several acts of Parliament have been passed to promote vaccination, the notion might naturally arise, that, as small-pox still commits such ravages among us, this mortality must have been owing rather to a failure in the protective powers of vaccination, than to any want of its diffusion.

"The only general provision for securing the vaccination of the population is the act of 1840, entitled, 'An Act to extend the practice of Vaccination', as amended by a second act passed in 1841. We have reason to know that an idea prevails to some extent, and even in official quarters, that the National Vaccine Establishment has powers for insuring the vaccination of the people. This erroneous inference renders it incumbent on us to explain that that institution, although it has rendered great service to the community, is, in virtue of its powers, simply and exclusively engaged in supplying lymph, which, as the annual reports show, it has effected to a very large extent. As to the actual practice of vaccination, this is confined to London, and is only carried on there for the purpose of obtaining the necessary supply of lymph, not for securing the vaccination of the population.

"There are two other institutions engaged in providing for the supply of lymph, the Royal Jennerian Society, and the Small-pox Hospital, both of which are supported by private contribution, and have no powers conferred on them by the Legislature.

"The Act of 1840-41, applies to England, Wales, and Ireland, but not to Scotland, for which country no legislative provision has been made. The principal provisions are as follows:—

"1. Boards of Guardians are authorised and required to contract with their medical officers or other practitioners for the gratuitous vaccination of all persons resident in their re-

spective unions or parishes, the expense being defrayed out of the poor-rates.

"2. A copy of the contract so made is required to be transmitted to the Poor-law Board, who have power within the period of fourteen days of the receipt of the contract, to annul the same, if they see fit.

"3. The Poor-law Board are empowered and required to issue regulations, which are binding on the guardians.

"4. The public vaccinators appointed as above, are required, from time to time, to report the number of persons vaccinated by them. The practice is, that the books of the vaccinators are laid before the guardians at each of their meetings, which are held weekly or fortnightly.

"5. Inoculation with variolous matter is declared to be an offence, punishable by imprisonment for any term not exceeding one month.

"6. Vaccination, as performed under this Act, is declared not to constitute parochial relief or alms.

"When this Act was passed, the Poor-law Commissioners were in existence, and to them was intrusted the administration of the measure in the whole of the United Kingdom (Scotland being, as above stated, excepted).

"But in 1847, the constitution of the Commission was altered, and at present the Act is administered in England and Wales by the Poor-law Board, and in Ireland by the Poor-law Board of that country.

"This enactment has now been in force thirteen years; sufficient time has thus been afforded for judging how far it has realised the intention of the Legislature in securing the proper vaccination of the people of the United Kingdom. As regards England and Wales (to which the present Report more particularly relates), we have had ample opportunity of ascertaining the results, and we expect in a short time to be able to present to the Council an exposition of the existing state of vaccination in Ireland.

"The most important source of information to which we have had access, as illustrating the actual state of vaccination in this country, consists of the Reports of the Poor-law Board, and of the annual returns forwarded to the Board from every union and parish in England and Wales.

"But, before proceeding to detail this information, we will give a short sketch of the proceedings of the authorities charged with the administration of the Act of 1840."

The Report then reviews these proceedings up to the present time, including, of course, the subject of fees paid to medical men. It appears that in England and Wales, the fee for each successful case varies from 1s. to 2s. 6d., never falling below or rising above these sums. The average payment per case for the eleven years, 1841 to 1847 inclusive, has been 1s. 5½d. In Ireland, the payment is still lower, generally 1s., often 6d.; in three or four instances 3d. and 4d. The Report notices and justly condemns a most vicious system, which obtains in a few unions in England and Wales, but is almost universal in Ireland, of paying a larger sum for a given number of cases, as 50, 100, or the like, and a smaller sum for all above. It then continues:—

"According to the information we have received, it is found, as might be anticipated that, on the whole, vaccination is more efficiently carried out in those districts where the higher fee of 2s. 6d. is paid; or where, as in large towns, the number and proximity of children requiring vaccination compensate the vaccinator in some degree for a lower payment. Our inquiries also enable us to state, that many public vaccinators deem the usual fee too low; and the consequence is, that vaccination is often delayed till a large number of cases have accumulated, or till small-pox has broken out in the locality, a mode of procedure which it is obvious must often lead to a sacrifice of life.

"It is incumbent on us to state further, that from various quarters we have received information that the exertions of the public vaccinators are not unfrequently discouraged, by members of Boards of Guardians remonstrating whenever any large number of vaccinations had been reported; and we cannot but record our apprehensions, that objections such as these have a tendency to check the efforts of medical officers, and thus to act prejudicially on the public welfare."

In proceeding to their review of the state of public vaccination in England and Wales, the Committee state this fundamental proposition—that the real test of the efficiency of any system of public vaccination is

total number vaccinated under it, but the number vaccinated *within a given period after birth*. The importance of attending to the age at which this operation is performed receives the most ample illustration at the hands of the Committee, and constitutes one of the most valuable features of their Report. They shew that 11 per cent. of the total mortality from small-pox occurs under the age of four months; 25 per cent. under one year; from 51 to 57 per cent. under the age of three; and from 75 to 80 per cent. under the age of five. Thus, of 58,006 persons who died of small-pox in Ireland from 1831 to 1841, 45,826 were under the age of five. Applying these results to the system at present pursued in this country, they shew that, while the total number vaccinated by the public vaccinators falls far short of what it should do under better arrangements, more than half of those who are so vaccinated are not done until after they have attained the age of one year. Thus, in 1852, in England and Wales, while 194,089 children were vaccinated under the age of one year, no fewer than 203,039 were vaccinated above that age: that is to say, for one year after birth at least, they had gone wholly unprotected, although one-fourth part of the total mortality from small-pox occurs within that period. And of course the case is still worse when the operation is still further delayed, as is found frequently to occur, till the child has attained its second or third year. This enormous evil is found to prevail, though in different degrees, in all parts of the country; and the Report gives a variety of illustrations of the prejudicial results of it, and shews how totally unnecessary it is.

The Committee appear to have been struck with the great, and indeed unaccountable, discrepancies found to exist in the various unions and parishes, with regard to the state of vaccination.

"On reviewing the Poor-law Returns, the first thing that strikes the inquirer is the extraordinary difference in the several unions and parishes, especially in the agricultural districts, as to the numbers vaccinated in proportion to the numbers born. These differences cannot be explained by peculiarities connected with one set of unions as contrasted with another set; they do not, for example, depend essentially on the poverty or wealth of a population; nor on the character of a district, whether it is manufacturing or agricultural; nor even on the fee paid to the vaccinator for each successful case. All these may, and doubtless do, operate to a considerable extent, but they are not the determining causes of the relative condition of vaccination. We have found, for instance, that unions under the same general conditions of wealth, employment, and remuneration to the vaccinator, present marked differences as to the vaccination of their population, manufacturing districts compared with manufacturing districts, rural unions compared with rural unions, etc. There are doubtless modifying peculiarities in some unions, such as the practice of vaccinating at dispensaries, at ironworks, in clubs, and so on, where other than the public vaccinators are employed; but these circumstances can have but a limited influence in the kingdom at large. Still, on the whole, it will appear that vaccination is more neglected in rural districts than among town populations.

Then follows a comparison between the numbers vaccinated in Birmingham, Manchester, and other large towns, with the number vaccinated in about twelve rural districts; the results of which are explained in the following comment:—

"Although all these instances indicate great neglect, inasmuch as in the eleven towns enumerated, no fewer than 7,815 persons in twelve months were vaccinated above the age of one year, still the balance, as indicated by the percentage of vaccinations under one year to the total births, is much more favourable than in the case of the twelve rural districts."

In the towns, the births in 1851 being 38,603, there were vaccinated *under* the age of one, 18,359; and *above* that age, 7,815; in the agricultural districts, the births being 6,983, there were vaccinated *under* the age of one, 978; but *above* that age, 2,996.

"The inspection of the tables in the Appendix will reveal instances of the inefficiency of the present system in individual unions in every part of the kingdom. We shall here insert a few examples for the sake of illustration, in considering which,

it must be borne in mind that the numbers in the second column, those showing the vaccinations above one year of age, are all indicative of previous neglect."

Then follows a table, illustrating neglect in individual unions, for the year ending 29th September, 1851; from which

"It appears that in thirty-two unions, in various parts of England and Wales, in which the births were 17,718, there were only vaccinated altogether in 1851, 6,174; and that of these only 1,410, or less than 8 per cent. of the births, were under one year of age.

"The results of such a condition of things are exactly what might be anticipated. When small-pox is imported into a locality thus situated, it finds and carries off a number of unprotected victims; the people are then roused from their apathy, and active exertions are made to obtain that protection which, had it been timely secured, would have altogether prevented the spread of the pestilence. The consequence is, that under these circumstances we frequently find the vaccinations, in a given year, largely in excess of the number of births; and we have thus at once a proof and a measure of the previous neglect. It is so important that this subject should be comprehended in all its bearings, that we here subjoin some instances selected from the Returns to the Poor-law Board.

"In 1850, in consequence of the small number of persons vaccinated in the St. Alban's Union, the Board wrote to the guardians, and at the same time called attention to the fact that some twenty deaths from small-pox had taken place. The state of things will be best understood by the following figures."

The figures shew that in this union there were in the year 1850, 562 births, 73 vaccinated under one year, and 84 above one year; whereas, in the following year, 1851, there were 581 births, 267 vaccinated under one year, and 1,483 above one year; proving that all these 1,483 had been previously neglected. Similar occurrences are also detailed in King's Norton Union and parish, and in Windsor Union.

"The state of vaccination in the metropolis, as will be seen by referring to the Appendix, where the returns for each union and parish are inserted, as might be anticipated, is somewhat more satisfactory than that of the provinces, though even here very great neglect exists.

"The total number of successful vaccinations in the metropolis in 1851 amounted to 36,487, of which 26,854, or about one-third of the total births, were under one year of age; so that 9,633 were vaccinated above that age. In this and other similar cases, it is proper to explain that in all large towns there is a considerable influx of unprotected persons, strangers to the locality, who, on being vaccinated, are of course entered in the second column; this circumstance, however, only changes the neglect from one district or part of the kingdom to another."

The Committee terminate their observations on the official returns with the following important paragraph:—

"We cannot quit this part of our subject without stating to the Council, that the numbers returned to the Poor Law Board as successfully vaccinated tend, to a certain extent, to give us a more favourable view of the actual state of efficient vaccination in England and Wales than is really the case, and that they do not represent, in every instance, the numbers which have been really ascertained to have passed regularly through all the stages of the vaccine disease. It is quite needless to remind them that, in conformity with the doctrine laid down by Jenner, and confirmed by all subsequent experience, unless these stages have been passed through in the normal way, the recipient of vaccination cannot be held as protected against a future attack of small-pox; and in determining that payment should be made only for successful vaccinations, the Legislature doubtless intended that the success should be ascertained in every instance by the personal inspection of the vaccinator, or of some competent person. Generally speaking, this is done; but in consequence of the difficulty in many cases of inducing poor people to give a second attendance, and the impossibility that the vaccinators, hard worked and underpaid, should follow them to their own homes, the practice prevails in many places and districts of entering all as successfully vaccinated who do not return to have their arms inspected. We have ourselves conversed with vaccinators who pursue this plan, and who justify it on the ground that they

have almost invariably found, when they have instituted an inquiry into the reason of a person not returning for inspection, that it has been because the operation was successful; and they have said, that if they were to pursue the opposite course, and report those only whom they saw a second time, the returns would give a far more inaccurate view of the state of the population, as to protection from small-pox, than they do at present. These statements may be perfectly correct, but do not take away at all from the argument for the necessity of inspection; for though it may be quite true that in the majority of cases of this kind the vaccine influence has had its complete effect, there is as little doubt that in many it has failed entirely; while in still more it has produced only a spurious result, a vesicle running an irregular course, sufficiently like the genuine disease to lull the parents of the child into a false security, but perfectly inefficient as a prophylactic against small-pox. *Under any circumstances there is doubt, where there ought to be certainty; and we are ourselves so convinced that the security of the public entirely depends upon their having passed through the genuine vaccine disease, that we think the inspection of the vaccinated at the proper period one of the most essential points to be provided for, and the want of due provision to secure it, one of the greatest defects of the present system.*"

Many cases of gross neglect of vaccination for years together, are mentioned by correspondents.

For instance, Mr. White, of Taunton, says, "Vaccination has become almost extinct in this part of the country." In his district of six parishes, with a population of between 4,000 and 5,000, not one case has offered for vaccination for the last two-and-half years.

Mr. Kimmell, one of the medical officers of Warwick Union, complains of the inefficiency of the Vaccination Act, in consequence of the inadequate remuneration. No medical man will take the trouble; hence, thousands who are vaccinated are never inspected afterwards, and numbers never pass through the disease at all.

Mr. Evans, of Dolgelly, complains of the difficulty of getting parents to bring their children for inspection after vaccination: great evils result from this. Spurious vaccination is put down as effective: on one occasion, he saw as many as nine spurious cases in one day. He desired the parents to meet him again some months afterwards, that the operation might be repeated: not one of them has done it, though this was some years ago. These children, he observes, are as amenable to small-pox as though they had never been touched.

Dr. Star, of Brighton, on a recent outbreak of small-pox at Hove, inquired as to the unvaccinated; and, in a population of 5,000, found 230 to do. What was worse, he found how carelessly and ineffectually many of those reputed to have been vaccinated had been done. He found several families of five or six, from ages of four to eleven or twelve, who had been done and registered, but whose arms presented not the least marks of a cicatrix. On his vaccinating them again, the vesicles ran a regular course, and proved perfectly genuine.

IV. CONSEQUENCES OF THE NEGLECT. "If from this survey of the state of vaccination in this country we now proceed to consider its results, we find them in the fact, which we have already stated, that the proportion of deaths from small-pox to the total mortality is several times as great in this as it is in most of the other European countries. From the annual and other reports of the registrar-general, and from various documents with which we have been favoured by him, it appears, as will be found stated more at length in the Tables on Small-pox in Great Britain and Ireland, appended to this Report, that the average mortality from small-pox in London on a period of thirteen years, has been 913 per annum, and that it is the seventh of all diseases in the order of fatality. In Ireland, for the ten years ending 1841, it was the second in the order of fatality; typhus-fever alone carried off more victims. During this period, as we have already mentioned, it destroyed in that country 58,006 persons. In England and Wales, the total deaths in eight years were 60,691; or, on an average, 7,586 deaths annually.

"Neither the Returns of the Registrar-general in England, nor those of the Census Commissioners in Ireland, enable us to state what proportion of these deaths occurred in the vaccinated and what in the unvaccinated; but with regard to a large por-

tion of them, varying from 75 to 80 per cent. of the whole, there can be no doubt that, with scarcely an exception, they must have occurred among the unprotected, for they all took place under the age of five; and it is allowed by all authorities, that nothing is more rare than a death from small-pox in a vaccinated child under that age. Of the portion (20 to 25 per cent.) in which death took place above that age, there can be as little doubt that the vast majority were unprotected, but we have no sufficient data to determine what the exact proportion may have been.

"But it is not the fatality only which is to be regarded; every one of these deaths is the representative of a certain number of cases, in which the disease, with all its attendant anxieties and perils, may have suffered the patient to escape indeed with life, but may have left him in many instances disfigured, and often not without having developed the seeds of strumous and other diseases in his system. If the modified as well as the unmodified form of small-pox be taken into account, it is a very moderate estimate that there must have been six cases for every death; a computation which would give us 34,800 cases as occurring annually in Ireland, and 45,516 in England and Wales; and if some addition be made for Scotland, for which country there are no official returns, the annual average of cases of small-pox for the United Kingdom will not fall short of 100,000. Such is the humiliating result of our own apathy fifty years after the discovery of vaccination."

V. CAUSES OF THE NEGLECT. These are stated by the Committee to be mainly ignorance, prejudice, and apathy. They do not believe that there is any rooted objection to the practice in the minds of the people, either on religious or other grounds; and they think that this is sufficiently proved by the readiness with which vaccination is accepted by all as a safeguard under the influence of alarm.

VI. CONCLUSIONS. The chief—and, we may add, the unanimous—conclusion of the Committee is, "that no measure, which does not render vaccination compulsory, in some form or other, will be sufficient to ensure the efficient protection of the population of this country from the ravages of small-pox." They leave it to the Legislature to determine the mode.

They consider that all vaccinations should, except under special circumstances, be performed within three, or at most within four, months of birth: and that the registration of births should be made the foundation of the machinery for the registration of vaccinations.

A variety of other suggestions, of greater or less importance, we pass by, and come to the following, which we cannot too strongly commend to notice.

"We deem it our duty to protest against the seventh* clause entirely, as unjust towards the already underpaid public vaccinators; and we suggest that the wording of the first clause must be so altered as not to interfere with the rights of private practitioners.

"We trust that the whole subject of the remuneration of the public vaccinators will receive the earnest attention of the Legislature. Such attention is the more called for, inasmuch as, first, the payment for their present services being already inadequate, it is contemplated by the Act to impose upon them additional and onerous duties; and secondly, because it is obvious that no provisions, however penal, can secure the desired object, unless the pecuniary remuneration be in some degree commensurate with the importance of the services demanded.

"We have already stated our strong conviction that proper means should be taken to ensure the inspection, at the proper period, of all who have been submitted to the operation of vaccination.

"We are of opinion, in order to ascertain the actual progress of vaccination in all points of the country, that more frequent periodical returns to the central authorities than are at present furnished will be indispensably requisite."

Finally, the Committee state that these suggestions are only such as are called forth by the occasion, and do not contain any exposition of what, in their opinion, should constitute a national system of vaccination. They further state that they are preparing a report on the pathological questions connected with the inquiry.

* Now the fifth in the amended bill.

MEMORANDUMS MADE IN IRELAND IN THE AUTUMN OF 1852.

By JOHN FORBES, M.D., F.R.S., Hon. D.C.L. Oxon, Physician to Her Majesty's Household. With a Map and Illustrations. Two vols., 8vo. London: 1853.

We gather from our correspondence that a large number of our members propose to combine in one holiday a short tour in Ireland and a visit to the Dublin Exhibition, with attendance at the approaching anniversary meeting of the Association. The scheme is an excellent one; and to those who intend to adopt it, we strongly recommend the perusal of Dr. Forbes's Memorandums.

Dr. Forbes writes in a forcible, correct, and simple style. His pages are graphic pictures of the scenes and incidents of his journey. It thus happens that, when we draw conclusions similar to, or of an opposite nature from those which are drawn by him, we equally and always feel that we have a true and unprejudiced witness to deal with, and that we may reason on the data placed before us. This very absence of prejudice sometimes, we think, amounts to a too cautious abstinence from expressing strong opinions on contested religious and political questions. A reader is kept alive, and is rarely displeased by the warmth of a moderate advocate; whereas calm and balanced periods are often found to be unsatisfying and unimpressive. For example, we think that, in speaking of the confessional, Dr. Forbes is liable to be misunderstood by the hasty reader: nay, we find that even our Argus-eyed contemporary, the *British and Foreign Medico-Chirurgical Review*, has nodded over this portion of the Memorandums. Whatever may be the Catholic partialities of Dr. Forbes, our contemporary has misstated his views on the subject of confession, in saying that "Dr. Forbes passes a marked though temperate encomium on the practice of confession"; and in further inferring that he even "advocates the practice". We have carefully read the passages in which the subject of confession is noticed; and we can detect nothing in them bearing out such statement or inference. At the same time, we can understand a rapid reader carrying off an inaccurate impression of the author's sentiments.

Without pledging ourselves to the opinions of Dr. Forbes, we commend his volumes, as full of entertainment and instruction.

PERISCOPIC REVIEW.

PRACTICE OF MEDICINE AND PATHOLOGY.

TREATMENT OF TAPE-WORM BY THE MALE SHIELD FERN (LASTRÆA FILIX MAS.)

In our PERISCOPIC REVIEW of 11th of February, p. 134-5, we gave an account of the interesting experiments performed by Dr. Küchenmeister, with the view of determining the relative value of the various vermifuges in common use. On referring to that paper, it will be found that kousso was proved to be the most rapid poison to the tape-worm. Regarding pomegranate bark and male fern root, it was said that "their failure may be owing to the habit of administering a laxative in from four to six hours after the exhibition of the vermifuge, by which the latter may be carried beyond the worm". A paper in the current number of the *Monthly Journal of Medical Science*, by Dr. Christison, of Edinburgh, recalls our attention to this subject. Dr. Christison's communication is the sequel of one upon the same subject published in June 1852.

The preparation employed by Dr. Christison is the aleo-resinous extract obtained by ether from the root. He has administered it with uniform success; and in twenty cases communicated to him he states that the result was also favourable; and he remarks, that his "experience corresponds precisely with the much more extended observation of Peschier, at Geneva, more than a quarter of a century ago." As the male shield fern is a common indigenous plant, it is of no small importance for the practitioner to know that it yields a remedy superior even to the vaunted kousso.

The following is an extract from Dr. Christison's paper:—

"In every case without exception the worm was discharged after a single dose, and usually in one mass. In some it was brought away without any laxative, and occasionally in that

case with very little feculent discharge accompanying it. For the most part there was no pain or other uneasiness, either before or during its action. This was the case even in an instance in which the tendency to the disease had existed for no less than seventeen years, and in which the worm evacuated was the largest and strongest I have ever seen. Several patients, who had often previously used other anthelmintics, have noticed this absence of uneasiness during the action of the male shield fern, as something different from what they had experienced invariably before. It must be allowed, however, that several other individuals have complained of griping, sickness, or indescribable discomfort in the abdomen, and sometimes even of vomiting. But it admits of question, whether these occurrences depend on any direct action of the remedy on the human body, or upon the disturbed condition of the worm under the poisonous operation of the remedy on it. In fact, we have yet to learn that the male shield fern exerts any action on the human stomach or intestines, in the course of its deadly action on the parasitical inhabitants of them.

"In only two cases have I heard of the disease having reappeared; and in both, the interval has been about six months. Of course, there may have been others which I have not heard of. When the worm does not show itself in the discharges for some months after the effective operation of the remedy, I think it is more consistent with reason to say that the disease had returned, than to hold with some that the cure was imperfect, that ova were left to reproduce the worm, or that the head had remained to sprout again and renew the multitudinous joints behind it. Nevertheless, I have latterly advised the subjects of tænia to repeat the dose of the extract once a month for a little, until joints shall have ceased for some time to appear. In none of these cases have any joints been subsequently seen in this way. But it is a very simple precaution to take occasionally a remedy so little disagreeable. A patient, as to whom I was consulted by Dr. Graham, of Cupar, had been liable to a return of the disease every few months for nearly twenty years, during most of which time he was in the army, and got oil of turpentine, with partial success, from the successive medical officers of the regiments in which he served. In this instance, I have recommended an occasional dose of male shield fern as a security. The first dose brought away a very large worm without occasioning any inconvenience; and no joints had appeared in the discharges eight months afterwards.

"At first, I gave eighteen grains for a dose. But afterwards, and, I admit, without any reason, except a desire for greater certainty, I have advised an increased dose of twenty-four grains. On the whole, there has been less complaint made of uneasiness during the operation of the remedy since the larger dose has been used—possibly because the worm is killed more speedily, and that the drug has no inconvenient action of its own upon the human alimentary canal, although given even in the larger quantity.

"It was stated above, that the ethereal extract of male shield fern had not failed in a single instance to bring away the worm with the first dose. In one case, which occurred in this city, it did seem to fail. But on repetition of the trial, with an extract prepared under my own instructions and superintendence, the effect was complete and speedy, as in all the other cases. On proceeding to inquire into the circumstances of the previous trial, I found that the extract had been obtained from a druggist, of unquestionable skill, who had made it for the first time; and it appeared that his preparation was of firmer consistence and more resinous-like than what I had been accustomed to use and recommend as made by another druggist in Edinburgh; and its taste was decidedly different. This imperfect extract proved to have been prepared from powdered root obtained from London; so that it was reasonable to conclude that the wrong root had been collected, or that it had been incorrectly dried. I believe that every druggist in good business in Edinburgh can now supply the genuine article."

We may remark, that the "male fern oil" is the favourite remedy for tape-worm with many English practitioners.

ADMINISTRATION OF FOOD AND MEDICINE BY THE RECTUM.

In a communication read to the Medical Society, and published in the *Medical Times* of June 18th, Mr. H. SMITH makes the following remarks, in the truth of which all doubtless concur, though perhaps all may not act up to it upon every occasion.

"When it is the object merely to support the frame and supply nourishment, and when there has not been any loss of

blood or any previous serious depression, strong beef-tea is doubtless the best thing to use. But if there has been severe hemorrhage, and it is required to rouse the patient from dangerous collapse, the mixture which is to be thrown up should consist of equal parts of beef-tea and brandy. Great care should be taken not to inject too much fluid at one time, otherwise it will excite the bowel and be rejected, and do no good. From four to six ounces is the quantity I have been in the habit of using; the whole of this will, in all probability, be absorbed. If necessary, the injection may be repeated in the course of four hours. It is desirable to inject it as high up as possible; and, therefore, a long elastic tube should be used, and passed along the bowel as far as it will go with safety. I need not mention, that it would be well for the practitioner to use the injections with his own hands; for, indeed, the circumstances which call for their use always demand his continual attendance."

NATURE AND TREATMENT OF HOARSENESS.

The following is an abstract of the views of M. TROUSSEAU on the above subject, as given in the *Journal de Médecine et de Chirurgie Pratiques* for last February:—

Hoarseness almost always depends on hyperæmia of the laryngeal mucous membrane; but, in order to cure this condition, not only must it be attacked in its seat, but the circumstances in which it has been produced must be ascertained—whether it is a continuation of inflammation of the pharynx, mouth, or nasal fossæ, in which case it may be often sufficient to apply remedies to these parts.

Among the inflammatory affections of the pharynx which are most frequently propagated to the larynx, is chronic or follicular pharyngitis; the characters of which are enlargement of the mucous follicles, slight edema and redness of the velum palati, with a certain amount of elongation of the uvula. This form is almost always of rheumatic origin, and appears at the end of an attack of apyrexial rheumatism which has lasted three weeks or a month. It recurs a great number of times, and leaves its effects on the pharynx in the form of hypertrophy of the mucous follicles. Generally, however, the inflammation of the pharynx itself proceeds from the mouth or the nasal fossæ. Thus, just as in the child the cutting of a tooth will produce cough by extension to the bronchi of the inflammation of the gums, carious teeth will produce an analogous affection in the adult, by producing a change in the voice which is only removed by the extraction of the diseased tooth. Cases of this kind frequently came under the notice of M. Trousseau. A distinguished *cantatrice* lost her voice for two years, and recovered it only after two wisdom-teeth had been extracted.

There is also an eczematous affection of the nasal fossæ, which is easily propagated to the pharynx, the Eustachian tubes, and the larynx. There are also persons who are constantly the subjects of nasal catarrh; and in these the catarrh is propagated to the pharynx and larynx. The vocal cords, softened by the thickening of the mucous membrane, then cease to vibrate, and mucus is deposited in the ventricles of the larynx.

Treatment. If the pharynx is the primary seat of the disease, M. Trousseau employs strong stimulants to that region. The best of these is a solution of one part of nitrate of silver in three of water. This is applied daily for a week, by means of a brush, to the arches of the palate, to the palate itself, and to the tonsils. It is afterwards repeated three times, twice, and once a week; and once a fortnight for some months. This treatment should be applied more perseveringly in proportion as the hoarseness is of old date, and should be continued after the voice has returned, without, however, paying regard to the hypertrophy of the follicles, which sometimes lasts for an indefinite period after chronic pharyngitis. If, from any reason, this mode of treatment cannot be adopted, the patient should be taught to accustom himself to touch the pharynx with the index-fingers—the right finger for the right side, and the left for the left side. When this can be done, the patient will be able to apply with his fingers a powder composed of one-fourteenth of a grain of white precipitate and ten drachms of powdered sugar. If this remedy, which is very effectual, fail, alum gargles may be used. Many singers use the gargle of Bennati, an old Italian physician, half an hour before entering on the stage, when they are labouring under hoarseness from subacute inflammation. The following formula is given by M. Trousseau: Alum, from 10 to 30 parts; water, 500 parts; honey or mulberry syrup, 100 parts. Whatever gargle is employed should be used as hot as it can be borne; cold gargles are useless.

In a very large number of cases, the pharyngeal affection is of a herpetic nature. In a person, for instance, who has had eczema of the nose, the disease may have produced union of the nasal fossæ with the pharynx and the Eustachian tube; thus giving rise to obliteration. If eczema of the nose is still present, and coryza appears under the influence of cold or after meals, the hoarseness must be treated by applications to the nasal fossæ. One part of sulphuret of potassium is dissolved in one hundred parts of water, and a tea-spoonful is put into some very hot water, and forcibly inhaled by the patient for some minutes, three times a day. The same solution, in a larger proportion to the water, is to be used at the same time as a gargle.

In cases of this nature, sulphureous waters also are very useful, taken two or three times a day. The patients may also be made to take into the nose small pinches of white or red precipitate.

Some changes in the voice are only to be benefited by direct treatment, viz., inhalation of arsenic, and cauterisation with a strong solution of nitrate of silver. Cauterisation is sometimes difficult; and in this case, the use of arsenicated cigarettes is more simple, and not less efficacious. The cigarettes are made with one part of arsenite of potash to twenty-five of water: in this some filtering paper is dipped, then rolled into cigarettes, and dried. These must be smoked slowly—eight or ten inspirations each time, three times a day. The metallic arsenic is condensed on the larynx.

SURGERY.

POLYPI OF THE RECTUM.

The following is an abstract of an article by M. A. FORGET, in the *Union Médicale* for June 21st:

Polypus of the rectum is a disease of which very few cases have been recorded. M. Dufresse-Chassaing related two instances to the Surgical Society of Paris: the following is a brief history of them.

CASE I. In a boy, aged 14, the polypus was as large as a cherry, and was two centimètres above the anus: it was pedunculated. With each stool, there was an escape of blood: hence the patient was pale, and much weakened. M. Dufresse pulled down the tumour, and applied a double ligature to the pedicle; he then divided the latter below the ligature. A short time later, the threads were evacuated with the fecal matter. There was no more escape of blood; and the boy began to regain his health and strength.

CASE II. In a strong, healthy child, aged two years, who had never passed blood by stool, M. Dufresse found the anus blocked up with a small tumour. In exercising slight traction on it, to discover its origin and point of adhesion, its pedicle broke at the point of union with the tumour. A little blood escaped, and the child recovered without any unfavourable accident.

From an examination of the different cases of rectal polypi which have been described, M. Forget describes the following forms as capable of occurring.

1. *Mucous polypi*, produced by hypertrophy of the superficial layers of the mucous membrane, having a limited attachment, of small depth, and rarely returning after removal. According to researches, these polypi have but few vessels; they have epithelium on the surface, then a tissue without regular structure; it is difficult to find there some fibres of cellular tissue in the midst of the amorphous mass, which is of a more or less marked red colour.

2. *Fleshy polypi*, also called sarcomatous, or vascular. They arise from hypertrophy of the entire thickness of the mucous membrane, with its vessels and glands. They are composed of cellular tissue, numerous vessels, fibroid tissue or fibro-plastic elements, and an epithelial layer on the surface.

3. *Cystic polypi*, arising from simple glandular hypertrophy. The follicles of the intestine become obliterated, and are transformed into cysts, which, in growing, become provided with pedicles. These polypi are generally numerous. M. Robert removed, in the Beaujon Hospital, at least thirty of them from a girl: they were small, isolated, and globular. Under the microscope, they presented an epithelial mucous layer on the surface; and there were also very plainly present all the different elements composing the intestinal glands.

4. *Fibrous polypi*, the results of hypertrophy, or rather products of the submucous fibrous tissue. They belong to the intestine.

5. *Fibrous bodies of the rectum* are developed externally to the rectum in the recto-vaginal space.

M. Forget believes that the ligature is the only mode of treatment admissible, as a general rule, in the treatment of polyp of the rectum.

DIVISION OF THE TENDO ACHILLIS IN THE TREATMENT OF FRACTURE.

At the meeting of the Royal Medical and Chirurgical Society, on November 27th, 1849, Mr. CAMPBELL DE MORGAN brought forward the subject of division of the tendo Achillis in certain cases of fracture of the bones of the leg. The object was evidently to overcome the displacement caused by the action of the muscles of the calf.

In the *Lancet* for February 12th, 1853, we find the following remarks:—

"The division of the tendo Achillis, as a means of facilitating the reduction of fracture of the leg, in cases where such reduction presents difficulties, seems now to be pretty generally used in our hospitals. This practice, which originated in Germany, and has been adopted in several countries besides England, has the great advantage of allowing of reduction without the powerful traction (and accompanying pain) which must sometimes be used in cases of complete riding or widely displaced fragments, when the gastrocnemius muscle draws the lower fragment upwards with a great degree of force.

"Mr. SHAW has a male patient, aged forty years, who was admitted January 19th, 1853, with a simple fracture across both malleoli, with complete twisting of the foot outwards and towards the front of the leg. Reduction was found extremely difficult, and Mr. Shaw thought it advisable to divide the tendo Achillis, to render the parts more yielding and manageable. This measure had the desired effect, and the leg was easily reduced; the limb was then placed into the usual apparatus (side-splints and foot-piece), and the patient is now doing extremely well.

"A severe case of compound fracture of the leg was admitted October 20th, 1852. The patient was sixty-one years old. He was run over by a cab, and suffered a compound fracture towards the lower third of the leg. The fragments were so widely separated, and the action of the gastrocnemii and solei muscles so powerful, that Mr. Shaw divided the tendo Achillis, besides removing a small portion of bone. Reduction became then comparatively easy. Suppuration has been profuse, and the diligent exhibition of stimulants became necessary; but, by dint of care, cleanliness, etc., the patient has done well, and the wound was almost healed three months after admission.

"Mr. HILTON had lately recourse, at Guy's Hospital, to the division of the same tendon in a case of compound fracture of the leg of a very severe kind. Reduction was found extremely difficult before tenotomy was performed, as the separation of the fragments was considerable, and the traction of the muscles insurmountable. After the division of the tendon, the limb was secured in a favourable position; and, by the use of opium and stimulants, the patient is likely to recover.

"Mr. Hilton had two other cases of the same description, in which tenotomy proved very beneficial. One was that of a woman, sixty-seven years of age, who was admitted with compound dislocation of the ankle-joint. Mr. Hilton proposed amputation, but the patient would not consent; he was therefore obliged, in order to bring the parts into tolerable apposition, to divide the tendo Achillis, the peronei tendons, and that of the tibialis anticus. By the continued use of stimulants, etc., the patient recovered.

"A woman suffered simple fracture of the lower third of the tibia and fibula. The foot became so everted by the action of the peronei muscles, and the lower fragment was so strongly pulled upwards, that Mr. Hilton divided the tendons of the peronei and the tendo Achillis. Reduction was then effected with comparatively little trouble, and this patient has done well."

METHOD OF APPLYING COLD WATER IN SURGERY.

The following is taken from the *Lancet* for January 29th.

The irrigating means hitherto employed at Guy's Hospital has consisted of a receptacle for water (a glass funnel generally, with a cork inserted in its narrow end), suspended as best it could be to some part of the frame of the patient's bed, with worsted threads so placed that one set of ends could be immersed in the water, and the others hang over the part to be irrigated, capillary attraction completing the rest of the intention. Mr. HILTON, observing the occasional inefficiency of this instru-

ment, has had constructed, by Mr. Bigg, of St. Thomas's Street, the following apparatus.

The instrument consists of a zinc reservoir, with a vulcanized India-rubber tube opening from it at its side, close to the bottom. The entrance of water into the tube is regulated by a stop-cock; at the other end of the tube is affixed a broad zinc head, resembling a compressed or flattened rose of a watering-pot, a linear series of perforations being cut through its lower or convex edge. Equidistant from each other, and about half-an-inch apart, threads of worsted are passed through these holes from within, and made to project about three-quarters of an inch below the metal. This end is suspended over the part to be irrigated; the reservoir charged with water is placed upon the usual little shelf situated at the head of the bed, and the stop-cock being turned, allows the water to escape into the tube. The extent and rapidity of the irrigation are, by the aid of the stop-cock, perfectly regulated. A small sheet of oil-silk is placed under the arm and separated from the bed, the oil-silk being so arranged as to conduct the water which has passed over the limb into a basin or upon the floor of the ward. It is obvious that water of any temperature, or medicated in a prescribed manner, may be made, by this simple and cheap apparatus, to distribute itself over any part, however small or extensive it may be. The advantages of this instrument are, that the supply of water can be regulated by a stop-cock, so that there may be a definite and equable amount of irrigation to every part of the injured structure, or to any particular region, which irrigation can be regulated according to the sensation of the patient, or the temperature of the textures under treatment. By enlarging or diminishing, by elongating or shortening, the head, or varying its form, the drops may also be carried simultaneously over a larger or smaller, or any irregularly formed surface.

TOXICOLOGY.

BITE OF THE RATTLESNAKE SUCCESSFULLY TREATED BY LARGE DOSES OF WHISKEY AND AMMONIA.

The beneficial effects of stimulants, especially of large doses of ammonia, in certain poison diseases (such as scarlet fever, hooping cough, glanders, erysipelas, and the prevailing furunculoid epidemic) have been at various times brought under the notice of the profession. It appears, from the subjoined remarks of Dr. T. A. ARCHISON, that diffusible stimulants are equally useful in poisoning from the bite of the rattlesnake. The following is abridged from the *Southern Journal of the Med. and Phys. Sciences* for March 1853, published at Nashville Town.

"On the 20th September, 1852, Dr. Archison was summoned to attend Miss R., aged 17, who had been bitten by a rattlesnake. When he arrived—two hours and a half after the accident—he found her almost moribund, with a pulse wavy, and scarcely perceptible at the wrist. The surface was bathed in a cold perspiration; the pupils were dilated; and the mind was wandering. It was found that the bite had been inflicted upon the instep of the left foot: two little punctures were very perceptible; around which there was a greenish areola, with some puffiness.

"Having heard of the marvellous efficacy of spirits in similar cases, Dr. A. administered half a glass of whiskey, which was swallowed with avidity. The wound was freely scarified and cupped, and the extremities placed in a hot saline bath. Twenty grains of carbonate of ammonia were then given; which were immediately thrown up, together with the contents of the stomach, coloured a bright grass green. A glass of whiskey and twenty grains of carbonate of ammonia were given alternately every half hour, until three pints of the former and eighty grains of the latter were taken. Not the slightest intoxication ensued; on the contrary, the urgent and alarming symptoms gradually gave way, warmth was restored to the surface, the pulse returned to the wrist, the mind was called back from its wanderings, and she fell into a quiet sleep, from which she awoke at five o'clock, A.M., complaining of intense pain in the foot, shooting up the inside of the leg to the knee. She was then ordered, morphia one-fourth of a grain, fomentations of laudanum and camphor, followed by a poultice of linseed, with the effect of entire relief of pain. The following day castor oil was given to move the bowels. From that hour she suffered no further inconvenience from the bite."

The author concludes his paper with the following remarks:

"The instinctive avidity and impunity with which this delicately nurtured young lady took so large a quantity of spirits, sufficient under ordinary circumstances to have killed a regular habitué, would excite astonishment, if we did not reflect that it

was antagonized by the depressing effect of the poison on the nervous system.

"But the most interesting feature in this case remains to be stated. Miss R., at the time she was bitten, was the subject of well-marked hooping cough, which was then epidemic in the neighbourhood; she had had the disease about three weeks, consequently it was at its acme, but on recovering from the effects of the poison, to her great surprise and gratification, her cough had disappeared also, nor did it return."

In connection with this paper, we request our readers to peruse an article on glanders, which we intend to insert in the Periscopic Review of next number.

CASE OF BITE OF COBRA DI CAPELLO: TREATMENT BY AMMONIA: RECOVERY.

Dr. W. CHALMERS, of Brighton, relates the following case in the *Glasgow Medical Journal* for April 1853:—

CASE. On 25th June, 1819, at 11 p.m., Dr. Chalmers heard from the outside of his house, at Barrackpore, near Calcutta, a loud call for his immediate attendance. It proved to be from Colonel Lumley, whom he found with a lantern in his hand, entreating him to come with him at once, as his *mehturane* (female sweeper) had been bitten by a cobra di capello. He took a phial of solution of ammonia, of the usual strength, a case of scalpels, and a large sized elastic gum male catheter. On arriving at the hut occupied by the woman and her husband, he found her stretched outside on the ground, her head resting on her husband's knee. Her body was cold and collapsed; there was neither breathing nor pulse; her eyes were wide open, and insensible to light; the mouth was also wide open; the tongue cold; in fact life was, to all appearance, extinct. How long she had lain in this position could not be ascertained; her husband conjectured an hour at least. On the back of the right hand were discovered two punctures, as if made by a needle, about an inch and a-half apart, marking the entrance of the poisonous fangs of the snake. Upon each puncture there was a drop of nearly colourless fluid, without any hæmorrhage, tumefaction, or ecchymosis.

Here was a case sufficiently discouraging, if not, to all human appearance, hopeless. However, Dr. Chalmers resolved not to abandon the case.

Bricks having been ordered to be heated for application to the præcordia and the feet, the first step of the treatment was to pour down her throat a teaspoonful of ammonia, with as much water, but all power of deglutition being lost, some difficulty was experienced in accomplishing this object. By the aid, however, of the catheter, as an œsophagus tube, he succeeded admirably. The next step was to cut out and pare off the integuments and subjacent cellular and muscular tissues, extending incision about one-fourth of an inch beyond the punctures. From the large wound, which was of an oval shape, not a drop of blood escaped in this operation. The husband was now directed to apply his mouth to the wound, and suck with all his powers, which he proceeded to do most readily, the natives having great faith in such a measure. This he continued, with all the energy he was capable of, for fully half-an-hour, without succeeding in procuring any moisture, while the ammonia was repeated steadily every ten minutes, till a full ounce was consumed. At length their perseverance was rewarded by some hopes of a restoration, for the poor distracted husband leaped up in an ecstasy of joy, exclaiming in his own language, "*Lohpo dàt sahib*" (blood is coming, sir), showing his tongue covered with the vital fluid. In a few minutes more the action of the heart was faintly perceptible; the pulse at the wrist was just traceable in a threadly thrill; she moved her head, gave a deep sigh, and sat up. The only treatment pursued afterwards was the free cauterization of the wound by nitrate of silver,—the application of a pledget of lint dipped in melted resin cerate, covering the whole with a hot poultice. The wound healed kindly by granulation, and she was able to resume her duties in a few days.

REMARKS. In this case the powers of the ammonia were proved most incontestably as a safe and sure remedy in all bites of venomous reptiles. Such is the confidence of the natives in the remedy, and more especially the native soldiery, who in their huts are much exposed to these injuries, that the moment any one gets bitten, he runs to the nearest European officer, calling out for the "*Safed Dawy*", the "*white medicine*", assured that with a few doses of that, he is safe, and disappointment in the curative effects is never experienced. By "*the white medicine*" is meant a preparation of ammonia, which used to be imported in great quantities from England, and generally kept at hand by

every officer,—the old-fashioned *Eau de Luce*, *Liquor Ammonia Succinatus*.

Dr. Chalmers observes, that one cannot help regretting that the medical officers of the hospital into which the unfortunate fellow, who was bitten in the Zoological Gardens last year, was admitted, were not apparently sufficiently acquainted with the powers of ammonia in such cases. If they had been, it would no doubt have been had recourse to.

REPORTS OF SOCIETIES.

EPIDEMIOLOGICAL SOCIETY.

JULY 4TH, 1853.

Dr. BABINGTON, PRESIDENT, in the Chair.

YELLOW FEVER as IT APPEARED IN ANTIGUA IN THE YEARS 1835, 1839, AND 1842. BY THOMAS NICHOLSON, M.D., OF ANTIGUA.

We can only give a few of the leading points of this elaborate and admirably written paper.

Dr. NICHOLSON is of opinion that yellow fever is not a contagious disease. The outbreak of yellow fever in Antigua, in 1835, was preceded by a hurricane, with remarkable changes in the barometer. Dr. Nicholson himself soon became a victim of the disease, and the symptoms which he felt were described. In very malignant cases, blood often exudes through the mucous membranes, and even through the skin. The author recognizes several kinds of yellow fever; he described two varieties, which he called the *ardent* and the *congestive*, with great minuteness. In speaking of the pathology of yellow fever, he observed, that the yellow colour of the skin comes out more distinctly after death; and that the blood is highly fluid, and fails to coagulate. In one case he found frothy blood in the heart, indicating the presence of gaseous matter in the circulating system. The mucous membranes were generally softened in a greater or lesser degree. Dr. Nicholson is confident that yellow fever is different from any kind of endemic remittent fever. It attacks the same person once only in life. Localities, in which there is great heat of sun during the day, and a deposition of dew during the night, are favourable localities for the disease. Venesection, in the first stages of the disorder, is often an excellent remedy.

Dr. GAVIN MILROY said, that one remarkable statement in Dr. Nicholson's paper was, that yellow fever had been absent from Antigua for the long period of fifteen years. Many persons would imagine that after so long a respite, the island could only have received the disease by a re-introduction of it from without, which it had been distinctly shown was not the case. Ships, also, did not bear away the disease from Antigua. It is a curious fact that yellow fever almost invariably occurs in towns, and not in the country. In this it differs from scarlet fever and small-pox, which extend by continuation from towns into country districts.

With reference to treatment, Dr. Milroy observed, that in Jamaica, extreme antiphlogistic measures had been found injurious, while large doses of calomel and quinine had proved of service.

Dr. GAVIN said, the author of the paper had said that there was no true diagnostic symptom of yellow fever in its early stages; but he (Dr. G.) believed that an injected state of the fauces was a good and early diagnostic symptom. The causes of yellow fever were exposure to local miasmata; and the favourite localities of the disease were low, damp, filthy places, and close buildings—just such places, indeed, as those which favour the spread of typhus in this country. In the West India islands, the seats of the disease could be predicated by a careful and experienced observer. Dr. Gavin could not agree with Dr. Nicholson, that, in all cases, Europeans were more liable to yellow fever than the natives of tropical climates; he had seen epidemics in which the reverse obtained.

Mr. RICHARDSON said that there were many points in Dr. Nicholson's paper which are peculiarly interesting to a physiologist and pathologist, though he may not have seen an epidemic of yellow fever. The author had said that, in the dandy fever, which preceded one of the epidemics of yellow fever, arthritic inflammation was an important symptom. This was very curious, for arthritis was sometimes a complication in cases of yellow and scarlet fevers. With reference to the effects of meteorological changes, he (Mr. R.) did not think that such changes had any very great influence over the epidemics of this country; but the remarks of Dr. Nicholson on the great heat of the sun in the day, and the great coldness at night, were

the night, and on the effect of these conditions in causing fever, were of considerable moment. The wonder was, not that the functions of the body became deranged under such changing conditions, but that those functions should in any case remain unimpaired. Here, indeed, a simple physical cause might perhaps be found to account for fever, without having any recourse to the doctrine of miasmatic influences. Dr. Nicholson's observations on the blood of yellow fever patients differed from those of other observers who had found the blood *superfibrinized* in that disease. It was impossible to speak fairly of the treatment of an epidemic disease, without having actually seen the line of treatment pursued; but certainly it does not seem to be a very philosophical proceeding to abstract blood, and to give mercury, in cases of disease in which the blood is already destitute of its fibrinous constituent.

Dr. CAMPS asked if the verberna had proved of use as a medicine in the treatment of yellow fever?

Dr. GAVIN had received extensive accounts of this remedy. It might have some virtues, but he had no faith in it as a medicine positively valuable. He disagreed with a previous speaker as to the effect of meteorological changes: some such changes had a great influence, the changes of the wind especially. In Martinique, the French physicians say that a south wind always brings the yellow fever.

Dr. McWILLIAM said, that Dr. Nicholson was the first author he had met with, who had spoken of a special and non-recurring disease as a non-contagious disease. In some forms of yellow fever, the depressing line of treatment certainly was injurious.

ASSOCIATION INTELLIGENCE.

MEDICAL BENEVOLENT FUND.

At the meeting of the Committee of the Medical Benevolent Fund, June 28, the minutes of the preceding meeting were confirmed, and several matters of business arising therefrom were disposed of. The Treasurer's report was read, from which it appeared that £673:5 had been received in subscriptions during the year, and that £611:10 had been paid in benevolent aid, and £55:0:9 in expenses; making together £666:10:9, and leaving a balance of £6:14:3 in the hands of the Treasurer. Subsequently, £50 were voted to the several cases; thus leaving a balance due to the Treasurer of nearly £45. Auditors of the accounts were appointed, and the Committee then adjourned to the 12th July, to be specially convened on that occasion, to consider the Report. The list of the Committee was revised, and some alterations were proposed, which will be submitted to the meeting of Committee on 12th July.

The following cases were considered and relieved:—

- i. The orphan of a medical man who died abroad, to whom small sums had been previously given, to assist in her education, £5.
- ii. Two ladies, of the respective ages of 42 and 47, the daughters of a well known medical man, who had struggled through narrow circumstances, and were now disabled by disease from acting as governesses, £10.
- iii. The widow and family of a medical man in Derbyshire, in great distress, £5.
- iv. The widow and family of a medical man, to assist in defraying the expenses of emigration, £5.
- v. The widow and family of a medical man, who had known days of affluence and comfort, but were now quite destitute, £10.
- vi. A medical man in the Isle of Wight, disabled by paralysis, with his wife and family, £10, in two half-yearly payments.
- vii. A very aged medical man, a candidate for an annuity, to help him until November, £5.
- viii. A worn-out surgeon (diploma 1807), in great distress, £5.

METROPOLITAN COUNTIES BRANCH:—NOTICE OF ANNUAL MEETING.

The Annual Meeting will be held at Mr. Lovegrove's Brunswick Hotel, Blackwall, on Tuesday, July 19th, at 4 P.M., precisely. The Members will dine together at 6 o'clock. Members who intend to dine are requested to furnish their names to the Secretary as early as possible, and not later than July 10th.

Tickets for the dinner 10s. 6d. each, including ices and dessert.

JOHN FORBES, M.D., President.
T. OGIER WARD, M.D., Hon. Sec.

N.B. Members of the Association become Members of this Branch by paying an Annual Subscription of 2s. 6d.

NORTH WALES BRANCH:—ANNUAL MEETING.

The Annual Meeting of the North Wales Branch of the Provincial Medical and Surgical Association, was held on 21st June, 1853, at Holywell, under the able Presidency of Peter Williams, Esq., M.D. The following Members were present: T. T. Griffith, Esq., (Wrexham); D. Kent Jones, Esq., (Llangefni); G. T. Jones, Esq., (Denbigh); Robert Jones, Esq., (Conway); W. P. Jones, Esq., (Holywell); J. Lloyd, Esq., (Llangefni); T. Morris, Esq., (Marford); Augustus Parry, Esq., (Llanasa); J. Roberts, M.D., (Bangor); O. Roberts, M.D., (St. Asaph) President Elect; E. Williams, M.D., (Wrexham); H. Williams, Esq., (Llansaintffraid); W. Williams, M.D., (Mold). Dr. G. Harvey Williams, (Oswestry) member of the Shropshire Branch; Dr. T. W. Williams, (Denbigh); and James Williams, Esq., (Holywell) were present as visitors.

MEETING OF THE COUNCIL.

The Members of Council present proceeded to arrange the usual preliminaries for the General Meeting; and in the absence of Dr. Hughes, of Mold, the retiring President, who was prevented attending by an urgent professional engagement, T. T. Griffith, Esq., of Wrexham, was unanimously voted to the chair.

Mr. LLOYD, observing a newspaper reporter present, said it was quite irregular at a Meeting of Council for private business, that the latter should sit there; and he was accordingly requested to withdraw, which he immediately did.

NEWSPAPER REPORTERS.

A little after twelve o'clock, just before the usual business commenced, Mr. LLOYD stated that he was sorry to have to call the attention of the Meeting to a subject of a painful nature, but which it was impossible for him to pass over. He had already occasion to draw their attention to the presence of the reporter of the *North Wales Chronicle*, at an improper time; but he had now to lay before them a most serious complaint against that paper, viz., that of not only grossly misrepresenting two members of this Association, but of refusing to give the slightest correction or explanation of the incorrect statements it had published, and even accompanying that refusal with additional abuse. This was the *gravamen* of the charge. Editors of newspapers were no doubt much at the mercy of other parties for their information, and it was useless to expect but that much that was incorrect should find its way into their publications; but it was well known with what alacrity the respectable portion of the press always corrected all misrepresentations. However, here was an instance of the very reverse of this conduct, of so gross a character, showing so much recklessness and hardihood in making and maintaining incorrect assertions, that he felt it would be unbecoming in them to sanction the presence of the representative of a publication which had been guilty of such conduct.

On the motion of Mr. GRIFFITH, the following resolution was unanimously adopted, and an intimation of its purport was communicated to the reporter in question:

"That it is the wish of this Meeting that no reporter from a newspaper be admitted on the present occasion, as it is the intention of the Meeting to draw up for themselves an account of their proceedings, and transmit it direct to the *JOURNAL of the ASSOCIATION*."

PRESIDENT'S ADDRESS.

Mr. GRIFFITH, in vacating the chair, thanked the Meeting for again placing him in that honourable position; and

Dr. PETER WILLIAMS, having occupied it as President of the day, then addressed the meeting in the following words.

Gentlemen,—Not having the gift of elocution like my respected friends and enlightened predecessors in the chair, and without the privilege of their mantle being thrown over me (which should have been done by them), I must crave your indulgence in permitting me to read the little I have to say in addressing you upon this occasion. In taking the chair, which you have done me the honour to assign to me, I beg to offer you my grateful acknowledgements. It is an honour I never anticipated, because I am but too conscious of my not possessing those essential qualifications, desirable and necessary to constitute the important and honourable distinction of "President of the North Wales Branch of the Provincial Medical and Surgical Association". Seeing myself surrounded by gentlemen of acknowledged talents and high professional attainments, I might,

* For a full explanation of this proceeding, vide Mr. Lloyd's letter at page 601.

were I a vain man, indeed, justly feel proud of such a distinction. But, I assure you, gentlemen, I accept the chair with great diffidence—yet not without relying on your kind indulgence, and that you will take the will and the desire for the act and the deed, in attempting, however imperfectly, to fulfil the duties which you have called upon me to perform. In the first place I would heartily welcome this meeting on its assembling for the first time in Holywell, to do honour to the shrine of St. Winifred; an event which, no doubt, will be chronicled in our annals. We meet together as members of a high and honourable profession; to hold friendly converse on medical topics, and for our mutual instruction; to uphold the interests, the honour, and dignity of the profession, and to cement the bonds of friendship by social intercourse; and last, though not the least object—to promote the welfare of suffering humanity; and I hope and trust we shall not relax in so laudable a duty. Amongst the subjects which we anticipate will be brought before us for discussion this day will be one of high and growing interest, viz., the wonders of the Microscope as a novel and powerful means of discovering the pathology of structural and organic disease, and bringing to light many valuable facts hitherto hidden from the naked eye. I again thank you, gentlemen, very sincerely, for the honour conferred upon me, and relying on your indulgence, I now sit down, deeply impressed with your kindness, and with my humble services at your disposal.

REPORT OF THE COUNCIL.

The report was then read; and after a brief discussion, on the motion of Dr. W. WILLIAMS of Mold, seconded by Mr. ROBERT JONES of Conway, was adopted. It referred to matters of Finance; and also alluded to the "Medical Reform Bill" of the Association, on which it sought the opinion of the meeting.

ELECTION OF OFFICERS.

Upon the motion of H. WILLIAMS, Esq., of Llansaintffraid, seconded by G. T. JONES, Esq., of Denbigh, Dr. Owen Roberts, of St. Asaph, was unanimously appointed President-Elect for next year.

Dr. WILLIAMS, of Mold, moved that Rhyl be the place of the next annual meeting. This was seconded by Dr. E. WILLIAMS of Wrexham, and carried.

Dr. J. ROBERTS, of Bangor, moved, and W. P. JONES, Esq., of Holywell, seconded, that a vote of thanks be given to the treasurer and secretaries, and that they be re-elected. This was agreed to unanimously.

MEDICAL REFORM.

Mr. GRIFFITH, of Wrexham, wished that the resolution he had to propose had been entrusted to some one more conversant with the details and progress of the reform measures now in contemplation. At the same time, he felt, in common with all present, a deep conviction of the necessity for such measures, and an earnest anxiety for their success. The great majority of medical men have become unanimous in the feeling, that a change and reform are required to amend the many anomalies connected with the education, position, and influence of those who practise the healing art in this country. Whilst aiming at such a reform, they are sensible that a serious obstacle to their wishes exists in the opposition of the College of Surgeons; and though the opposing body may be numerically small, its opportunities and influences are great, from the circumstance of many of its leading members being in frequent communication professionally and privately with the higher classes of society in London, and thus having it in their power to give a decided bias to the opinions of those who in Parliament are to determine the success or failure of any measure of reform brought before them. Ignorant as most of the members of the legislature must be of the real state of our profession, of its internal arrangements and constitution, its defects and requirements, its varied and unsatisfactory modes of education, and the absence of legitimate tests by which to prove the adequate qualifications of its professing members; they gladly receive from what they justly consider the highest sources of information, such representations, arguments, and opinions as may enable them to give a vote on the question. To remove this ignorance, every professional man should take every opportunity of explaining to members of Parliament the actual position of the profession, the disadvantages under which it peculiarly labours, and an anxious wish to obtain at once such redress as might secure the privileges, protection, and the respectability in status and influence, to which, when not forfeited individually, members of a liberal profession are entitled. He would express a decided opinion in favour of the Bill drawn up by the Council of the Parent Association.

Mr. GRIFFITH then moved the following resolutions.

"That this Branch views with much concern the present very unsatisfactory state of the laws relating to the medical profession in this kingdom: That a petition be presented to each House of Parliament signed by the president and members of this branch of the Provincial Medical and Surgical Association, praying for immediate legislation and suggesting that the bill drawn up by the council and members of the Parent Association and submitted to the Prime Minister and Secretary of State may be the basis whereupon a wholesome measure of medical reform may be enacted."

J. LLOYD, Esq., of Llangefni, having seconded this resolution, it was unanimously carried.

THE RETIRING PRESIDENT.

A vote of thanks to Dr. Hughes, of Mold, Retiring President, was moved by AUGUSTUS PARRY, Esq., of Llanasa, and seconded by T. MORRIS, Esq., of Marford, and carried with acclamation; the meeting expressing their great regret that he was prevented from attending.

CASES AND COMMUNICATIONS READ.

Mr. LLOYD related the history of a singular disease of the nervous system, which appeared to arise from the excitomotor system. The case was characterized by constant convulsions of all the voluntary muscles, similar to chorea, and occasionally at night by fits of violent hysterical convulsions, ending in ecstatic sleep, or a state approaching somnambulism, which lasted till morning. And now commenced the most curious symptom of all, namely, that of constant gaping from morning to night, without the slightest interruption, causing fatigue and exhaustion of the most painful character. Another curious point was, that the faculty of taking food had gradually diminished, until at last the patient had come to take nothing whatever to support life, except a few drops of water once a day. This state of things had lasted for nearly three weeks, bringing the patient down to the lowest state of debility and exhaustion.

Dr. WILLIAMS, of Mold, drew the attention of the meeting to the last volume of Rokitsansky's work, in which there was related a case of constant gaping, which had been benefited by arsenic.

Dr. O. ROBERTS also recommended a trial of this remedy, if the state of exhaustion of the patient permitted.

Mr. GRIFFITH recommended the trial of nutritious enemata, to keep up the strength. He related some interesting cases from his own experience, to show the benefit of such practice.

Mr. LLOYD said, that great difficulty had been found, for some weeks past, in administering such remedies, on account of the great weakness of the patient; every attempt producing violent fits and convulsions.

Various other cases were alluded to by different members, forming the subjects of animated conversation.

THE JOURNAL

Formed the subject of conversation. No specific resolution was proposed; but the feeling of all present was expressed as decidedly favourable to the plan and character of the JOURNAL of the Association, as now conducted.

VOTE OF THANKS TO THE PRESIDENT.

Before separating for dinner, a vote of thanks was unanimously given to the President of the day, Dr. P. WILLIAMS, for his excellent address and conduct in the chair; which was acknowledged by him.

Letters were received from various members, regretting their inability to attend, one of which, from John Pughe, Esq., of Aberdovey, proposed that W. Owen, Esq., of Machynlleth, be elected a member of this Branch. This was unanimously agreed to.

THE DINNER

Took place at half-past three. The President, Dr. PETER WILLIAMS, was in the chair; and T. T. GRIFFITH, Esq., of Wrexham, occupied the vice-chair. There were also, in addition to all who attended the general meeting, the following gentlemen present as guests: the Rev. the Vicar of Holywell, and Rev. — Roberts, the Curate; Alexander Cope, Esq.; Samuel Williamson, Esq., of Holywell; and Mr. W. Wood, surgical instrument manufacturer, of Manchester.

After the various loyal toasts, the President gave the "health of the Bishop and Clergy," connecting with this his respected friend and neighbour, the Vicar of Holywell. They had then an opportunity of observing how diligently the ministers of religion discharged their duties.

The Rev. the VICAR returned thanks, stating that he was most happy to meet so many members of the medical profession on this occasion, as he considered that their two professions were inseparably united in benefiting humanity.

Mr. WILLIAMSON (solicitor), on his health being drank, returned thanks in a humorous and eloquent speech. He complained that the Vicar had omitted his (Mr. Williamson's) profession from the fraternal combination which he had mentioned. (Laughter.) He was, however, very happy to be amongst them, as he was deeply indebted to members of the medical profession for their skilful attention to himself and family.

Various other toasts and sentiments followed, and the greatest hilarity was maintained, until the time arrived for members to separate for their various homes.

WEST SOMERSET BRANCH:—ANNUAL MEETING.

The annual meeting was held at Clarke's Castle Hotel, Taunton, on Wednesday, June 29th. The following members were present: R. Burridge, M.D. (Taunton), President; W. E. Gillett, Esq. (Fairwater, near Taunton), President Elect; H. Alford, Esq. (Taunton); G. R. Burt, Esq. (Ilminster); W. Coates, Esq. (Wington); James Crang, Esq. (Timsbury); Alfred Haviland, Esq. (Bridgewater); W. M. Kelly, M.D. (Taunton); G. Kidgell, Esq. (Wellington); W. Land, M.D. (Taunton); R. Marchant, Esq. (North Curry); H. L. Nazer, Esq. (Wiveliscombe); W. C. Pyne, Esq. (Wellington); H. W. Randolph, Esq. (Milverton); G. F. Wills, Esq. (Crewkerne); and F. H. Woodforde, M.D. (Taunton), Treasurer and Secretary.

The minutes of the proceedings at the last annual meeting having been read, the report of the Local Council and the Treasurer's account were read and adopted.

OFFICERS AND PLACE OF MEETING FOR NEXT YEAR.

The following resolutions were adopted:—

"That the next annual meeting be held at Wellington; and that G. Kidgell, Esq., be the President Elect.

"That W. Reynolds, Esq., and G. Brock, M.D. (of Wellington), R. Marchant, Esq. (of North Curry), H. Alford, Esq., and W. M. Kelly, M.D. (of Taunton), and H. L. Nazer, Esq. (of Wiveliscombe), together with the President, President Elect, and the Secretary, form the Local Council for the ensuing year; and that Dr. Woodforde be requested to continue to act as Local Secretary and Treasurer."

VOTES OF THANKS TO RETIRING OFFICERS.

A unanimous vote of thanks was given to the retiring President, to the Council for the past year, and to the Secretary.

THE JOURNAL.

It was resolved unanimously,—

"That the improvement manifest in the ASSOCIATION JOURNAL, since it has been under the management of the present Editor, has the warm approval of the Members of this Branch."

THE DINNER.

After the meeting, the members present dined together. Among the toasts received with cordial applause were, success to the Association; the President of the Council; the General Secretary; the Editor of the Journal; Mr. Newnham, and the Benevolent Fund.

REPORTS OF THE ANNUAL MEETINGS OF THE BRANCHES: CAUSE OF THEIR DELAY EXPLAINED.

We have this week received Reports of the Proceedings of the BATH AND BRISTOL BRANCH, and of the LANCASHIRE AND CHESHIRE BRANCH, more than enough to fill one entire number. Being unwilling, without correspondence with the Secretaries, to make the necessary curtailments, we delay these Reports, though at great inconvenience; because, having provided a large sheet for this week's impression specially on their account, we are now obliged to fill it with matter destined for next week's number.

Carefully condensed Reports, appearing immediately after the Branch Meetings, are, we feel assured, those which are most read and appreciated. In future we shall arrange with the Secretaries in such a way as to prevent delay in publishing the reports.

EDITOR'S LETTER BOX.

EXCLUSION OF THE REPORTER OF THE "NORTH WALES CHRONICLE" FROM THE MEETING OF THE NORTH WALES BRANCH.

LETTER FROM JOHN LLOYD, Esq., TO THE EDITOR.

SIR,—In reference to the unanimous resolution of excluding a reporter from the Meeting of the North Wales Branch of the Provincial Association, allow me to give a more complete explanation of the circumstances which led to it, than, I believe, can be inserted in the Report of the Meeting. Nothing could exceed my regret at finding myself compelled thus to occupy the time which would have been more usefully devoted to other objects. But I confidently appeal to our fellow-associates, and ask them whether any other course could have been pursued?

In October last, I was desired to visit, in consultation, a sub-officer belonging to the extensive harbour works at Holyhead, who was a patient of Mr. Duncan, the surgeon to the works. I found Mr. Duncan exceedingly anxious about him, as the most unprofessional attempts (he said) were being made to interfere in the case, by a person who, he had every reason to believe, had not long settled in the town, with the intention of supplanting him in his office as surgeon to the works. He also bitterly complained that this interference, systematically carried on against him, was backed by appeals to the ignorance and prejudices of the workmen, with which he was unable to contend, from his imperfect knowledge of the Welsh language, and other causes.

To the patient in question, however, we directed our best attention, and had the pleasure of seeing him recovering from a severe attack of acute dysentery, chiefly under the influence of anti-phlogistic and mercurial treatment. Mr. Duncan, in a few days, pronounced him convalescent. This good result appeared to be too much for the feelings of the interfering doctor and his friends, and the patient was, almost *vi et armis*, withdrawn from under Mr. Duncan's care. He immediately became worse, and died in a very short time.

Under these disagreeable circumstances, Mr. Duncan consulted two highly respectable practitioners in this island (not members of the Association), who strongly advised him to have an inquest held. This was accordingly done; and Mr. Duncan, his assistant, and myself, attended. I took careful notes of the proceedings, which will at any time be at the service of the Association. At the inquest, there also attended Mr. T. Richards, a surgeon, of Bangor, who had seen nothing of the case, but who appeared to be present in order to defend the party whose conduct was the subject of inquiry. He asked me a simple question, calculated to lead to an answer favourable to his friend: this, however, I declined answering on oath, as it was of a speculative character, and did not bear directly on the facts of the case. In return, I asked Mr. Richards how he could give an opinion on a case which he had never seen? To this question he did not give a direct answer.

This short and simple conversation being all that passed between us, the editor of the Bangor newspaper (*North Wales Chronicle*) published a statement that Mr. Richards had made a violent attack upon me! This, however, formed only a part of a running fire of paragraphs and letters for weeks after the inquest, containing the grossest abuse and misrepresentation of Mr. Duncan and myself. To Mr. Duncan, these misrepresentations were of the most serious consequence, as, in conjunction with other equally unjustifiable proceedings, they were endangering his situation.

We both immediately wrote a short contradiction to the first statement which appeared; and this was allowed to appear in the paper. Afterwards, however, a great change appeared to take place in the "freedom of the press"; that "palladium of British liberty", etc. A violent agitation was excited against Mr. Duncan, and no doubt assisted greatly by this string of newspaper paragraphs. As these were seriously calculated to damage the official position of Mr. Duncan, I drew up for publication a careful statement, correcting many of the misrepresentations, and certainly commenting in severe terms upon the disreputable and truculent proceedings of which we had such just cause to complain. A copy of this document will be forwarded to you. Its publication in the newspaper referred to was promised us; it was then said to be too long; then it was too severe, and I was modestly asked to draw up a very mild, moderate, civil letter. I declined this very mild offer; and requested that if not all the

paper, at least a sufficient portion of it should be published, to form a reply to the misstatements. I also mentioned that I had been casually told by some legal friends that the paragraphs in the newspaper were *libellous*.

In the mean time, the storm against Mr. Duncan continuing to rage, he went personally to the editor, to ask him to publish the defensive statement. This was again refused. He therefore directed that it should be published as an advertisement in the *Carnarvon Herald*. What follows? The editor of the Bangor paper declares with the coarsest abuse that he will not publish any part of the statement, and defies me to go to law with him.

Now mark the consequence. All this combination of wickedness and impudence had at last the intended effect of acting upon the prejudices of the workmen at the Holyhead works, and Mr. Duncan, against whom no charge whatever had been preferred, was deprived of part of the emoluments of his situation, among scenes of violence, which would be a disgrace to a Tipperary mob. I am sorry to add that he has since resigned in disgust, and has left the place.

From this eventful story, your readers will see the justice of the proceeding, by which a representative of a press which had thus acted against two members of the profession, was unceremoniously ejected from the meeting of the North Wales Branch of the Association at Holywell.

I am, etc.,

J. LLOYD.

P.S.—I beg to direct your particular attention to the "elegant extract" in which the editor and proprietor of the Bangor paper notices the act of justice which has just been dealt to him. He appears to be anything but "serene", as he calls it; for, after venting his indignation upon the secretaries and the members generally, he (to use his own refined phraseology) "spits his venom" abundantly on my humble self. Without having been present or represented, he says that my statement at the meeting was false. The simple fact of my reading and calling attention to the fourth fundamental Rule of the Association, "that we are to maintain the honour and dignity of the profession," he says, was "a deliberate misrepresentation of our bye-laws"; and, speaking of a body of men who enjoy the confidence of the public, he hypocritically affects to tremble for the safety of those who are occasionally obliged to submit themselves to their care". And this is from an adventurer who has been settled in this country only a few years!

Llangefni, Anglesey, June 1853.

NEWS AND TOPICS OF THE DAY.

COURT OF QUEEN'S BENCH, JUNE 22.

FENNELL v. ADAMS* FOR SLANDER.

This was an action to recover damages for slanderous words alleged to have been uttered by the defendant, prejudicial to the professional character of the plaintiff.

The defendant pleaded "Not Guilty", and "justification".

Mr. M. Chambers, Q.C., Mr. Serjeant Wilkins, and Mr. Petersdorff, appeared for the plaintiff. The Attorney-General (Cockburn), Mr. Bramwell, Q.C., and Mr. Hall, were for the defence.

Mr. Chambers thus stated the case. The plaintiff is a surgeon at Wimbledon, and is medical officer of an institution there, called "The Maternal Society", of which the wife of the Rev. Mr. Adams, the defendant, is the treasurer. The charge made against the plaintiff by the defendant was calculated to affect seriously his professional reputation. The words complained of were to the effect, that the plaintiff had, in many cases, been very negligent in his attendance upon various females when in labour, and that several children had been, consequently, strangled in the birth.

Mr. Edward Fennell, the plaintiff, deposed that he is a surgeon residing at Wimbledon. In 1834 he purchased Dr. Wright's practice at Wimbledon, and paid £1000 for it. He was subsequently appointed to the Kingston Union, and to "the Wimbledon Maternal Society". In 1849 he received a letter from the Hon. Mrs. Adams, treasurer of the Maternal Society, and wife of the defendant, who is curate of Wimbledon. The letter contained general complaints, charging him (plaintiff) with neglect

of the female patients, but not naming any particular case. He called on Mrs. Adams in consequence, when she mentioned the case of Mrs. Gregory, wife of the coachman of Mr. Lefevre. He (plaintiff) attended her in 1848 or 1849. She had puerperal fever. He consulted with Mr. Parrott as to the treatment. She sank under the complaint. Mr. Lefevre expressed his satisfaction with the treatment. There had been 385 cases of midwifery under his (plaintiff's) charge, this was the only patient he had lost. In the case of Mrs. Elsley, Mrs. Adams refused to pay him his fee of half-a-guinea. He wrote to her for an explanation, and received a letter in reply, which stated, that, according to the regulations of the institution, the surgeon was not entitled to his fee unless he was present at the birth. He had attended Mrs. Elsley, who was the wife of a labourer, in three confinements, and on the occasion in question, Mrs. Riley was her nurse. He went to Mrs. Elsley immediately when he was called. He was at the time in attendance on a child named Roy, who was severely ill. When he arrived at Mrs. Elsley's he remained an hour in attendance, and finding the case was not pressing, he left, and went to see the child Roy, whose residence was within sight of Elsley's house. He (plaintiff) left word where he was going, and returned in twenty-five minutes to Mr. Elsley's. He then found the child born, and did what was necessary. There was a nurse and a midwife there at the time. The patient did well. He issued a circular, in answer to the injurious rumours which had been circulated regarding him, in which he stated that it had never occurred to him to have a child "strangled in its birth". Plaintiff subsequently called to see Mr. Adams but was informed by Mrs. Adams that he did not wish to be mixed up in the case.

Plaintiff, in cross-examination, deposed that he had no recollection of the nurse at Elsley's having said to him, when he was leaving: "I hope you are not going to leave me, as you did the last time?" When he returned to Elsley's, he had only to remove the placenta. He did not hear Mrs. Elsley make any declaration, and he asked several women whether there was any truth in the statement; and he subsequently drew up an official declaration, according to their statements, for them to sign. He attended Caroline Chester in two confinements; but could not recollect that he was present at the first of the births. At the second birth he did not remove the placenta. He was at the time in attendance upon another patient, who had a prior claim upon him, and he left to attend her before he removed the placenta. The woman might have said, upon his leaving: "Who shall we get?" and he might have said to her, "Who you can." When he returned, the placenta was still adhering. They called him up the next morning, at half-past five o'clock, and told him the woman was suffering, and asked him to give something to relieve her. He gave something, and called about nine o'clock, and removed the placenta. The plaintiff was then, in continuation of the cross-examination, questioned as to his attendance on Ann Dossett, Julia Rapley, Sarah Nicholls, Elizabeth Phipps, Mrs. Finch (who was twenty-five hours in labour), Mrs. Nicklebury, Mary Anne Frost, Mrs. Jordan (an Irishwoman), Mrs. Croach, and Mrs. Rapley. In those cases, the complaints principally were, that he (the plaintiff) was absent when the children were born, and a charge of neglect was imputed to him by the defendant's wife, and a further charge, that he (the plaintiff) was regardless, in such cases, of the claims and condition of the poor.

Mrs. Mary Savory, the late curate of Wimbledon, and others, gave testimony in favour of the plaintiff's professional and private character.

The Attorney-General addressed the jury for the defence, and submitted that any allusions made to the plaintiff by the defendant were made at a meeting of the lady subscribers of the Maternal Society, at which that gentleman presided as chairman, and that they were of the nature of a "privileged communication", and, as such, not actionable. He denied that the defendant had expressed any charge against the plaintiff about children strangled in their birth; but he admitted that he had accused him of gross neglect in the midwifery cases.

In support of the defence, Caroline Chester, Mary Freedy, Elizabeth Elsley, Maria Riley, Mary Stacey, Sarah Nicholls, Elizabeth Phipps, Mary Anne Elms, Mary Anne Hiddlebury, Mary Anne Frost, the Rev. Mr. Adams (the defendant), and Mrs. Holroyd, wife of Mr. Commissioner Holroyd, were called, and deposed to what passed at the meeting of lady subscribers to the Maternal Society. They had no recollection of anything having been said at that meeting by the defendant about strangled children.

The other female witnesses were principally those who had been confined by the plaintiff, and they spoke in favour of him.

* Sitings at Nisi Prius, at Westminster, before Lord Chief Justice Campbell, and a Special Jury.

which he had not been present at the moment of the birth of the child. It appeared, however, that he was in the neighbourhood, and came soon afterwards.

Dr. Arnott gave evidence that it was not good practice to leave the placenta in the uterus without placing the patient in experienced hands; but he stated that it was impossible for any medical man to foretell exactly the moment when a child would be delivered.

Dr. Murphy gave evidence of a similar character.

Mr. Montagu Chambers replied on the evidence, and urged upon the jury, that the communication casting imputations on the plaintiff was not a "privileged communication"; that it was a communication calculated to do the most serious injury to the plaintiff; and that he (the plaintiff) was therefore entitled to reparation in damages at their hands.

Lord Campbell summed up. The case was certainly a most painful one on one side and the other. The witnesses on both sides had conducted themselves in a most creditable manner. It did not appear that there had ever been a quarrel between the plaintiff and defendant, neither did it appear that the defendant had ever entertained ill-will to the plaintiff. Plaintiff, it appeared, had attended between four and five hundred midwifery cases in the course of his practice, and had never, he deposed, lost but one case, in which death resulted from puerperal fever. In the cases of the female witnesses who had been examined, there did not appear to be any serious evidence of neglect. He attended when called, and, perhaps, had other pressing cases when he left to go elsewhere. The questions for the consideration of the jury would be,—whether the communication of the defendant was a "privileged communication", and whether he had made out his pleas of "Not Guilty" and "justification". If they found that it was a "privileged communication", they would pronounce the defendant "Not Guilty", and the plaintiff would not be entitled to any damages; and, if they found that defendant had not made out his plea of "justification", they would then give a verdict for the plaintiff, which would entitle him to the costs of the trial, but not to damages.

The jury returned a verdict for the plaintiff, on the plea of "justification"; and for the defendant, on the ground that the communication was "a privileged communication", and, therefore, not a guilty one.

Lord Campbell: I am perfectly satisfied, gentlemen, with your verdict. I am happy to say, that by it both parties go out of Court with their characters reestablished.

MEDICAL BENEVOLENT COLLEGE.

The foundation stone of this institution, which is to be erected in the neighbourhood of Epsom, was laid on Wednesday last, the 6th instant, at 4, p.m. It had been announced that His Royal Highness Prince Albert would perform the ceremony; but, in consequence of His Royal Highness labouring under an attack of measles, the Right Hon. the Earl Manvers, President of the College, officiated. The absence of the Prince, and especially the cause, were the subjects of universal regret. The Lord Bishop of Winchester performed the religious portion of the ceremony; and appropriate psalms were sung by the parochial school children of Epsom. A large concourse of spectators were present, among whom were a goodly number of ladies. The band of the Royal Marines attended.

After the stone had been laid, a large portion of the company present adjourned to an adjoining tent, where a *déjeuner* had been provided. The Earl Manvers occupied the chair.

After the usual loyal toasts, coupled with expressions of regret at the cause of the absence of Prince Albert, had been drank, the following were proposed and duly responded to. "The Medical Benevolent College"; by the President. "John Probert, Esq., the Founder of the Medical Benevolent College"; by Henry Pownall, Esq. "The Ladies", who had so warmly supported the Institution; by Nathaniel Clifton, Esq. "The Earl Manvers"; by the Rev. Mr. Pocock. "The Bishop and Clergy of the Diocese"; by J. W. Freshfield, Esq., M.P. In reference to this toast, Mr. Probert stated, that in his applications to the Bishops, he had always met with a most cordial reception.

Mr. PROBERT stated, before the company separated, that he was not yet able to state the exact sum which had been collected on that day. It is believed, however, that the amount was not far short of £2000. He then read a list of donations received for the day, among which were the following: the Earl Manvers, £52; 10; B. E. Winthrop, Esq. (of Dover), £525; the inhabitants of Epsom, £130; the Croydon and Epsom Railway, £100; Dr. Forbes, £100; John Churchill, Esq., £100; Sir Charles M. Clark, £21; besides numerous donations of ten guineas and five guineas each.

MEDICAL STAFF OF THE BURMESE ARMY. "Here is an extract from Sir John Cheape's despatch:—'To Surgeon Andrews, 67th Native Infantry, and the medical department, I have to return my best thanks for the performance of their very arduous duties in the care of the sick and wounded; and to Assistant-Surgeon Murphy, officiating staff-surgeon to the division, in particular my special thanks are due; he was the senior medical officer until the arrival of the reinforcements from Rangoon, and all the arrangements made by him have been most perfect. On the 19th instant, the wounded men were attended to by him under a very heavy fire, and though wounded (I am happy to say very slightly), it did not deter him a moment from the zealous discharge of his duties; he has performed them throughout in the most unwearied and able manner, accompanying the men in the boats to the steamers, and seeing them carefully attended to, and disposed of. I consider the force fortunate indeed in having a medical officer of his talent and character in such trying circumstances, and I feel assured the Major-general will accord his approbation of the services of this officer.'

"Sir John Cheape is a scientific officer, being of the corps of engineers, and is therefore especially qualified to give an opinion of the merits of a scientific body. In the British army, officers of the Artillery and of the corps of Engineers are, by the habits of this country, altogether excluded from command, whether in peace or in war. In the Indian army, it is otherwise. Sir Geo. Pollock and Sir William Whish both held command of armies, although officers of Artillery; and Sir John Cheape, more remarkable still, is, as we have said, an officer of the highest scientific class, namely, an engineer. It has been observed, that, the more scientific an officer is, the more friendly does he prove to the military surgeon. Abercrombie and Moore were the intimate personal friends of Robert Jackson."—*Lancet*, July 2nd.

DON TOMAS DE CORRAL Y ONA. This eminent obstetric physician of Madrid has been appointed to attend the Queen of Spain during her pregnancy and confinement. Her Majesty is in the third month of her gestation. This appointment has deservedly given much satisfaction to the profession and the public in Madrid. Dr. Corral y Ona is the author of an excellent work on Homeopathy, entitled "*La Homeopatía, ó Farmacología Analogo-Infinitesimal, ante el Criterio y el Sentido Común*".

MEDICAL JOURNALS OF MADRID. The first number of a new medical journal, *La Crónica de los Hospitales*, has just appeared in Madrid. It is to be published on the 8th and 24th of each month, by Bailly-Baillière of the Calle del Príncipe. The other medical journals of Madrid are the *Boletín de Medicina, Cirugía, y Farmacia*, and *El Heraldo Médico*. We regularly receive the two last named weekly periodicals in exchange for the ASSOCIATION JOURNAL, and shall be glad to establish a similar reciprocity with the *Crónica*.

SALT. In the House of Commons, on Monday, the Marquis of Westminster, in presenting a petition from the inhabitants of the town and neighbourhood of Northwich, praying that English salt might be imported into all parts of British India upon the same terms and conditions as other goods and manufactures, said: If the advantage from opening the trade would be great to the commercial gentlemen of Lancashire and Cheshire, it must be much more so to the unfortunate Hindoo, who, during eight months of the year, lived entirely on rice, and, during the other four months, on any other vegetable matter he could obtain. Salt to the Hindoo was an absolute necessary of life, and it saved him from disease and death. Notwithstanding the importance of a sufficient and pure supply to the people of India, the policy pursued by the government of India had introduced a system of adulteration which was utterly incredible. It was well known that the impurities attaching themselves to salt amounted to about 13½ to 100 lbs; but, in the salt sold wholesale by the Company, the impurities increased to a much larger amount; and it had been estimated that, of the salt sold in retail, the adulteration was not less than one-half. From this cause, the salt sold to the natives was so distasteful to them, that, previous to using it, they were obliged to resort to a process of purification.

FEMALE PHYSICIANS. The Female Medical College of Pennsylvania will commence its next course of lectures on the 1st of October. Its Faculty consists of five male and two female Professors,—the latter regularly graduated physicians, as well as the former,—while the Demonstrator in Anatomy is also an able female physician.

MEDICAL REFORM.

[House of Commons, Monday, July 5th, 1853.]

Colonel DUNNE inquired what course the Government intended to take with respect to the introduction of a Bill for regulating the Medical Profession? He also wished to know whether certain regulations or bye-laws of the Pharmaceutical Society had been referred to the law-officers of the Crown?

Lord PALMERSTON hoped to be able to bring in a Bill, but probably not so much with the view of passing it this Session, as with the view of submitting its provisions to consideration. At the same time, he did not preclude himself from proposing it with the view of carrying it. With respect to the bye-laws of the Pharmaceutical Society, they were presented to him for approval. He sanctioned them, subject to any legal decision which might be come to in one of the articles, to which objection had been made as not being consistent with law. He would not take on himself to decide that point; neither did he think it expedient to refer it to the law-officers of the Crown.

LONDON MEDICAL REFORM COMMITTEE. We understand that a meeting of this body was held on Tuesday evening last, to consider the statement made by Lord Palmerston in the House of Commons on the previous evening. It was resolved, that the Committee should hold themselves prepared to act promptly, in case of any bill for medical reform being brought forward by the government; and, as little doubt was felt that the measure introduced would be the same as that which has already been so much discussed by the profession, it was determined that active assistance should be rendered to the government, to enable it to be passed into law.

ROYAL COLLEGE OF SURGEONS:—PASS LIST. MEMBERS admitted at the meeting of the Court of Examiners on the 24th June:—Slade Innes Baker, Hayford Warren, Oxfordshire; Joseph Barker, Durham; William Griggs, Little Easton, Dumfries; William Angelo Knaggs, Kensington; William Hitchin Pendlebury, Bolton, Lancashire; Henry Pratt, Montreal, Canada; Robert Bath Smart, Balsham, Cambridgeshire; Henry G. Sturkey, Fachwen Tregynon, Montgomeryshire; Harry Barrington Tuttielt, Ventnor, Isle of Wight.

APOTHECARIES' HALL:—PASS LIST. Thursday, June 23rd, 1853:—Fergus Armstrong, Appleby, Westmoreland; Edmund Chapman; William Kaylet Curtis, Harting, Petersfield; Horace Kersey Debenham, Norton, Suffolk; Christopher Deighton, Edinburgh; Joseph Ferguson Lindley, Stalybridge, Lancashire; William Robert Faun Marchant, North Curry, Somerset.

APPOINTMENTS.

[*An asterisk is prefixed to the names of Members of the Association.]

CLARKE, W. T., Esq., elected Surgeon to the Huddersfield Infirmary.

GREEN, Joseph Henry, Esq., F.R.S., appointed Consulting Surgeon to St. Thomas's Hospital.

*SOLLY, Samuel, Esq., F.R.S., elected Surgeon to St. Thomas's Hospital.

TATHAM, T. B., Esq., elected Surgeon to the Huddersfield Infirmary.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were Members of the Association.]

GRAVES, William Henry, Esq., Surgeon, at 40, Trinity Square, Tower Hill, aged 52, on June 27.

NICHOLL, W. K. L., M.D., formerly of Ryde, Isle of Wight, at 7, Upper Porchester Street, Hyde Park, aged 75, on June 23.

WETHERHEAD, George Hume, M.D., at Foot's Cray, Kent, aged 63, on June 22.

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London: or to the office of the Journal. Letters requiring immediate attention and revised proofs ought invariably to be sent to Putney.

ADVERTISEMENTS.

Just Published, Part I, with Engravings on Wood, Price 3s. 6d.

The Pathology of the Bronchio-

PULMONARY MUCOUS MEMBRANE. By C. BLACK, M.D., Bachelor of Medicine, and formerly Medical Scholar in Physiology and Comparative Anatomy in the University of London; Fellow of the Royal College of Surgeons of England, etc.

London: SIMPKIN, MARSHALL, & Co. Edinburgh: SUTHERLAND & KNOX.

New Volume of Braithwaite's Retro-

SPECT OF MEDICINE. JANUARY TO JUNE, 1856. Just published, price 6s., the 27th Volume of this Work, giving a careful Analysis of the most Practical Papers, Lectures, and Transactions of Societies, published in all the Medical Journals within the last Six Months. Appended to which is an Alphabetical List of Diseases; with the most recent Suggestions of Treatment. Edited by W. BRAITHWAITE, Lecturer on Obstetric Medicine in the Leeds School of Medicine, etc.

N.B. A limited number of Sets of the above work, Vols. 1 to 25, have been made up, and are offered at the reduced price of £4, in cloth. Separate vols. at the original prices, viz. vols. 1 to 3, at 4s. 6d. each; Vols. 4 to 11, at 5s. 6d. each; Vols. 12 to 27, at 6s. each.

London: SIMPKIN, MARSHALL, and Co.

On Certain Diseases of the Skin

generally pronounced intractable, illustrated by upwards of Forty Cases. By THOMAS HUNT, F.R.C.S., Surgeon to the Western Dispensary for Diseases of the Skin.

OPINIONS OF THE MEDICAL PRESS.

"Mr. Hunt has transferred these diseases *en masse* from the category of the *in-curable* to that of the *curable* maladies; and we venture to say that there are few English practitioners who have failed to profit by these important investigations."—*Lancet*.

"The directions given by Mr. Hunt are very different from those generally laid down by preceding writers. His observations are highly judicious, and fraught with instruction and benefit; the ultimate results of which indeed can scarcely be calculated."—*Provincial Medical and Surgical Journal*.

"No one can rise from the perusal of the work without some insight into the cause of the frequent failure of the treatment of affections of the skin. Nor ought we to omit bestowing on Mr. Hunt that praise which is due for having abstained, in a small work on skin diseases, from all quackery and self-laudation."—*Medical Times*.

"The method of treating chronic skin diseases upon the plan so ably recommended and illustrated by our talented associate, Mr. Hunt, has been tried in America with considerable success."—*Provincial Medical and Surgical Journal*.

Also, by the same Author, 1s., stitched,

On SYPHILITIC ERUPTIONS; with

especial reference to the use of Mercury.

"We regard Mr. Hunt's views to be of considerable importance."—*Ranking's Abstract*.

London: JOHN CHURCHILL, Princes Street, Soho.

Marischal College and University,

ABERDEEN—Besides the ordinary Examination Terms, (in April and October,) there will this year be a third, in the last week of July, to meet the case of Candidates for the Assistant-Surgeoncy H.E.I.C.S. offered by Col. Sykes to the best competitor among the students who have completed their academical course at King's or Marischal College; and for the Assistant-Surgeoncy in Her Majesty's Service, offered for competition to the students of Marischal College, by the Director-General of the Army Medical Department.

CASES IN WHICH MEDICAL PRACTITIONERS MAY BE ADMITTED, WITHOUT RESIDENCE, TO EXAMINATION FOR MEDICAL DEGREES.

Practitioners may be admitted, without residence, to Examination for the Degree of M.B., who have held a Diploma or a Licence in Medicine or in Surgery for at least five years, and who produce satisfactory evidence of good moral character, and of having been engaged in practice during that period.

Practitioners may be admitted, without residence, to Examination for the Degree of M.D., who have held a Diploma or a Licence in Medicine or in Surgery for at least ten years, and who produce satisfactory evidence of good moral character, and of having been engaged in practice during that period.

Practitioners who have held for at least three years the Degree of M.B., obtained without residence, may receive the Degree of M.D., upon producing satisfactory evidence of good moral character, and of having been engaged in practice during their possession of the inferior Degree.

YORK COUNTY HOSPITAL.

A Special Court of Trustees and

GOVERNORS of this Charity will be held at the Hospital, on FRIDAY, the 22nd of JULY next, at ONE o'Clock in the Afternoon, for the Election of a HOUSE SURGEON.

He must be an Unmarried Man, between the Ages of Thirty and Forty-five Years. He will have to reside in the Hospital, and to undertake the whole internal management of it under the House Committee. The Salary is £200 a year, with Board and Lodging.

Candidates are requested to send Testimonials to my Office One Week, at least, before the day of election.

JOHN HUGHES, Secretary.

York, June 9, 1855.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XXVIII.

LONDON: FRIDAY EVENING, JULY 15, 1853.

NEW SERIES.

GENTLEMEN WISHING TO JOIN THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION ARE REQUESTED TO APPLY TO THE GENERAL SECRETARY, TO THE BRANCH SECRETARIES, OR TO THE EDITOR OF THE JOURNAL. The Annual Subscription is One Guinea. The Subscription runs from January to January; and members now joining will receive the Numbers of the JOURNAL from the commencement of the year. Members receive the JOURNAL free by post.

LETTERS TO THE EDITOR ON THE SUNDAY QUESTION.

On the 24th of June, we introduced to the notice of our readers the petition of six hundred and forty physicians, surgeons, and general practitioners in London, praying Parliament not to alter the existing law so as to allow the Sydenham Crystal Palace to be opened on Sundays for the gain of its proprietors. We, at the same time, recognised the political importance of the right decision of the question whether Sunday should be a day of rest, or a day of pleasure. We advocated the right of the toil-worn population to a weekly holiday, for their secular recreation, at home or abroad; and we exposed, as the offspring of mistaken philanthropy, the schemes of those estimable men, who are now wishing to destroy the present character of Sunday, and to make it a grand legalised day of extradomal pleasuring. On the low grounds of political expediency, we showed that the prosperity and patriotism of our population could not be maintained, unless one day in seven was generally observed as a domestic day.

On the 1st of July, in reply to Dr. Forbes, we carried our argument a little farther; and, having called attention to the fact that Sunday Slavery necessitate the addition of weekly Sunday Slavery to six days' hard labour, we remarked:—

"Can words be too hard, whereby to designate this cruel tyranny of the many over the few? . . . If man really be born to immortality, the establishment of so strict a quarantine between the creature and the Creator is a crime of magnitude too enormous for words to compass."

We have thought it necessary thus briefly to repeat the grounds upon which we defended a weekly day of rest from labour, because, after perusing the letters of Dr. Markham and Mr. E. Sheppard, it occurred to us that our readers might begin to fancy that the views assailed by these gentlemen were the views which we had advanced and advocated. This is wide of the truth. We never described religion as an irksome duty, as a sort of necessary, yet dreary penance; nor did we ever seek to identify prayer with the "technicalities" of breviary and bead, of liturgy or litany. On the contrary, the whole tenor of our writing proceeded on the assumption that religious duties are refreshing both to the body and to the mind, and that what Dr. Forbes so happily calls *technical* religion, is not religion at all. We were not

oblivious of the fact, that the same Divine Being who commanded the Jews to "remember the Sabbath day to keep it holy", and who likewise instituted many ceremonial observances, taught his people carefully to distinguish between forms of religion and religion itself. In the first chapter of Isaiah, we remembered that these words are written:—

"Bring no more vain oblations; incense is an abomination unto me: the new moons and Sabbaths, the calling of assemblies, I cannot away with: it is iniquity, even the solemn meeting.

"Wash you, make you clean; put away the evil of your doings from before mine eyes: cease to do evil:

"Learn to do well: seek judgment, relieve the oppressed, judge the fatherless, plead for the widow.

"Come now, let us reason together, saith the Lord: though your sins be as scarlet, they shall be as white as snow; though they be red like crimson, they shall be as wool.

"If ye be willing and obedient, ye shall eat the fruit of the land."

The letters of Dr. Markham and of Mr. E. Sheppard in no way touch our arguments, and are calculated to import into the controversy a great deal of irrelevant materials. As for the letter of our respected friend, who adopts as his signature a reference to Isaiah, we feel perplexed beyond measure. If words have any meaning, the beautiful passage to which he refers is an overwhelming answer to every argument in favour of Sabbath pleasuring, provided that we consent to try the question by the Bible. The only three letters which we have received for publication, in opposition to our views, are those to which we have now referred, and which will be found in subsequent pages of this number. We invite our readers to peruse them, in connexion with our previous articles, and decide between their authors and ourselves.

From upwards of fifty letters which we have received in support of our own views, we print as many as space will allow. The different points from which different accomplished minds contemplate the subject, and yet reach the same conclusion, cannot fail to interest and to edify a numerous portion of the members of the Association, though the opinions expressed may not always command assent. It is with inexpressible pleasure that we read and publish such letters as that of Professor Miller; yet we must, as medical journalists, confine the discussion within the limits which we have already indicated, and rest satisfied by vindicating the present law and custom of this nation in reference to Sunday, on the grounds of—

I. POLITICAL EXPEDIENCY;

II. THE CRIMINALITY OF ESTABLISHING A QUARANTINE BETWEEN THE CREATOR AND ANY NUMBER OF HIS CREATURES; and

III. THE PHYSICAL AND SANITARY REQUIREMENTS OF THE HUMAN RACE.

For some weeks to come, we cannot possibly return to this subject; but we may revert to it upon some suitable occasion. In the mean time, we commend to

general attention the letters published in this day's number, as they afford a cheering and convincing proof that the soundest principles of Christian ethics deeply pervade the profession of Medicine.

THE BRANCH MEETINGS.

THE length of our reports of the Branch Meetings leaves us very little space this week for leading articles, and obliges us to postpone much matter which we had prepared in the departments of Bibliographical Notices and Periscopic Review. The great interest and value of the reports, however, will make them generally acceptable to members. If it were possible to prevent so many Branch meetings happening simultaneously, the result would be felt as a general benefit to the ASSOCIATION; as it would enable the proceedings of the Branch meetings to be promptly reported, without disturbing the usual plan of giving a varied character to the contents of each number. We are very far from thinking that our Branch meetings are too frequent: nay, we are every day becoming more and more convinced that the best method of increasing the usefulness and augmenting the power of the Association is for district meetings to be multiplied, and for members to feel that attendance upon them is a duty which they owe to themselves and to their profession. Formal business assemblies are not always required; and a meeting may often be productive of great present and prospective advantages, although its proceedings claim but a small amount of space in these columns.

The remarks upon the importance of more frequent meetings made by the President of the Suffolk Branch particularly arrested our attention; and we think that resolutions in accordance with the spirit of his speech might well be acted upon throughout the Association. If the medical profession ever attains to its legitimate social status and political power, it will be by its members being better organised, and meeting more frequently with each other, not merely for scientific improvement, but for the purposes of brotherly intercourse, and of discussing the medico-political and professional topics of the day. Then, and not till then, will it be possible to form any conception of the immense and ever augmenting benefits bestowed upon the medical profession by Sir Charles Hastings, when he founded the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

ORIGINAL COMMUNICATIONS.

IMPACTION OF THE RECTUM FROM UNGROUND WHEAT.

By T. INMAN, M.D.

CASE. A. B., aged 60, was admitted into the Northern Hospital, July 5. He was a poor Irish emigrant, and seemed too ill to give any account of himself. The sickening odour which proceeded from his breath and body prevented a prolonged examination of his person. He was, on his admission, making constant but ineffectual attempts to vomit, and told us that he was purged. Further inquiry indicated that "he was not purged at all, but that every thing came up the other way". The pulse was very weak, and the man seemed almost in a dying state. The symptoms being those of strangulation of the bowel, I examined the groins, and found that there was a double scrotal hernia. There was, however, no tenderness on pressure, nor anything to show that the mischief was there. The first object was to gain as accurate information as possible respecting the condition of the bowels; whether there was really constipation, or not. Castor-oil was ordered, and his strength was supported by wine.

The oil operated freely, producing copious watery evacuations, which were seen by the house-surgeon. On my next visit, the man was evidently worse; and he then informed me that ten days ago they had given him wheat instead of rice, and that "nothing had passed through him since". Having heard of a similar case, where peas had been eaten too freely, I directed an enema to be administered, to ascertain whether there was any lodgment in the rectum. The man, however, died before it could be administered, twenty-four hours after admission. He had hiccough before death, and an intensely sickening breath, which had something of a spirituous odour; at least, after trying to think what it reminded me of, this came the nearest to it. On making a post mortem examination, the same odour was very strong about the bowels. The bowels were much distended with flatus; the ileum was, in some parts, perfectly contracted, in others distended. The whole of the intestines were gorged with blood, and congested; but there was no effusion of lymph. The inguinal canals were very large, and quite clear from any part of the gut. The colon was greatly distended with flatus. The sigmoid flexure and the rectum were stuffed full of wheat: a great part of this had been chewed, and consisted of the husk alone; the rest consisted of grains, swelled and distended by the absorption of fluid,—about a quart was collected in all. It had a smell similar to that exhaled by the breath; but I cannot say that there were marks of fermentation.

REMARKS. Had this man been seen earlier, or had he been able to give us a clear history of his case on admission, I think it exceedingly probable that his life might have been spared; for an examination of the rectum, or the effects of an enema, would have made the case clear. As it was, the absence of clear information, and the necessity for procuring it before proceeding to act, rendered delay necessary,—and that delay was fatal. To give an idea of the conflicting nature of the history I received, I may mention that the man said he was never purged. The patients in the wards said he was constantly going to the stool; the nurse, that he passed liquid motions; and that the house-surgeon, who saw them afterwards, imagined the man had diarrhoea.

Liverpool, July 1853.

THE LOCAL TREATMENT OF CARBUNCLE AND FURUNCLE.

By RICHARD FLINT, Consulting Surgeon to the Stockport Infirmary.

It is the distinguished triumph of modern surgery to be able to relieve and cure many of the ailments within its province, by methods less painful and protracted, and more certain than were formerly employed. The diseases at the head of this short notice cannot, I fear, be classed under this category. I was only aware, in an inquiry into the recent epidemic which has so severely and widely extended its visitations as to remind us of the "Plague of boils in Egypt", that the old treatment in the great hospitals of the country and with the most eminent surgeons, remained unchanged, and was holding its inglorious sway, from the comfortless and hopeless poultice, to the deep crucial incision of the scalpel; yet having at least the merit of being as impartially and equally inflicted on a professional brother, as on the laity or public at large. This practice by fomentations and poultices of every kind and description, soothing and stimulating, with ointments and plaisters of a like quality, has, from time immemorial, been the common inheritance of household and professional surgery. And it has often been pursued with the most indefatigable zeal and perseverance, without relief to pain and suffering, which have been in many cases intolerable, and with scarcely discernible progress in the condition of the diseased parts; until both surgeon and patient, full of disappointment and vexation, have looked to the knife as their only remaining alternative—if haply it be in time—to arrest or prevent the tendency to direful symptoms which too frequently result from the larger carbuncle or sloughing boil.

It is not my design here to investigate or trace out with Dr. Laycock* the laws which govern the invasion of these exanthemata: yet I confess there seems full ground, from the facts adduced, for his ingenious and philosophical speculations as to their epizootic origin. Nor is it my intention to enter with Dupuytren† into those minute proximate changes which are effected in the tissues involved in these affections. My only purpose is to give an account of a local method of management—simple and obvious in itself—which forced itself upon my attention more than twenty years ago, and which has been followed in my hands, and I trust will be found equally so in the hands of others, by such invariable and uniform success, as I think may almost entitle it to the term of “specific”. The advantage is, that it is adapted to every condition of the system and every stage of the morbid action, which it seems at once to check and control: and whether the disease be of the more acute, subacute, or chronic form, or the habit plethoric, asthenic, or cachectic, I find the application equally appropriate and efficient.

But it is understood that a suitable constitutional treatment is conjoined with the local dressing. It has long been my conviction that carbuncle and boil generally arise from the same or similar conditions of the blood, as they often exist at the same time in the same individual, the boil not unfrequently running into a carbuncle, and the structures involved being the same. The latter would in general appear to be only a more extended or advanced stage of the processes of the former; but with this difference, that while the primary actions of a boil are in the cutaneous tissue, with an acuminated phlyctæna or pustule, and the subjacent membrane is affected secondarily, in a carbuncle the order of attack is in the inverse direction.

Considering these morbid actions as manifesting want of power in the vascular system of the parts affected, I sought for an application that would, if possible, assist or increase it, and at the same time not interfere with the natural excretions from the skin. This I thought I saw in the common lead or litharge plaster, spread on the white leather of the shops. The former, if correctly prepared, will answer fully the object intended; and the latter ought to be well dressed, having no hard or harsh parts in what is selected for use. There is in lead plaster, besides its unirritating quality, a valuable property, which seems to have been often overlooked or forgotten—that of promoting or inducing perspiratory exhalation from the skin. Every surgeon must occasionally have noticed that, where the common lead fascia (containing no resin) has been allowed to remain on any part of the trunk or limbs for weeks, when it is removed there will be seen a considerable quantity of perspiratory fluid which has been pent up, showing no other consequences than a little soddening of the skin upon which it has been so long confined. For this reason, I always prefer using the plaster without any admixture or combination; and, if fresh, it has every requisite adhesive property. To this peculiar effect on the cutaneous exhalants, I attribute much of its beneficial influence in the more acute boil or carbuncle. It must, however, be allowed, that in the extremely acute forms of this disease, the most soothing applications to the surface of the skin are indispensable, and that fomentations and poultices, for twenty-four hours or longer, may be quite necessary. But I would say that as soon as the plaster can be borne, it ought to be applied without delay. It is likewise to be remembered that there are idiosyncrasies where a plaster, entirely unirritating under ordinary circumstances, cannot be endured, from the cutaneous irritation and excitement which follow its use. This, of course, is to be regarded as an exception to a rule.

The mode of application is the following. After spreading the plaster in the ordinary manner, it is to be cut in dimensions according to the size of the carbuncle or boil to be dressed; carefully observing that it is large enough to include from half-an-inch to two or three inches of the sur-

face around the tumour. Where this is large and deep, as in a carbuncle from four to six or eight inches in diameter, the circumference to be embraced should be proportionately large; and the leather, in such a case, should be chosen soft and strong, in order to obtain an amount of adhesive mechanical support to the surrounding and subjacent parts, so as to enable them to originate and establish a new action. It must be well remembered that it is not enough, in any of these dressings, to cut the plaster the exact size only of the tumour. It is expected that some of the surrounding surface should be taken in also.

In twenty-four hours after dressing, a favourable change in the appearance of the parts is generally discernible; and—what will be allowed to be a highly important result, in those cases where the local irritation is fast inducing a state of cerebro-spinal distress and lesion, likely soon to end in coma and death—it will often, in a less period of time, afford a mitigation of suffering which comes upon the patient like a charm, and restores him the rest and sleep to which he had long been a stranger. If the tumour be prominent or pointing in any part, a crucial incision is to be cut in the plaster, and placed directly over it, that the discharge may have free egress: and should there be at first no suppuration, this mode of dressing quickly promotes it, and assists the living parts to detach and throw off, at the least possible loss, the sloughy cellular membrane. If the tumour is not disposed to slough or suppurate, the application decidedly hastens the resolution or absorption of the effused matter.

In a boil, the dressing is precisely the same as in a carbuncle; taking care that the plaster has sufficient hold of the tissues around—perhaps from half-an-inch to an inch. In a few hours, the acute pain and suffering of the patient, which had unceasingly disturbed his rest and comfort, become greatly mitigated, and soon afterwards wholly removed; and the improvement in the condition of the parts is strikingly apparent on every renewal of the plaster. The little trouble and inconvenience of this method, both to patient and surgeon, strongly contrast with the inconvenience, wearisome labour, and attention required by the old plan; and whilst the latter necessarily confines the patient, even in minor cases, to the house, in bed, or on couch, the former will often be little or no restraint on his usual avocations.

It is requisite that the plaster be changed more or less frequently, according to the extent of discharge or slough; but the longer the interval, the more desirable, as the less the parts are disturbed the better. If there be much discharge or slough, soiling the cut edges of the plaster, it may be changed once a day; if there be little, every third or fourth day will be sufficient; but the linen pledgets and bandage adjusted over the plaster, and absorbing the discharge as it exudes, may be replaced frequently. In general, no other dressing is required to the end of the treatment. The plaster must be reduced in its dimensions as the tumour lessens in size, whether it be by suppuration, slough, or absorption. In some instances, towards the close, simple or calamine cerate may be desirable. The solution of the nitrate of silver, of the strength of 3i. to 3i., will also be found of great value as a cicatrizer; for I concur with my friend Mr. Higginbottom that, besides other valuable properties, which he has so ably advocated, there is no agent in the surgery so useful for promoting healthy cicatrization or removing excoriations as lunar caustic. It likewise excels all other means in giving increased vigour and strength to a new cicatrix.

From what I have seen of this method of treatment in a number of patients during the last several years, and from the speedy relief or total removal of pain and distress in the worst cases, and in bad temperaments, I have looked upon it as of great value, if attentively carried out; for I am persuaded that it will render recourse either to the knife, to caustic remedies, or any of the other more severe measures of our art, unnecessary. Should, however, the choice of the surgeon and patient lead them to the latter alternative, I would strongly enforce that, whether it be the knife, or the caustic, it be always used at an earlier stage of the disease

* Medical Times, March 8th, 1851.

† Clinique Chirurgicale, tome iv, p. 210.

than is yet commonly practised; as this, like the early free incision in diffusive inflammation of the cellular membrane, will prevent the destructive ravages of tissue, as well as the fatal constitutional symptoms which follow the unchecked and protracted course of the disease.

As an illustration of the effects of the dressing here described, I will relate two or three cases.

CASE I. About the end of last year, a gentleman, aged 68, was convalescent after a dangerous attack of bronchitis, which had confined him to bed and to his room for six weeks. At the end of this time, he was regaining the healthy powers of his system; his digestive organs were vigorous; the strength which he had lost was gradually returning; and my attendance upon him had so far declined that he only required a call every third or fourth day, in order to watch his progress. On one of these occasions, in answer to an inquiry how he had been, he said, smilingly, that he was going on very well, but had lost sleep from a troublesome boil; yet, entertaining a belief in the humoral doctrine, that boils had a healthy indication, he supposed that he must wait patiently until it passed away. His countenance, neither on this nor the next visit, denoted any injurious effects from pain or irritation; but, on calling a third time, I discovered that he was losing the ground which he had gained; his appetite had greatly lessened; and he confessed that he had had little or no sleep for a week, having found no relief in any position from the pain he suffered, although his daughter had very assiduously fomented and poulticed the parts affected. On a closer examination, it was evident that his general powers were declining; but, conceiving that his indisposition only arose from a boil, he evinced no anxiety or wish for me to see it. I requested immediately, however, to look at it; and found a true carbuncle, extending across the loins, and measuring five inches by eight; it formed a broad tumour, with great induration, and was, from interstitial deposit, one and a half or two inches in depth at its centre, decreasing to the circumference. There were two ulcerated points on its surface, showing sloughy cellular membrane within. The nature of the case was clearly apparent; and indeed it might be regarded as one of the later cases of the epidemic which had prevailed for many months in this neighbourhood. The poultices were removed, and the plaster applied according to the plan described; and, though at first it felt, as he said, rather tight and close, his pain was soon relieved; he had a better night than for a week before, being able to turn himself round more readily (he had before spoken of the extreme difficulty of moving, from the severity of pain during the use of poultices). Every succeeding day and night were followed by improvement. It was surprising how little of the cellular membrane sloughed, and how gentle and moderate the suppuration was, considering the formidable character of the tumour. The discharge exuded and escaped regularly through the opening in the plaster, and was absorbed by the pledgets over it; and every renewal of the dressing gave ease and comfort to him. His appetite and general strength were soon regained; and he had not afterwards a single unfavourable symptom. He is at the present time in his usual health, or even better.

In this case, there was no other dressing used but the plaster, reduced in size as the tumour diminished; and the solution of nitrate of silver, to remove a slight excoriation, and to quicken the healing of the two points where the shreds of cellular membrane had escaped. Towards the close of this treatment, a common boil made its appearance within a few inches of the carbuncle; it was treated with a plaster, and its progress at once checked.

CASE II. A few months ago, an old gentleman, aged 75, always previously of good health and invariable appetite, was seized with two large carbuncles, which he called boils, one on the lower end of each scapula. His pain and suffering were so great for ten days and nights, that, not being able to rest in bed, he spent most of the time in his parlour, partly on a couch, and partly walking about, but refusing any surgical assistance. The poultice system had

been persevered in from day to day, without the slightest abatement of his distress; and he at last consented, at the end of the period above named, that I should see him. I found his appearance very much altered; his strength and appetite were wholly gone; and he had every symptom of a man fast sinking into death. On examining his back, I found one carbuncle, four inches by four, and another, four inches by six. Each had inflammatory redness, of a low character, on the surface. One showed a point of ulceration, with sloughy cellular membrane within; the other had two points, with a like appearance. I had no expectation of restoring the patient from his prostrate and exhausted condition, as the continuance and severity of pain had produced such an extent of cerebro-spinal lesion as to deprive the digestive organs of all power to take the ingesta requisite for his support. He begged only for relief from his unremitting distress. A plaster was applied to each of the tumours, in the manner described; and, although the vital powers could not be successfully rallied, the effect, upon the diseased parts, of the plasters, which were renewed every third day, was very surprising, inducing a regular suppuration and detachment of slough, with a manifest increase of comfort and ease to the patient; and his life was prolonged for a fortnight.

CASE III. The third case was that of a gentleman of middle age, who had been poulticing a sloughing boil, about an inch in diameter at the base, which had for several weeks occupied the space between the metacarpal bone of the thumb and fore-finger. He had excellent domestic nursing, but the parts made no progress towards healing. He suffered great constitutional irritation, with inflammation of the absorbents of the forearm; and his family became anxious about him. The plaster was applied, and gave him immediate relief. A new action was set up; a deep slough, which could not be detached before, was quickly thrown out; he had a daily increase in his comfort; the cavity filled up, and was healed over in a short time. The constitutional condition of this patient was carefully attended to; and, after some weeks, his health was greatly established. He had, however, a succession of boils for months afterwards. There was a large one in each axilla; and, though in a most unfavourable situation for treatment, they were pursued, one after the other, by the same method, with equal success, and with little restraint from business.

I think it right to observe, on this occasion, that it has been long a practice with me to use, with a similar object, and from the same mode of reasoning, a like plan of dressing in various classes of tumours, of a subacute or chronic kind, where there is an evident deficiency in the vital actions of the diseased and contiguous parts: and it has appeared to me more successful in many cases than the ordinary treatment by fomentations, poultices, and embrocations. Where there is an unavoidable suppurative tendency, the plaster will accelerate it better than the cataplasm. When the tumour is disposed to point, the cut edges of the plaster, as in the former case, should be placed directly over where it is desirable for it to open; and I find it well accomplished this object. On this subject, however, I may perhaps enlarge at a future opportunity.

Stockport, July 1st, 1853.

THE TREATMENT OF CERTAIN DISEASES IN REFERENCE TO THEIR PRESENT CHARACTER AND TYPE.

By C. M. DURRANT, M.D., Physician to the East Suffolk Hospital.

(Read before the Suffolk Branch of the Provincial Association, June, 1853.)

"NOTHING, in my opinion, strikes the mind that contemplates the whole and open domain of medicine with greater wonder, than the well known varied and inconsistent character of those diseases which we call epidemic. It is not so much that they reflect and depend upon different condi-

tions of climate in one and the same year, as that they represent different and dissimilar constitutions of different and dissimilar years." These are the remarks of that close observer of nature, Sydenham; and it must, I think, be apparent even to the most superficial inquirer into the varying phenomena of disease, that the symptoms which now present themselves to his notice at the bedside are, in reference to their intensity, their progress, and their termination, of a totally changed and modified character, as compared to the distinct and lucid delineations, to which, as a student, his attention has been more especially directed.

That the type of disease generally has, for some years past, been undergoing important modifications, every practical and observant man must be ready to admit. The routine practice of the books, in the treatment of the pyrexias, for example, all important as it is as a groundwork for the student's guide, and necessary as it was under the influence of an earlier type of disease, must now be adopted with great caution, and only as the result of that discrimination, which close observation at the bedside can alone confer.

The character of disease at the present day is strictly asthenic. In the most acute attacks, the nervous symptoms will be found, very early in the progress of the case, to assume an important feature in its management. The invalid becomes prostrate very rapidly, and if depressing measures be too vigorously prosecuted at the onset of the treatment, increasing exhaustion will obtain, and the patient will sink, despite the most persevering exhibition of stimulants and tonics.

In the following observations, it is not my intention to enter upon the history of the changes which have taken place in the phenomena of disease during the past twenty or thirty years. An able paper upon this subject, by a member of our Association, Mr. Caleb Williams, printed in the last volume of the *Transactions*, renders it unnecessary. To this instructive essay I would therefore beg to refer, while I confine myself to the consideration of the character of some of the diseases peculiar to the three great cavities, with such general observations upon their treatment as reference to the prevailing type appears to demand.

Commencing with affections of the nervous system, we shall find that the severe and acute symptoms, with which we have been familiarised by books and lectures, now obtain less frequently, and in a modified form.

Thus the apoplexia gravior of older authors, requiring for its successful treatment large bleedings, repeated again and again, will now no longer, in the majority of cases, demand this heroic and formerly necessary practice. The type of the disease is changed. The greatest discrimination will be required. The lancet must be used with caution; or we shall surely find that the vital energy will be irrecoverably depressed, and death, preceded by cold clammy sweats, will too speedily close the scene.

In making these observations, I am far from wishing to deprecate the judicious use of the lancet in the treatment of these affections.

I am only anxious to instil caution:—

1. By bleeding only when absolutely necessary.
2. By abstracting the smallest quantity of blood commensurate with the severity of the symptoms.
3. I would caution the young practitioner against too hastily adopting the heroic practice of the books, without well weighing every feature of the case, and at the same time bearing prominently in mind, that the present type of disease generally is of an eminently asthenic character.

Again, in reference to paralysis, so far as my own observations tend to show, we are more familiar now than formerly with this symptom (for it is only a symptom), as a result of cerebral disorganisation—softening. It may be inflammatory, or the contrary; but surely the routine practice of withdrawing a large quantity of blood from the system simply because paralysis obtains, is neither philosophical, nor practically, so far as reported cases in-

dicates, is it attended with success. It is in these cases that local depletion to relieve the capillaries, counterirritation, the prolonged exhibition of the bichloride of mercury in small doses, and stimulating diuretics, including the tincture of cantharides, often prove of signal service.

Epilepsy, again, in the present day, will neither bear, nor does it require, general blood-letting; and if the theory of Dr. Marshall Hall be correct, the laryngismus will not be removed by large depletions.

Not less apparent is the altered type of disease, as evidenced in the cerebral affections of infancy.

Notwithstanding the injunctions laid down by authors, in reference to opening the jugular vein, and the repeated application of leeches, in some of these affections, I must admit that the propriety of doing so is contrary to the experience which my own observation has afforded. Indeed, cases have occurred, in which the abstraction of blood, even by a single leech, has, by further prostrating the already depressed vital power, induced death from irremediable exhaustion.

It will be unnecessary for me farther to advert to the great similarity which obtains, in many cases, between the symptoms arising from the two extremes of cerebral disturbance, as seen in children, viz., the hyperæmic and anæmic conditions of the brain. That the latter exists in the present day more frequently than is imagined cannot, I think, be denied; and if, under these circumstances, even a small quantity of blood be withdrawn from the system, a fatal termination of an hydropcephaloid character may very probably result.

It is in these cases that a well regulated diet, with strict and daily personal inspection of the alvine evacuations, coupled with the exhibition of the salts of iron, and above all, cod-liver oil, will often, even under apparently hopeless circumstances, be attended by the happiest results.

It is not, however, only in the anæmic condition of the brain above referred to, that we are to exercise such caution in the use of depletory measures, but also in those cases of a more acute character, which formerly required and were benefited by a correspondingly active treatment.

Passing from the head to the chest, we cannot fail to notice the result of the asthenic constitution, as evidenced more particularly by pleurisy and pneumonia. I need only appeal to the experience of those who have been in practice some years, to be assured that they are now called upon to use the lancet much less frequently than formerly.

The observations of all, if carefully made, will equally prove that the symptoms of these very acute diseases, are now frequently far from being of that sthenic decided character, which formerly required such vigorous and active depletory treatment.

Again and again, have I witnessed the difficulty which has been experienced in restoring the powers of the system during the convalescence from pneumonia, previously reduced by only a single bleeding.

The character of the symptoms is changed, and the tendency of pneumonia now is, unless the vital tone be sufficiently maintained, to assume a chronic form; the lung becoming more or less condensed by conversion into a dirty greyish mass of cacoplastic deposit.

Another termination of the low form of pneumonic inflammation, by no means unfrequent under the influence of the present type of disease, is gangrenous abscess; and although the prognosis in reference to recovery under these circumstances is, on the whole, favourable, still the necessity of refraining from the indiscriminate use of the lancet cannot be too strongly urged, in order to avoid the inducement, by lowering measures, of this formidable complication. Inflammation of the serous membrane, whether of the chest or abdomen, is equally prone to the depressing influence of the prevailing type. Acute pleurisy and peritonitis are now, numerically speaking, of rare occurrence when compared to the great frequency of these affections under a more asthenic form.

Instead of the severe stabbing pain, and intense fever, with the progressive well known symptoms, formerly so

constant accompaniment, we are now frequently called upon to combat an amount of disease, the existence of which, from the negative character of the direct symptoms, has been almost unsuspected by the patient himself. It must have occurred to all to be surprised at the amount of thoracic, as well as abdominal disease, in connexion with inflammation of the serous membranes, which has been found to obtain, while the patient, farther than feeling weak and somewhat out of health, has scarcely been compelled to forego his usual occupation.

In these cases, if a too lowering treatment be adopted, the necessary reparative powers will inevitably be interfered with; and a cacoplastic, or even tuberculous deposit upon the membrane, with a dirty, shreddy collection of sero-purulent fluids within its cavity, will be the result of the too active remedial interference.

Not only to the diseases to which I have thus in the foregoing observations very cursorily alluded, but also to fevers, puerperal affections, and the whole extensive range included within the limits of toxæmic influence, will similar remarks apply.

In conclusion, I may state, that in troubling you with these observations, it has not been under the impression that I could advance anything novel, but because I have felt, and daily experience convinces me of the fact, that the amount of influence which is exerted upon disease by its prevailing type is not sufficiently regarded. I have been anxious only to instil caution, and to insure reflection, prior to using as a routine necessity the powerfully depressing measures which we possess, and by the indiscriminate adoption of which we expose ourselves to the impertinent inuendos and insinuations of the followers of the leading quackery of the day.

The judicious abstraction of blood by the lancet will unquestionably every now and then be necessary; but he who will allow himself to regard its use as an exceptional, rather than as a necessary part of the treatment of the majority of diseases as they at present obtain, will prove, I can but think, the most successful practitioner. The tendency of inflammatory affections, particularly of the lung, while it exalts the sensibility of the diseased portion, undoubtedly depresses the system generally. An active eliminative treatment, powerfully operating through the three great channels of the skin, the bowels, and the kidneys, may, in the majority of cases, be beneficially substituted for general bloodletting.

These measures, by avoiding the unduly lowering the powers of life, and by not interfering with the process of repair, so necessary to the cure, will tend to insure a safe and comparatively short convalescence, free from that depressing debility to which, in the strumous subject, is so frequently to be traced the first commencement of tuberculous cachexia.

Ipswich, July 1853.

CASE OF RECOVERY AFTER COMPOUND FRACTURE OF THE FRONTAL BONE, AND LOSS OF CEREBRAL SUBSTANCE.

By GEORGE MALLETT, Esq.

THE following case of severe cerebral injury is, I think, important and interesting. It proves very decidedly that *Nil desperandum* ought to be the motto of a surgeon; and it also exhibits in a remarkable manner the wonderful power of nature in repairing injuries that are apparently mortal.

CASE. R. Booth, aged 60, a stonemason, was struck on the forehead by the handle of a windlass in rapid motion. He was taken up by his fellow labourers quite insensible, and conveyed to his house, about a quarter of a mile from the spot.

The medical gentleman residing in the neighbourhood soon saw him; and considering the case to be utterly hope-

less, and that life could not continue many hours, he came to the conclusion that nothing could or ought to be done.

The accident occurred in the afternoon; and on the following morning I was requested to visit the man, as he was still alive.

Upon examination, the frontal bone was found to have received a compound fracture and to be much shattered. The entire breadth of the bone, and from one inch to an inch and a half of its height were driven into the brain. A very considerable quantity of the cerebral matter was adherent to the adjoining parts.*

The man was quite insensible; the breathing was slow and almost stertorous; the pulse slow and full.

I had formerly seen some desperate cases of cerebral injury, which recovered: an account of which was published in the seventh volume of our *Transactions*. I therefore at once resolved to remove the fractured pieces of bone and give him a chance.

Mr. B., the medical man who had seen the case on the preceding evening, was sent for; but he not being at home, I, with the assistance of a medical friend, proceeded to remove the shattered fragments of the frontal bone, some of which were found deeply imbedded in the substance of the brain. Twelve pieces of various sizes were removed, and still the man remained quite insensible to our operations; but on the extraction of the thirteenth, and, as it proved, the last, which was a larger piece and more deeply imbedded than the others, he started up in bed and uttered—no doubt from his accustomed habit, and quite unconscious of what had been going on—an oath. Water dressing was applied, and the head was directed to be kept cold by the constant application of that fluid to the scalp.

I saw him on the following morning, and found him quite sensible, and exhibiting no unfavourable symptoms. I left him in charge of the neighbouring surgeon, requesting that his bowels should, if necessary, be occasionally relieved by a little castor oil; and we agreed that if any unfavourable symptoms should arise, I should be immediately informed. The only intelligence I had was, that he was gradually advancing towards a restoration to health; and after a few weeks I heard no more of the case, and therefore concluded that all was well.

About three months after the accident, I was greatly surprised and pleased to see the man enter my surgery, having walked from his own home, the distance being from three to four miles. The wound was completely healed by granulations, but had left a most frightful deficiency of bone. The pulsations of the brain were seen immediately under the newly formed skin. His intellect, as far as I could judge, was unimpaired; and the muscular power not at all paralysed. In fact, I may say, as he did, that he was quite well. I never saw him afterwards; but I was quite convinced, and endeavoured to convince him, how precarious his existence must be without the greatest care, from the very delicate and insufficient protection which the anterior portion of the brain possessed, being deprived of so large a portion of the frontal bone, no reproduction of which was to be expected.

Bolton, July 2nd, 1853.

[This interesting case is another illustration of the impropriety of forming an absolutely unfavourable prognosis in certain cases of compound fracture of the skull, even when accompanied by considerable loss of cerebral substance. Recoveries are not at all uncommon, when the bone which is broken is the *frontal*, and the portion of brain lost belongs to the same region. Confirmation of this remark will be found at p. 375 of our *Periscope Review* for 29th April.—EDITOR.]

* The quantity of brain lost could not be accurately estimated, but it was not thought to be less than from one to two tablespoonfuls.

ASSOCIATION INTELLIGENCE.

SOUTH WESTERN BRANCH:—NOTICE OF ANNUAL MEETING.

The Annual Meeting will be held by direction of the President-elect, Baruch Toogood, Esq., on Wednesday, July 27th, at Webb's Royal Hotel, Torquay. The Chair will be taken precisely at one o'clock.

The dinner will be at Webb's Hotel, at four o'clock. Dinner and dessert, exclusive of wine, 8s.

Those who propose to dine, are requested to intimate their intention to Mr. Toogood, or to the Secretary, before the 24th instant, that definite arrangements may be made.

W. D. KINGDON, M.D., *Secretary*.

METROPOLITAN COUNTIES BRANCH:—NOTICE OF ANNUAL MEETING.

The Annual Meeting will be held at Mr. Lovegrove's Brunswick Hotel, Blackwall, on Tuesday, July 19th, at 4 P.M., precisely. The Members will dine together at 6 o'clock.

Dinner 10s. 6d. each, including ices and dessert.

JOHN FORBES, M.D., *President*,
T. OGIER WARD, M.D., *Hon. Sec.*

SHROPSHIRE BRANCH:—NOTICE OF ANNUAL MEETING.

The next Annual Meeting will take place at the George Hotel, Shrewsbury, on Tuesday next, the 26th inst. The chair will be taken by Robert Broughton, Esq., of Ruyton, President, at 12 o'clock. The members will afterwards dine together at 4 P.M.

T. J. DRURY, M.D. } *Hon. Secs.*
J. R. HUMPHREYS, }

SUFFOLK BRANCH:—ANNUAL MEETING.

The Anniversary Meeting of this Branch took place in Ipswich, on the 24th of June, under the presidency of ROBERT MARTIN, Esq., of Holbrooke. There were also present—Henry Bartlett, Esq. (Ipswich); John Beales, Esq. (Halesworth); J. Beddingfield, M.D. (Needham Market); B. Chevallier, M.D. (Ipswich); P. M. Duncan, M.D. (Colchester); C. M. Durrant, M.D. (Ipswich); William Ebdon, Esq. (Haughley); Spencer Freeman, Esq. (Stowmarket); Edward Gross, Esq. (Earl Soham); John Growse, Esq. (Hadleigh); C. Hammond, Esq. (Ipswich); Wm. Jeaffreson, Esq. (Framlingham); Robert Jones, Esq. (Melford); J. Kirkman, M.D. (Melton); W. P. Kirkman, Esq. (Melton); George Mingay, Esq. (Wilby); William Muriel, Esq. (Wickham Market); Roger Nunn, Esq. (Colchester); James Pennington, Esq. (Needham Market); Charles Read, Esq. (Stradbroke); George Sampson, Esq. (Ipswich); B. Symmons, Esq. (Bures); — Wake, Esq. (Hadleigh); W. Waylen, Esq. (Colchester). The following visitors were also present: James Francis, Esq. (Ipswich); C. Garneys, Esq. (Bungay); Dr. Junod (Berne, Switzerland); A. Partridge, Esq. (Colchester).

Dr. BEDDINGFIELD, the retiring President, took the chair, and spoke as follows:—

GENTLEMEN,—When I had last the pleasure to address you from this chair, I expressed my regret at the retirement of a gentleman* who had filled it so worthily, so wisely, and so well, in order to make room for one much less competent to the discharge of its duties; but, upon the present occasion, instead of expressing regret, allow me to congratulate you upon your appointment of so highly qualified and so highly gifted a successor. Of this I feel persuaded, that my friend, Mr. Martin, will do honour to your choice.

For the honour you conferred upon me by appointing me your President for the past year, accept my sincere acknowledgments and heartfelt thanks. It now only remains for me to request that Mr. Martin take possession of the chair, which I now vacate with my best wishes for the continuous prosperity of our Association.

ROBERT MARTIN, Esq., having taken the chair, spoke as follows:—

PRESIDENT'S ADDRESS.

GENTLEMEN,—With great pleasure I accept your presidential chair, and thank you much for the honour your election of me has conferred. The duties which the office imposes I will endeavour to discharge with zeal, and with such ability as is

* Mr. Jeaffreson, of Framlingham.

placed at my disposal. It is not my intention to trespass on your valuable time by a lengthy address, as I rejoice to learn that able heads and able pens have been engaged in preparing papers and cases of interest for our instruction. Thus then, briefly but sincerely thanking you, I at once proceed to direct your attention to the important business of the day.

It affords me much satisfaction to inform you that my good friend, Dr. Kirkman, who has so efficiently discharged the duty of honorary secretary for some years past, kindly consents to continue his exertions during the year of my presidency; and that Dr. Durrant has graciously agreed to hold the office of vice-president.

It has been generally admitted that the establishment of our Medical and Surgical Association has been a benefit to us, not merely *en masse*, but individually, by bringing before us the experience and the opinions of the many, and by the effect of social intercourse in polishing off those angularities inevitably resulting from exclusiveness. Yet, valuable as the institution has proved, it is insufficient for the attainment of all those desiderata, which might be effected by the more frequent meetings of the members of its various branches. In the present unsettled state of our profession, many subjects of general interest arise, in which unity of action (most important to our welfare) can alone be attained by consultation and discussion.

Within the past year, subjects of importance have transpired, on which, as a body, the members of the Suffolk Branch have recorded no opinion, and are in fact nonentities with regard to these matters which deeply affect their individual and common interests. These are the Professional Income-Tax, the Vaccination Extension Act, and the Medical Reform Bill; on which latter, petitions and counterpetitions are at this moment so bewildering. Lords Aberdeen and Palmerston, that the latter may well define Medical Reform to be a fearful labyrinth and chaos. I have this morning received from my friend Mr. Kelson (of Seven Oaks), together with his expressions of regret at not being able to be with us this day, a copy of a letter addressed by him to Lords Aberdeen and Palmerston, as well as Lord Aberdeen's reply, both of which, with your permission, I will read. (The President here read the letters, which have been published in the daily papers.) I produce these letters in support of my assertion, that more frequent meetings are required to produce unity of action among us, and to render individual interference unnecessary, if not unseemly. And last, though far from least, of the subjects requiring these more frequent meetings, is the homœopathic question; a system fraught with danger to the public, and, for a season, with serious consequences to the regular practitioner, who, after devoting his patrimony and his life to the study of his profession, is treated with distrust, contempt, and even the hatred of partizanship, by the dupes of the reigning fallacy. If its dogmas be true, let them be adopted; but if they be based on error, and supported by falsehoods, those errors and falsehoods should be publicly exposed, not merely in medical, but in general periodicals; that the antidote may be administered where the poison has been imbibed. The main support of the homœopath, the system of expectancy, or the trusting the cure of disease to dietetics and the *vis medicatrix nature*, is of very ancient date. Asclepiades, the cotemporary and friend of Cicero, who was born 106 years before the Christian æra, denounced the indiscriminate use of medicines by the practitioners of his day; and trusted almost exclusively to mental excitement and dietetic means for the removal of chronic disease. Pliny the elder, about one hundred and fifty years afterwards, denounced him as an impudent quack, who gained practice by humouring the whims of his patients, and ministering to their imaginations, and not to their diseases. Asclepiades, however, the first practitioner to draw a line of distinction between acute and chronic diseases, and an upholder of the corpuscular theory, whose keen observation could discriminate those cases which with safety could be entrusted to the influence of dietetics and excited imagination, would have scorned the globulistic humbug of the present day.

The ascendancy which this absurdity has obtained over the minds of some, in other respects able and intelligent individuals, may be exemplified by the following authentic anecdote. A gentleman in this town, of the highest respectability, insisting on the marvellous effects of infinitesimal doses, assured me that, as the result of taking a single globule containing only the billionth part of a grain of sulphur, a silver pencil-case, worn in his waistcoat pocket, was blackened by its influence! He was ignorant of the fact, that a far larger portion of sulphur formed a component of his own body; and unmindful of the circumstance that, while using his pencil-case, his fingers were in frequent contact with vulcanised India-rubber bands, used for hold-

ing papers, which afforded a more probable solution of his problem, than the billionth globule of a grain of sulphur. Argument, however, prevailed nothing.

"The man convinced against his will,
Is of the same opinion still."

He lived and died a homœopath.

Opportunities for discussing subjects of professional interest appear to me a great desideratum; one, however, I think, might be readily supplied in this locality, by grafting, on this our Annual Meeting, a Quarterly *Soirée Médicale*, to be held in Ipswich, and presided over by the President for the year, after the manner of the London Medical Societies. At such meetings, subjects of medico political interest, of irregular practice, and of medical ethics, might be discussed; papers likewise might be read, and cases reported. This would afford a supply of intelligence for our Journal, make known our sentiments throughout the whole Association, and constitute a legitimate field for honourable emulation. Should this idea meet more than one concurrent mind, it may probably appear before you in the form of a proposition, to be dealt with according to your estimate of its merits.

LETTERS FROM ABSENT MEMBERS.

The Secretary (Dr. Kirkman) read letters expressive of regret for non-attendance, from Dr. Hake (Bury); Dr. Ranking (Norwich); Edward Lock, Esq. (Debenham); R. V. Gorham, Esq. (Aldburgh); George King, Esq. (Hartest); William Worthington, Esq. (Lowestoft); William Mudd, Esq. (Hadleigh); Geo. Mayhew, Esq. (Stradbroke); Dr. Lanchester (Yoxford); R. R. Carley, Esq. (Laxfield); C. R. Bree, Esq. (Stowmarket); Geo. Humphrey, Esq. (Cambridge); Dr. Wake, and James Williams, Esq. (Southwold).

Letters were also read from several distant members of the Association, who, though not connected with this Branch, would have been present if practicable.

NEW MEMBERS.

The following new members were proposed and admitted:—George Mingay, Esq., of Wilby, by Dr. Durrant; George Bullen, jun., Esq., of Ipswich, by Henry Bartlett, Esq.; B. Harling, Esq., of Stowmarket, by Dr. Kirkman; and Dr. Gillam, of Aspell, by Edward Gross, Esq.

CASES AND COMMUNICATIONS.

1. H. BARTLETT, Esq., introduced two patients to the notice of the meeting. One was a case of excision of the elbow-joint in a female, after disease of eight years standing. The other was a successful case of Syme's operation, which excited great interest among the members generally.

2. Dr. DURRANT read a paper on the prevailing type of diseases of this period, which led to a good deal of discussion between the President, Dr. Duncan, Dr. Durrant, and Mr. Read. [This paper appears as an Original Communication, at p. 608.]

3. Mr. GROSS introduced Dr. Junod, of Berne, to the meeting, and made the following remarks on the instrument which he brought before them.

In drawing attention for a few moments to this valuable invention by Dr. Junod, called *Méthode Hémospasique*, I much regret that it has not found a more efficient exponent than myself; but, while I beg your indulgence, I must request your attention to a very useful therapeutic agent in most cases where blood-letting would be beneficial; and this too without any of the ill consequences too frequently attending upon it. It is now twelve months since it was first introduced to my notice by Dr. Junod. Since then, I have frequently used it; and by way of illustration, I will briefly mention a few instances in which I found it particularly serviceable.

The most important case in which I proved its efficacy, was one of strangulated hernia in a man 72 years of age, who refused to submit to an operation. For eight days it resisted every means that my experience could suggest to reduce it (except bleeding, and this I dared not hazard in his exhausted state). As a last chance, I resolved to test the efficacy of Dr. Junod's *appareil*. At this time, the patient was suffering acute pain in the abdomen, with hiccup and stercoraceous vomiting, and a sinking pulse. In half an hour, the more urgent symptoms gradually subsided, the pulse became firmer, and he sank into a quiet sleep, suffering but little pain during the night. Early the next morning, I was able to return the formidable mass without difficulty; and, after a few weeks, during which he suffered from extreme debility, the patient was restored to his usual health.

The next case worthy of note, was a child, aged four years, who inhaled the steam from a kettle of boiling-water, producing acute laryngitis. When brought to my surgery at seven o'clock

in the evening, the child appeared almost in a dying state. Its pulse was frequent, feeble, and irregular; its face livid; breathing difficult; the brain oppressed; and the extremities cold. I immediately applied the *appareil*, continuing its use occasionally, as I found from the state of pulse the little sufferer could bear it. During this time, I also applied mustard plasters to the throat and chest, giving small doses of calomel, and moistening its mouth with a little warm arrow-root. In four hours, the child was sufficiently relieved to be taken home; and, after a few days, during which I gave a little calomel and antimonial-powder, it was restored to perfect health.

Again, in the inflammatory stages of whooping cough, I have used it with marked success, applying it every third or fourth day, as the urgency of the case required, and never failing to relieve the violence of the cough and febrile symptoms. In fact, in almost all the diseases of children, where local or general bleeding appears necessary, this derivative is in my opinion far preferable to depletion.

In cases of paralysis, congestion, aggravated hysteria, and suppression of the catamenia, I have found it eminently serviceable, sometimes as a valuable auxiliary to medicine, occasionally even superseding the necessity of it.

But not to occupy your time with any further details of my own limited experience, I would at once refer you for a fuller exposition to my friend Dr. Junod, its inventor, whom I now have great pleasure in introducing to this meeting.

Mr. JEAFFRESON supported the opinion of Mr. Gross, and referred to cases where he had successfully used the instrument.

Dr. JUNOD detailed the minutiae of its application.

4. Dr. DUNCAN read a case of great interest, of extensive disease of the chest, with unusual symptoms; and another of disease of the knee-joint.

5. Dr. CHEVALLIER read a case of endocarditis.

A delicate looking but generally healthy girl, aged 12, who had been ailing for some days, was attacked on the 14th March with deep seated pain in the right hypochondrium, extending to the loin, and occasionally shifting its position. She was found to be labouring under symptoms of rheumatic fever; the joints of the lower extremity became successively affected. The treatment up to the 18th had consisted of salines and diaphoretics; but on this day, calomel and opium were given. On March 20th, she complained of pain in the region of the heart; a slight blowing murmur was heard to accompany the first sound; it was most distinct at the apex. A blister was at once applied. Subsequently the joints of the upper extremities became affected. She recovered: and on June 14th, was considered by her friends as perfectly well. There still remained a loud bruit, and a slight increase in the heart's impulse, but without palpitation or pain of any extent. Dr. Chevallier had hoped at first that this was one of the rare instances of acute rheumatism alluded to by Dr. Walshe, where the systolic sound at the left apex is roughened and murmurish for a few days, but then loses this quality entirely. He now, however, feared that there was lasting injury to the mitral valves.

6. Mr. WILLIAM P. KIRKMAN related a case of suicidal melancholia, in the Suffolk County Asylum, in which, after repeated attempts at self-destruction, the patient swallowed seventy-two stones ineffectually.

PLACE OF MEETING FOR 1854.

The following resolution was proposed by Dr. BEDINGFIELD, and seconded by JOHN GROWSE, Esq., and unanimously carried: "That the place of meeting for 1854 be Bury St. Edmunds; and that Dr. Probart be requested to take the chair."

VOICES OF THANKS.

It was proposed by HENRY BARTLETT, Esq., and seconded by CHARLES HAMMOND, Esq.:

"That, from the acknowledged omission at the last meeting, to embody in a resolution the thanks due from this Branch of the Association to their late Secretary, C. R. Bree, Esq., for his valuable services since the formation of the Suffolk Branch, till his resignation in 1851, the thanks of this meeting are now most cordially conveyed to him for the same, coupled with expressions of regret at his loss."

It was proposed by SPENCER FREEMAN, Esq., and seconded by JOHN BEALES, Esq.:

"That the best thanks of this meeting be expressed to those gentlemen who have recited cases and read papers."

It was proposed by WILLIAM JEAFFRESON, Esq., and seconded by WILLIAM MURIEL, Esq.:

"That the best thanks of this Association be given to the Directors of the Eastern Union Railway, for the use of their room at Needham Market last year."

It was proposed by HENRY BARTLETT, Esq., and seconded by Dr. KIRKMAN,

"That a cordial vote of thanks be given to Dr. Bedingfield, for his hearty services as President, throughout the past year."

After a vote of thanks unanimously proposed and seconded, to the President, Robert Martin, Esq., the meeting adjourned at 5 o'clock to dinner.

THE DINNER.

About thirty members assembled at the White Horse. The interests of the Association were not lost sight of in the social intercourse of the evening.

Among other topics, the appointment of sub-committees, with occasional meetings for special purposes on the pressing questions of the day, was urged on the attention of the members; and, after affording full evidence of unity of principle and expressions of determined unity of action for the professional and public good, the meeting separated with friendly cordiality.

LANCASHIRE AND CHESHIRE BRANCH: ANNUAL MEETING.

The annual meeting of the Lancashire and Cheshire Branch of the Provincial Medical and Surgical Association was held at the Town Hall, Manchester, on June 29th. The following gentlemen were present:—E. Batty, Esq. (Liverpool); C. W. Bell, M.D. (Manchester); James Black, M.D. (Bolton), President for the year; S. T. Chadwick, Esq. (Bolton); S. Crompton, Esq. (Manchester); G. Daglish, Esq. (Wigan); Oswald Dicken, Esq. (Middleton); J. Dickinson, M.D. (Liverpool); A. W. Dumville, Esq. (Manchester); T. Eden, Esq. (Liverpool); E. L. Falloon, Esq. (Liverpool); J. S. Fletcher, Esq. (Manchester); John Galt, Esq. (Ashton-under-Lyne); Joseph Godden, Esq. (Oxton, Birkenhead); H. Halkyard, Esq. (Oldham); J. Bower Harrison, Esq. (Manchester); John Hatton, Esq. (Manchester), Honorary Secretary; Dr. Heckscher (Manchester); John Howe, Esq. (Marple); Ellis Jones, Esq. (Liverpool); J. M. Kirkman, Esq. (Manchester); A. O. Leete, Esq. (Newton-le-Willows); E. Lund, Esq. (Manchester); R. H. McKeand, Esq. (Manchester); T. Mather, Esq. (Ashton-in-Mackerfield); J. Medd, Esq. (Stockport); G. Mallett, Esq. (Bolton); T. Mellor, Esq. (Manchester); D. Noble, Esq. (Manchester); J. Nottingham, M.D. (Liverpool); J. Pendlebury, Esq. (Bolton); J. F. Pennington, Esq. (Ashton-in-Mackerfield); W. B. Pickering, Esq. (Denton); T. G. Richmond, Esq. (Manchester); John Robertson, Esq. (Manchester); J. M. Robinson, Esq. (Bolton); G. Southam, Esq. (Manchester); H. Swift, Esq. (Liverpool); Alexander Thom, Esq. (Dobcross); F. Tinker, Esq. (Hyde); Thomas Turner, Esq. (Manchester); A. T. H. Waters, Esq. (Manchester); E. Waters, M.D. (Chester); W. J. Wilson, Esq. (Manchester); M. A. Eason Wilkinson, M.D. (Manchester); J. Woollam, M.D. (Ashton-under-Lyne); G. Woolstenholme, Esq. (Bolton); etc.

In the absence of Mr. BICKERSTETH, President for the past year, Mr. ELLIS JONES, of Liverpool, was called to the chair, and, after a few remarks he resigned his position to Dr. BLACK, president for the year.

PRESIDENT'S ADDRESS.

GENTLEMEN,—I return you my best thanks for the distinguished honour you have, on this occasion, conferred upon me. Instructed and encouraged by the example of my worthy predecessors, I shall endeavour so to fulfil my duties, that however short they may come of your requirements, they may, at least, avoid occasion of injury.

Allow me to congratulate my fellow associates on the continued prosperity of this elder Branch of the Association. With our Parent, we have always lived on terms of goodwill and useful cooperation for the progress and honour of our common profession; and, though equal to any of our sister branches in respect and allegiance to our Parent, we have never been, for these seventeen years, indebted to her for the least part of our maintenance. We have, on the contrary, contributed to the Benevolent Fund of the Association from our savings.

Though we have of late years celebrated our anniversaries at the great *termini* of trade, manufacture, and science in the county Palatine, under the ægis and shade of the first men and names of our profession; yet, humbly speaking for myself, my more numerous associations with this branch are in my memory connected with our former resort in *medias vias*, espe-

cially when I remember that a Holme, a Jeffery, and a Kendrick there regularly shed a venerable grace and honour on our discussions and entertainments.

Since we last year met under the respected and urbane presidency of Mr. Bickersteth, at Liverpool, important subjects have been agitated—subjects which have not only affected the economy of the PROVINCIAL ASSOCIATION, but which have also excited a deep interest throughout the profession. Though this branch last year was, in a manner, called upon to declare its opinion regarding the measure then proposed for the change of the place of publication of the JOURNAL, previous to the decision of the question at Oxford, it was thought expedient, after a good deal of consideration, to pronounce no decided opinion—unprovided as many of us were with data as to the means and talents which the proposer of the change had in view for the benefit of the ASSOCIATION. The change was, after a good deal of opposition and some little discussion and chagrin, decided upon at Oxford: and we have now had about six months observation and experience to enable us to judge, how and how far the publication has fulfilled the promises and hopes of those favourable to the removal to London: and in what degree have been satisfied the wants and desires of the members at large. It would be irrelevant to my present office to criticise the new series of the JOURNAL. I may, however, be permitted to say that I think we have gained in a literary, medical, and scientific point of view; though I could have rather wished to have seen such valuable returns issuing from the provinces, and the prefix of "PROVINCIAL" still attached to the title of our periodical. As it is likely that the expenses of a weekly Journal will be a heavy charge upon our general finances, members must probably make up their minds to be deprived of the Annual volume of Transactions. This, to some, may be a subject of regret; while others may conceive that they are compensated by the more copious information afforded by a weekly JOURNAL.

Owing to the pressure of business in the hands of Her Majesty's Ministers, the struggling patient, Medical Reform, seems to be left to the *placebos* of the day, or till the aggravation of symptoms requires immediate remedies to avert convulsion, or the coma of professional apathy. In any bill for Medical Reform that may be submitted to the legislature, it is desirable that the legal titles to practise be not increased in number, but rather, if possible, be reduced, if we cannot attain to the simple division, in the working part of the profession, into the two classes of the ordinary and consulting practitioners. At any rate, I think there is no need to increase the number by creating, as is proposed by the bill of the Association, a new licentiatehip, which alone would satisfy many entering the profession, without being compelled to proceed to further honours in medicine and surgery. Instead of this, all the members and licentiates of the nineteen universities, colleges, and schools, might, after registration, be legally authorised to practise in all parts of the three kingdoms and colonies, by a simple Act of Parliament made for that purpose. And to render the qualification equal throughout to all noviciates, a *minimum curriculum* of education might be laid down by the Act, for all colleges and other bodies to observe before diplomas or licenses be granted. This would be introducing no new machinery, nor entailing expenses, but only enforcing uniformity, so that equal and universal privilege may be enjoyed. As to registration, there seems no necessity for the erection of a separate Council or Board, with an exclusive staff throughout the country; this very requisite business might easily be effected, for small fees, by the official clerks of cities, boroughs, and counties.

In the public relation of the profession to the State and to those entrusted with the official administration of its subordinate affairs, medical practitioners have still much to complain of, as well in the scanty remuneration for their services, as in the little respect and deference observed to them as members of an educated profession. We have only to instance the internecine struggle still going on between our brethren in practice, throughout many parts of England and Ireland, and the Poor law Guardians. To this deprecatory treatment of medical services and character now in existence since the enactment of the Poor-law, there has, this session, been all but finally passed another onerous call on medical men for their ill-considered and ill-requited labour, in the Vaccination Bill—a measure seemingly brought forth and conducted in Parliament, without the least reference to either the public opinion of medical men, or to the manner in which it could be practically worked out for the benefit of the public and individuals immediately concerned.

However much we have, from these and other unfavourable

causes, to lament the present dissociated condition of the profession, and to remonstrate against each fresh inroad upon our legitimate dignity and privileges, we have every reason, as a profession, to claim no small merit for our endeavours and success in promoting medical science and surgery, by which the ills of mankind are diminished, and the aims of our godlike calling vindicated before the public.

I need not before this meeting specially advert to the great progress that is yearly making in histological anatomy, and in the composition and chemical reactions of all the fluids in the body, aided by the revealing powers of the microscope, and by a more refined process of analysis. We have only to look at the labours of Kiernan, Bowman, Paget, and Johnson, to see how the intricate structure of the liver, the kidneys, and the muscular fibre, have been revealed to us, and how the nature of fatty degeneration and other diseases of these organs and structures have been eliminated by these gentlemen, and successfully treated by a Budd and a Bright. The cell-structure of the glands, and of the nerve fibres, with all the special distribution of motion, sensation, and of organic life throughout them, have had such light thrown upon them, that there seems now only wanting the discovery of the principle of life itself, to make our knowledge of the animal body complete in all its parts. Such knowledge is for us, however, too wonderful to attain to; and notwithstanding all the insight we have acquired into the arcana of structure and function, we are still compelled, in the treatment of diseases to which these are liable, to bring in, for a successful and beneficial solution of the problem in which we may be engaged, the important element of experience: for, as Sydenham says, "*Experientia, optima duce et magistra, ad cujus leges et normam nisi exerceatur medicina, eam prorsus exulare satius esset*". In taking experience for our leader and mistress, we must at the same time be prepared to give a scientific reason for the faith that is in us, and not act like those who appeal to alleged facts of successful treatment, without knowing, or pretending to know anything of the nature and functions of the organs upon which they empirically or superstitiously operate. For, though we have not been able to detect the initial germs of many diseases in the blood and fluids of the body, yet we know how they are affected when once developed, how the vessels and secretions are modified or altered; and from a knowledge of their physical and chemical metamorphosis, we can so far apply therapeutics derived from our experience in similar or analogous instances, with such curative result, as to stamp the exercise of our profession with the appellation of one of philosophy and science.

The progress and advancement of rational and bold surgery have also increased their claims upon the estimation and gratitude of the public, as may be witnessed in the improved and expectant treatment of fractured and contused limbs, which were formerly consigned to primary amputation, but are now, in many cases, saved, and made more or less useful to the sufferer. The excision also of diseased joints has been successfully adopted in cases where once no measure was ever thought of but amputation of the limb; and in these, the later days of surgery, the removal of the largest tumours from the pelvis and abdomen has been performed, and with a success equal to the average recoveries from our capital operations on other parts of the body.

The science and practice of therapeutics are also daily becoming more simplified and improved, to the benefit of the patients' health, the mitigation and abolition of pain in severe operations and in childbirth, and to the diminishing of the apothecaries' bill; though there are yet some grounds for thinking that the latter part of the benefit, owing to the want of intellectual progress in the vulgar mind, is not so justly appreciated as it should be, for a *big bottle of stuff* is yet too commonly associated with the alleged amount of talent and attention in the prescriber or dispenser.

The great and important question of sanitary measures is also highly indebted to the medical profession, for the philosophical and practical views that are and may be brought into operation for the preservation of the public health and the promotion of longevity; though medical men have never countenanced the enthusiastic views of lay staticians and official empirics, that the average mortality in such places as Manchester may be brought down to that of the valleys and plains of Westmoreland and Cumberland.

Gentlemen, in venturing to bring before you, in a very textuary manner, some of the principal points in the polity of our profession, as well as setting forth some of the claims we have to the respect and estimation of the public, I would further presume to invoke your continued energy and persever-

ance in the noble pursuit in which we are engaged—irrespective of official prescriptions and interpolations, on the one hand, and of the hosts of dishonest pretenders and quacks, on the other. Narrowed though the sphere of legitimate practice may become, from the bold inroads and illicit attacks of these various invaders of the rights, privileges, and emoluments of our profession, still, with truth, science, and experience on our side, we shall ultimately prevail, and vindicate our calling as one worthy of all acception.

[We have been obliged to omit very many paragraphs, and condense others, doing thereby a great but an unavoidable injury to this address.—EDITOR.]

Mr. HATTON, Honorary Secretary, read the

REPORT OF COUNCIL.

The Council, in presenting their Annual Report, congratulate the members upon having arrived at their seventeenth anniversary celebration.

To prove that the profession do not consider this Branch to have retrograded in its energy and usefulness, they have the satisfaction to state that, during the past year, fifty-five new members have been enrolled. This fact is highly gratifying at a time when the united strength of the profession is required to accomplish that desirable realisation of medical reform, for which the entire Association has so long been exerting its most strenuous efforts, viz.

1. Uniformity of qualification.
2. Equal right to practise throughout the United Kingdom; and
3. Representative councils for the governance of the profession.

The Council had hoped to be able to report to the Anniversary Meeting a satisfactory termination to the question; but from what has recently transpired in the House of Commons, and more especially from the observations of the Home Secretary, they are apprehensive that there is little likelihood of the matter being finally settled during the present session of Parliament.

They recommend, however, that the following Petition shall be signed by the President and Honorary Secretary, on behalf of this meeting, and be forwarded for presentation to the two Houses of Parliament.*

The Council have to explain to the members assembled, that the discretionary power given to them at the last anniversary, to alter the place of meeting from Chester to Manchester "if necessary", has been exercised by them for the welfare of the branch, as they found but few members of the profession in the former locality likely to co-operate very actively in procuring a numerous and influential meeting. The experiment has been made on two separate occasions; and the Council are unanimously of opinion that, *for the present*, it is for the well-being of the Branch to alternate the anniversary meetings between Liverpool and Manchester. Nevertheless, if the profession in any of the larger towns in this increasing and improving district willingly come forward, and give the Council such reasonable assurance of support as to render probable a numerous and successful meeting, they would gladly recommend the anniversary celebrations to be held in various places, being convinced that the Association has only to go into new and untried ground to provoke union of all legally qualified and respectable practitioners.

The Council have to announce the gratifying result, that from the limited subscription of 2s. 6d. per member annually, the Branch has not only been able to clear itself of a debt which was yearly increasing when the subscription was but optional, but has been enabled through the liberality of the last annual meeting, to hand over a donation of five pounds to the Treasurer of the Benevolent Fund. As this is the only instance of the kind in the experience of Branches, they trust that others will follow the example of the Lancashire and Cheshire Branch, and henceforth pay their own expenses, in order that the Association at large may be as little stinted as possible in the finances.

Another subject to which the Council would allude, is the Vaccination Bill recently introduced by Lord Lyttelton. There are some clauses in the Bill to which they would give their support; but there are others so decidedly objectionable to the profession, that they request the members here assembled to sign the Petition in the hands of the Honorary Secretary, praying that the Bill may not become a law until the profession

* The petition is the same as that published at p. 280 of the *Association Journal* for May 6th.

have had ample time and opportunity for considering its provisions and expressing their feelings and opinions thereupon.

OBITUARY. During the past year, the Council have to lament the loss by death of four active and valuable associates, viz.—Dr. Thomas Jeffreys, late of Liverpool; Mr. Thomas Fawsitt, of Oldham; Mr. Sumner, of Lynn; and Mr. Mather, of Ashton-le-Willows.

FINANCES. After paying a donation of five pounds to the Benevolent Fund, there remained last year a balance of £2:1:7 in favour of the Branch. Since the last anniversary, the receipts have amounted to £14:2:6, and the expenses to £18:3:2, which leaves a balance of £3:0:11 in favour of the Association.

The expenses during the past year have been rather heavier than usual, in consequence of having a *verbatim* report of the proceedings at the last anniversary, and of the Secretary having issued five hundred circulars to all legally qualified and respectable practitioners within the limits of the Branch to induce them to join the ranks of the Association.

Although the responses have not been as numerous as the Council would desire, yet they hope the way has been paved for the individual members of the Branch to induce their fellow-practitioners to join their ranks, and by becoming united, to further the objects they have in view, viz.—

“Maintenance of the honour and respectability of the profession, in the provinces, by promoting friendly intercourse and free communication of its members, and by establishing among them the harmony and good feeling which ought ever to characterise a liberal profession.”

Mr. F. TINKER, of Hyde, said: I have very great pleasure in moving—

“That the Report of the Council now read be adopted, and transmitted by the Secretary to the Editor of the JOURNAL for publication, together with the proceedings of this meeting.”

I must, Sir, express my satisfaction at the manner in which you have, in your address, alluded to the measures that have been taken with a view of improving the position of those members of our profession who are connected with poor-law unions, as regards the meagre salaries meted out to them for services which are of a more than ordinarily arduous character. With regard to the Vaccination Bill, my experience has led me to the conviction that something like an imperative law should be passed on the subject; for, at present, religious prejudices, as I know, do to a great extent interfere with the operation, which we know is so extensively sanitary in preventing a disease not only most malignant in its character, but most dangerous to the community at large. I do not speak without some experience as to the objections raised upon that score. Much good might be effected, and much assistance given in carrying out the intentions of the legislature, if clergymen, and ministers of various persuasions, would lend their kind and influential aid in disabusing the minds of those with whom they may come in contact, of any prejudice which can at all interfere with the due effect of this wise and truly sanitary measure.

Mr. GEORGE MALLETT, of Bolton, said: The report meets with my entire approbation. With regard to the Vaccination Bill, I have great objections to it in its present form, as I believe we all have; and I think that at present our efforts should be devoted merely to stay its progress. By turning the whole subject over in our minds previous to the next meeting of Parliament, I hope and think that we should be able to come to some unanimous decision as to what is best to be done. As the feeling throughout the profession is so strong and general against it, I do not think that Parliament will press it upon us in its present shape. I have very great pleasure in seconding the motion.

The motion was agreed to unanimously.

ELECTION OF OFFICERS.

Mr. EDMUND LUND, of Manchester, said: The resolution which has been placed in my hands is to the following effect:—

“That the thanks of this meeting be given to the past officers and Council; that the next anniversary be held in Liverpool; and that the following gentlemen constitute the officers and Council for the ensuing year:—PRESIDENT: James Black, M.D., of Bolton. VICE-PRESIDENT: R. Dundas, M.D., of Liverpool. HONORARY SECRETARY: John Hatton, Esq., of Manchester. MEMBERS OF COUNCIL: Samuel Crompton, Esq.; Daniel Noble, Esq.; Thomas Radford, M.D.; George Southam, Esq.; Thomas Turner, Esq.; W. J. Wilson, Esq.;—of Manchester: Edward Batty, Esq.; R. Bickersteth, Esq.; P. Macintyre, M.D.; Joseph Dickinson, M.D.; Thomas Inman, M.D.; Ellis Jones, Esq.;—of Liverpool: George Daglish, Esq., of Wigan; John Halliday,

Esq., of Seacombe; William Lax, Esq., of Ormskirk; John Medd, Esq., of Stockport; J. A. Pearson, Esq., of Woolton; J. M. Robinson, Esq., of Bolton; John Sharp, Esq., of Warrington; and E. Waters, M.D., of Chester. PRESIDENT-ELECT: Joseph Dickinson, M.D., of Liverpool. VICE-PRESIDENTS-ELECT: D. Noble, Esq., of Manchester; G. Mallett, Esq., of Bolton.”

I am sure that, in bringing forward this proposition, it is unnecessary for me to make any observations in commendation of the manner in which the officers and Council have discharged their very responsible duties during the past year. We have all one common interest in associations of this character; but I fear that we all feel, also, somewhat lethargic on the point of taking an active part in conducting them. We all like to participate in the benefits which so necessarily ensue from their existence; but we hardly like to undertake the responsible and increasing duties attendant upon an official connexion with them. For this reason—and quite independent of their deserts for the very efficient manner in which their duties have been performed—I am sure you will agree with me that the officers and Council for the past year are in every sense most deserving of our warmest thanks.

Dr. NOTTINGHAM, of Liverpool, seconded the motion, which was unanimously agreed to.

NEW MEMBERS.

The following gentlemen were proposed, as members of the Parent and Branch Associations:—S. T. Chadwick, M.D., of Bolton; James Pendlebury, Esq., of Bolton; T. Mather, Esq., of Ashton-in-Mackerfield; and John Galt, Esq., of Ashton-under-Lyne.

PRESIDENTS OF THE PARENT ASSOCIATION.

The CHAIRMAN having asked if any gentleman had business to bring before the meeting previous to the reading of papers,

Mr. GEORGE SOUTHAM, of Manchester, said: I have a resolution, which I should wish to propose, with reference to the mode of appointing the Presidents of the Anniversary Meetings of the Parent Society. Reverting to the names of those gentlemen who have held the office of President, you will find that there have been seventeen physicians appointed, and only four surgeons. I know that occasionally it has been a source of difficulty to the parties to whom it has been left to suggest the President, as to whether they should select a physician or a surgeon; as the Association is one consisting of both physicians and surgeons, and as we recognise no other class in the profession. All will admit that surgeons are now quite as well educated as physicians—that there is a difference in name only, not in education. I will therefore propose,—

“That this Branch meeting is of opinion, that the Presidents of the Parent Association are selected too frequently from the class of physicians; and that it is due to the body of surgeons that the President shall be chosen from their order, if not alternately with the physicians, at least much more frequently than is the case at present.”

This suggestion has been sent from this Branch once or twice, but it has not been much acted upon: and I think that it would promote harmony between the two classes of the profession, if some regular plan were followed in the appointment of Presidents.

Mr. SAMUEL CROMPTON, of Manchester, seconded the motion; and it was unanimously agreed to.

THE JOURNAL.

Mr. CROMPTON said: I think that an expression of opinion ought to go forth from this meeting, to the effect that the members of this Branch are satisfied with the great improvement that has taken place in the Journal under the present editorship. My motion would be,—

“That this meeting do hereby express its great satisfaction at the improvement which has taken place in the Journal since Christmas.”

The motion having been seconded;

Mr. DANIEL NOBLE, of Manchester, said: I would submit to this meeting, whether there be any necessity for passing that resolution. I do not at all object to the opinion expressed in it; but I rather doubt whether we ought virtually to pass a reproach upon the Worcester management up to the period of the change. I confess that I do not see the necessity for it, however I may concur in the sentiments which the resolution expresses. It appears to me that it is ungracious to Sir Charles Hastings, and to those other gentlemen, to whom the Association not only owes much for the management, but for the sustenance of the Journal. It is quite gratuitous, to say the least of it, to pass a resolution which virtu-

ally conveys a slight upon them. I shall vote against it, and I hope the meeting will not pass it; for it does convey a slight to those to whom the Association owes much.

The PRESIDENT: Do you move an amendment?

Mr. NOBLE: No; I shall simply vote against it.

The PRESIDENT: It is certainly rather an important question, as to a point of courtesy.

Mr. E. L. FALLOON, of Liverpool: I think, sir, that we have reason to be proud of the present editor of the Journal; and I think, also, that we must all feel that the progress of a publication like ours very much depends upon ourselves—an editor must have much and wide spread assistance. I wish therefore to convince members, that much depends upon ourselves and our contributions. Ours is a provincial journal, and its main support ought not to come from the metropolis; although it is quite proper that its head quarters should be in the metropolis. I wish to throw no discredit upon the previous editors; my reason for rising to support the resolution is to urge that we should each resolve to endeavour to make the Journal as valuable as possible. The editor is as able a man as any in England, but it is impossible that he can do all: he must be supported by contributions from the provinces.

Dr. DICKINSON, of Liverpool: I hope, sir, that the resolution will be withdrawn; for I believe that there would be a vast difference of opinion as to the increased efficiency of the management of the Journal. The resolution casts a very uncalled for slur upon the previous conductors of the Journal, to whom the Association owes so much. Like Mr. Noble, I must vote against it if it be pressed.

Mr. CROMPTON: At Oxford there was a very strong feeling against the former management of the Journal; and I think that the feeling was universal among the members. I remember that, on a former occasion at a meeting of this Branch, when the management was alluded to, there was a very strong outcry against it. Certain members were named as a committee at Oxford to undertake the transfer of the Journal to London, and its publication there under the new management. I was nominated a member of that committee, but I retired when I learned that a majority—if not all—of the committee had resolved in the first instance to offer the appointment to Dr. Cormack. I thought that the editorship of the Journal ought to have been thrown open—that an advertisement ought to have been put into the medical publications, calling for the best talent that the whole kingdom could produce. On that ground I withdrew from the committee; and therefore I may be considered to be at variance with them. I utterly disclaim any feeling of hostility, against either Sir C. Hastings, or anyone else, in bringing forward this resolution. If the Journal has done well for the Association—and it has increased the number of members enormously—I say that it is most ungenerous for us, after having on former occasions given our support to the *Worcester Journal* by remarks at these meetings, not to come forward and support Dr. Cormack, the present conductor, and those who incurred the responsibility of giving practical effect to the Oxford resolution. If the Worcester members take offence at it, I say that is not intended to give them offence; it is, as it purports to be, simply intended to express the satisfaction which this meeting feels at the manifest improvement in the Journal.

Mr. J. MEDD, of Stockport: May I be allowed to ask the mover of the motion, if it would not meet his views, and be quite sufficient, to compliment the editor on the efficiency of the Journal, without referring to the particular period at which the change of management took place? It would really imply something very like a censure upon the previous management, if the resolution were passed as it now stands: and I should oppose it if it were put to the vote.

Mr. CROMPTON: I should be quite content with the alteration.

The PRESIDENT (after a pause, while Mr. Crompton was referring to the wording of his motion): The words "since Christmas" are struck out.

Mr. NOBLE: That alteration will not mitigate my opposition one iota; because the purpose, the reference, and the intention of it are still equally patent. I say that a resolution like that, or any resolution making comparisons between the present state of the Journal and its state at any former period—[Mr. CROMPTON: It does not do that]—is ungracious, and almost an injury, to Sir Charles Hastings and his collaborators at Worcester.

Mr. CROMPTON: I beg to correct Mr. Noble, so far as to say that the resolution, as it now stands, draws no comparison whatever.

The motion of Mr. Crompton was put by the President, and negatived by a considerable majority.

PRESSURE IN CASES OF ANEURISM. BY T. TURNER, ESQ.

Since there is a division of opinion respecting the treatment of cases of aneurism, some surgeons of the present day opposing the attempt to cure by pressure, and trusting wholly to the operation of tying the main artery, it might be interesting to know that a successful case of cure by pressure had occurred in Manchester, under the observation of Dr. Bowman. Mr. TURNER was not furnished with a written paper, nor with full particulars of the case; but he thought the mention of a few facts, showing the manner in which the cure was brought about, would prove interesting to the members. His purpose was to give a few observations respecting a case of aneurism, in which compression of the femoral artery and the upper part of the thigh proved perfectly successful, so that there did not remain a single vestige of the disease. Surgeons are divided in opinion as to whether the successful cases by compression are sufficient to justify its universal adoption in practice, when compared with the success which often results from the operation of tying the artery; and also as to whether the number of cases in which compression has failed ought not to discourage us in having recourse to it at all as a remedial measure. We know well, however, that in many cases, the tying of a main artery is followed by bad effects; in some cases, by mortification of the limb; and in others, by a necessity for amputation. The question, therefore, is this: shall we gain any advantage whatever by the adoption of pressure as a preliminary step to tying the blood-vessel, provided it is necessary to have recourse to the operation, in consequence of the failure of compression? Mr. Turner's experience led him to the belief that, in every case, pressure should be attempted in the first instance; that if it does not succeed in obliterating the artery, so far as is necessary to the cure of the aneurismal swelling, it is productive of good in increasing the collateral circulation, and thereby averting risk of mortification of the limb. In a case where he had an opportunity of observing the changes effected by pressure on the artery and contiguous parts, in a patient at the Manchester Infirmary, on whom he operated, assisted by his colleague, Mr. Wilson, the changes resulting from pressure were such as to show its beneficial effects; and he believed that if the compression had been continued, and if he had not been a restless patient to contend with, the cure would have been most fully accomplished. On cutting down on the artery, at the usual point, and tying the vessel, there was such a confusion of parts, that it was scarcely possible to distinguish one from the other. The sheath of the vessels was thickened to an enormous extent; and when laid open, it was scarcely possible to determine the contained vessels of the sheath, as they were all matted together in the most confused manner. The calibre of the artery was diminished by the thickening of its walls to a very considerable extent. The vessel was tied, and the case terminated favourably. He mentioned it as showing the change that really does take place from pressure; and he repeated, that if it had been continued in the way he should have to relate in connexion with the present case, a perfect cure would have been effected. In every case of aneurism he would adopt pressure in the first instance; and should it fail, the operation of tying the main trunk might, he believed, be had recourse to afterwards with far more chance of a successful issue. The only difficulty resulting is in the performance of the operation; but that may be overcome by devoting a little more care and time to its performance.

In the case to which he alluded as coming under the observation of Dr. Bowman and himself, he (Dr. Turner) requested the patient the other day to give him some few particulars respecting the history and progress of the disease. He would state them in the words of the patient:—

"About the end of February, last year, I felt a pain underneath the knee, which, upon exertion, seemed to extend down the calf of the leg, and to cause a pain, with a lameness and stiffness of the limb. The swelling was at the time small, but there was considerable pulsation in it. It gradually increased in size, and the pain grew worse, until I walked quite lame, and had often to stop in the street when walking quick. All the time the surface of the skin was very hot and dry. I consulted Dr. Bowman on the 15th April."

It appears that he had observed the swelling, and had suffered inconvenience, from the end of February. Dr. Bowman saw the patient; and in a very few days afterwards Mr. Turner was requested to meet him in consultation. The aneurismal swelling occupied nearly the whole of the popliteal space; the pulsation was violent, and extended up to the point where the artery perforates the tendon of the triceps muscle. When pressure being applied to the groin, the pulsation ceased.

tumour gradually subsided. They concluded that these facts were very favourable to a trial of compression. The patient stated, that he always found the pressure to act quicker, and with less pain, when applied to the thigh than when applied to the groin. Now this is a very important fact. In the first instance, an apparatus was used, by means of which the pressure was applied alternately to the femoral artery in the thigh, and at the point where it passes over the body of the pubis. But for this apparatus was substituted a single pad and screw, by which the pressure was vertically directed upon the artery up the upper third of the thigh. This the patient bore for different periods, with different degrees of patience and perseverance. It was found, however, the pressure could not be relaxed, without material injury to the progress of the cure; and it seemed confirmed that the total obliteration of the vessel is not indispensable to the cure of aneurism by compression.

The patient began to attend to business on the 4th of August; the tumour gradually became harder, and the pulsation decreasing, and at length entirely ceased about the 20th of January in this present year.

Mr. NOBLE asked whether the swelling was quite gone?

Mr. TURNER replied, almost entirely. He would (with Dr. Bowman's permission) show any member the case.

The PRESIDENT was sure they must all be much obliged to Mr. Turner for bringing this case forward; for it would serve as the basis of further investigation and experiment.

Mr. SOUTHAM said, that with reference to the reasons which appear to have prevented other parties from succeeding in the cure of aneurism by pressure, he believed that many of them have failed in consequence of the pressure having been applied too tightly. It was for some time considered necessary that all circulation through the artery should be stopped; but the case now brought forward proves that such a thing is not necessary; and the Dublin surgeons, in answer to objections, have pointed out that the amount of pressure necessary to cure aneurism need not stop the circulation entirely. If this is kept in mind, there can be no objection to applying pressure in any case; because, the pressure not being excessive, you do not produce that meeting of the parts which, if the pressure fails, prevents recourse to the operation of tying. In one case where he saw it successful some years ago, there was no necessity to produce any great degree of pain.

Dr. NOTTINGHAM, of Liverpool, said, that it has been contended that the old idea as to the cure of aneurism is incorrect. Several years ago he published an account of a very carefully made *post mortem* examination, where the patient lived some years after the operation, and resumed his occupation; but there was found to be a canal through the aneurism, by which the arterial blood was circulated. In a very considerable number of cases, where the ligature has been applied, that would be the state of things. With regard to the condition of things for tying, after pressure has been applied, there are two important points. There is the mechanical state of things with regard to the state of the parts to which Mr. Turner had alluded; but there is also the question of the vital condition of the lining membrane of the artery, which has not been alluded to. He should be afraid (if one had sufficient opportunities of ascertaining this matter, in many cases where pressure has been applied), that we should find the lining membrane in a condition not favourable to a cure by other means. He had had an opportunity of examining the femoral artery in a case where the attempt to cure by pressure had failed; and he found that the parts were blood-red from the aneurism to the knee. Such a state of things could scarcely be favourable to the results of the application of the ligature.

Mr. TURNER: Might not the excess of pressure be such as to cause the inflammation referred to in the lining membrane?

Dr. NOTTINGHAM: Yes, certainly.

Mr. TURNER continued: In the case related there was no swelling at all remaining, nor could he detect any inflammation by means of the stethoscope. There was no discoloration of the parts.

Dr. NOTTINGHAM believed that, in no case of aneurism that has been properly examined, has it been found that the artery has been restored to its natural position. In some cases it may fairly be said that there is no artery.

Mr. TURNER only meant to say that the tumour is entirely gone, and that there is no pulsation to be perceived. The fact of there being no pulse does not of course do away with the possibility of a canal for the transmission of blood through the artery; because there would be no pulsation when the sac is surrounded by thick coats.

MECHANICAL CONTRIVANCES.

Mr. THOMAS PLATT, of Moor Lane, Bolton, exhibited some improved elastic substances, for bands, belts, etc., which were carefully inspected by several gentlemen.

Mr. W. D. STEVENSON, of Cross Street, Manchester, exhibited a new iron invalid pan. By means of a small handle on the outside edge of the frame, a portion of the mattress was caused to fall into some catches connected with an iron arm, which could be turned out, the piece of mattress removed, and a small pan inserted in the hole by the same process: all this can be done without the necessity of moving or at all altering the position of the patient. By means of a small rack near the head, a portion of the bottom could be raised to any inclination desired, or which might be found necessary for the patient's comfort. Several gentlemen expressed their approval of the arrangements.

Mr. MEDD pointed out to the exhibitor that it would be advantageous to have a second rack for the purpose of raising the feet-end of the bed; as, however weak or languid the patient might be, he might be so placed as certainly to maintain his position when the upper part of his body was elevated, which would not be the case under the present arrangements.

Messrs. J. and W. WOOD exhibited the following instruments:—A portable electro-galvanic machine; an instrument for injecting fluid caustic; an improved utero-abdominal supporter; pessaries made of porcelain, in various forms; a light ladies' elastic abdominal belt, with adjusting strap at the bottom; microscopes, manufactured by Nacet, of Paris; midwifery forceps; and a variety of operating instruments.

CASE OF DOUBTFUL SEX.

While the arrangements of the bed were being explained, Dr. NOTTINGHAM (previous to reading his paper) was exhibiting a cast taken from a person with regard to whose sex doubts had long been entertained. He remarked (as was understood) that many gentlemen in Manchester and in Liverpool had seen the patient from whom the cast was taken; and all had manifested great interest in the case. In rural districts, children born in this state frequently had the misfortune to have their sex mistaken. This individual was taken for a female, and considered as such until the age of sixteen, wearing female attire, etc. At that age, he or she left her native village and travelled to a town more or less distant in Germany, where the case came under the notice of physiologists, and it was made out that the sex was male. The posterior portion of the bladder could be seen, but of course the anterior aspect was wanting, as was also the anterior part of the abdominal apparatus. The upper half of the penis was wanting, as were also the continuation of the urethra, and a portion of the pubic bones. The sexual feeling was very strong, and the testicles were well developed. The man stated that the erection was very complete, and went on to the extent, as he said, of five inches. It was not a little remarkable that this man got married. He was in a hospital in Germany, and one of the nurses took a fancy to him and married him. He had no children by his wife, for which he accounted by saying that the serum passed off at the sides, and did not enter in a straight forward direction.

MALIGNANT DISEASES OF THE EYE.

Dr. NOTTINGHAM read a paper on this subject. He added, that it was originally his intention to have completed the paper by adding some particulars as to cases of different kinds of tumours, but that he had been unable to do so.

VOTE OF THANKS TO THE PRESIDENT.

Mr. MEDD moved, "That the best thanks of the meeting be given to Dr. Black, for his patience and courtesy in discharging the duties of Chairman."

Mr. ROBINSON, of Bolton, seconded the motion; and it was carried by acclamation.

[A number of gentlemen, before proceeding to the Albion Hotel for dinner, were taken by Mr. Hatton to the Royal Manchester Infirmary; Mr. Ferneley, one of the stewards, having kindly offered to point out the improvements that were being introduced into the centre and oldest part of the hospital.]

THE DINNER

Was attended by about forty gentlemen. After the usual loyal toasts had been proposed, the following were amongst those heartily responded to by the members present:—"The Provincial Medical and Surgical Association, and Sir Charles Hastings"; "The Lancashire and Cheshire Branch"; "The late President, R. Bickersteth, Esq."; "The President, J. Black,

M.D."; "The Vice-President, Dr. Dundas"; "The Council, etc."; "The Honorary Secretary, John Hatton, Esq."; "The New Members"; "The Visitors"; etc., etc.

BATH AND BRISTOL BRANCH.

The Anniversary Meeting was held at the Bristol Medical Library, on Wednesday, June 30th, at 3, p.m., when there were present the following members:—John Barrett, Esq. (Bath); J. G. Barrett, Esq. (Bath); J. S. Bartrum, Esq. (Bath); William Budd, M.D. (Bristol); J. B. Burroughs, Esq. (Clifton); Henry Clark, Esq. (Bristol), President; John Colthurst, Esq. (Bristol); James Crang, Esq. (Timsbury); J. G. Davey, M.D. (Northwoods, near Bristol); W. Davies, M.D. (Bath); W. C. Fox, M.D. (Northwoods); James Godfrey, M.D. (Bristol); James L. Green, Esq. (Bristol); Thomas Green, Esq. (Bristol); Thomas Hawkins, Esq. (Bristol); W. B. Herapath, M.D. (Bristol); J. C. S. Jennings, Esq. (Malmesbury); George King, Esq. (Bath); Crosby Leonard, Esq. (Bristol); E. S. Mayor, Esq. (Bristol); W. F. Morgan, Esq. (Bristol); George Norman, Esq. (Bath); George Ogilvie, Esq. (Bristol); Augustin Prichard, Esq. (Bristol); G. Rogers, M.D. (Bristol); Thomas Sawyer, Esq. (Clifton); W. Y. Sheppard, Esq. (Bristol); P. R. Sleeman, Esq. (Bristol); Charles Smerdon, Esq. (Clifton); John Soden, Esq. (Bath); John Smith Soden, Esq. (Bath); J. K. Spender, Esq. (Bath); John Stanton, M.D. (Bristol); R. N. Stone, Esq. (Bath); T. L. Surridge, Esq. (Clifton); J. G. Swayne, M.D. (Clifton, Bristol); S. H. Swayne, Esq. (Bristol); E. H. Sweete, Esq. (Bristol); W. C. Trotman, M.D. (Clifton); James Tunstall, M.D. (Bath); J. G. Wilson, Esq. (Bristol); F. H. Woodforde, M.D. (Taunton). Numerous visitors were also present.

The retiring President, GEORGE NORMAN, Esq., having taken the chair, requested the Secretaries severally to read the notice of the present meeting, and the minutes of the last anniversary at Bath. This having been done, he, in a few appropriate remarks of thanks to the members and compliment to his successor, inducted to the vacant chair HENRY CLARK, Esq., who read the following address.

PRESIDENT'S ADDRESS.

In commencing his address, Mr. Clark referred, in terms of the highest respect for his abilities as a teacher, and his character as a gentleman and a Christian, to the late J. C. Swayne, Esq., Lecturer on Midwifery in the Bristol Medical School, who had, about three years previously, filled the office of President of the Branch.

The subject of the address was an account of some of the practical results which have been achieved by science and art within the last generation. On this point, he (Mr. Clark) felt justified in using the most congratulatory language: when he reflected on the facility acquired of preserving and restoring man's physical frame in its integrity and symmetry, whether it be the trunk, the limbs, or the features; on the improvement that had taken place in the treatment of the insane; on the successful efforts made for the education of the idiot; on the power obtained, through the medium of anæsthetic agents, of alleviating suffering; and on the increasing knowledge of those principles of hygiene, which hold out to humanity happier days and a longer life.

CONSERVATIVE SURGERY. Thirty years ago, diseases of the joints were very imperfectly understood. The sweeping term "white swelling" comprehended all the severe diseases of the different textures of which the joint is composed. Sir Benjamin Brodie did essential service, by separating these affections, and teaching us that the different morbid phenomena must be studied as they appear in synovial membrane, bone, or cartilage; and that, according to the structure primitively or principally engaged, so ought our treatment to be varied. By his judicious counsel, and attention to the dictates of his experience, many limbs have been saved; yet, notwithstanding a knowledge and a skilful adaptation of the best curative means, the integrity of the particular structure has occasionally been destroyed beyond hope of future usefulness, and with danger to life from constitutional irritation. Under such circumstances, loss of the limb was at one time thought to be the only alternative. To the man who has to earn his subsistence by his hand rather than by his head, this sacrifice is incalculably great. How highly, therefore, should we prize the knowledge that, in many instances, resection will suffice. Thus, in cases of diseased elbow-joints, incurable by ordinary means, and heretofore consigned to amputation, the limb may be saved by removal of the heads of the bones; and, for the most part, this may be accom-

plished with little risk to life, and with a rational hope of preserving a useful member. The head of the humerus may also be removed, with expectation of a favourable result.

We are often taught, by the result of accidents, the power that nature can exert to effect repairs in parts which have been seriously injured, and to accommodate them to their altered condition. An instructive instance occurred lately in the Bristol Royal Infirmary, under the care of Mr. Green.

A little girl, about eight or ten years of age, had the head of the humerus, the neck and part of the body of the scapula, and the scapular end of the clavicle, carried away by a gun-shot, with much injury to the soft parts; so that the limb seemed all but severed from the trunk, and appeared to invite its entire separation: yet this limb has been saved, and will even prove a useful member.

Resection of the head of the femur is more difficult, and less likely to prove successful, than is that of the humerus. Nevertheless, there have been several cases which seemed to warrant the operation, and in which it has succeeded.

Similar attempts with the bones entering into the knee-joint have also been made; but the ultimate results are not so encouraging: still, of late, many have proved successful.

But it is in the ankle-joint and the tarsus, where disease so often exists, that the operation of resection has been found so decidedly advantageous. The extremities of the tibia and fibula are removed, and the thick, firm covering of the heel and sole preserved. On this, progression is effected with little help, and with very trifling inconvenience. If Mr. Syme be not the original proposer of this mode, he certainly has been the most successful and frequent operator; and the favourable results of his practice in numerous cases have stimulated others to adopt it. Some years since, when Mr. Clark was travelling through Edinburgh, Mr. Syme was kind enough to show him two or three cases under treatment; and at that period he told him, that many patients, on whom he had performed this operation, were able to walk without difficulty eight or ten miles a day.

In the present day, every finger and toe is scrupulously preserved, which proves to be of any benefit; but not long since they would have fallen with their offending fellows.

It may be said, that the mode of saving limbs by resection was not the suggestion of men of our own day, but was adopted at the close of the last century. This may be true; but its successful application in numerous cases, and its judicious limitation, comparatively, to certain joints, is due to men of the present generation.

To a more recent period belongs the successful mode of removing deformities by subcutaneous section of tendons. Our grandsires, in a few isolated cases, were bold enough to divide the tendo Achillis, dividing at the same time the superimposed parts. Nearly thirty years ago, Mr. Clark had seen that talented and skilful surgeon, the late M. Dupuytren, similarly divide the double tendon of the sterno-cleido-mastoideus, in a case of wry-neck. These operations were, however, painful and hazardous, producing a gaping wound, and causing much inflammation. To Stromeyer we are indebted for that almost painless and bloodless operation, the subcutaneous section, by which we are now enabled to remove deformities, especially of the extremities, which, a few years ago, were thought to be beyond the reach of art. Good results have been effected in this department of surgery, at the Orthopædic Hospital in London.

Great as have of late been the triumphs of surgery, in preserving and restoring the symmetry of the trunk and limbs, the features, which have been marred by disease or accident, have received equal benefit. What could detract more from the beauty of the human face divine than obliquity of the eye? And how readily now is squinting removed! Rhinoplastic operations are more successfully and completely performed, under even disadvantageous circumstances. The mouth has been perfectly restored. Parts have been brought together by parallel sections in the adjacent structure, and by subcutaneous divisions, allowing the intermediate portion to be adjusted in a way not previously thought of. Autoplastic operations are more frequent and successful. Mr. Augustin Prichard has demonstrated their advantage lately in two cases, by restoration of the eyelids.

Perhaps in no instance has this principle of transposing flesh been found so successful as in removing the deformity occasioned by burns. Many are acquainted with the case related by Muller, of America. It was equally characteristic of its great and apparently irremediable character of the deformity, as by its prompt and effectual removal. A similar instance occurred in Mr. Clark's practice at the Bristol Royal Infirmary.

A boy, about twelve years of age, from the effects of a burn received many years before his admission into the hospital, had his chin drawn down near the sternum, his lower lip and the teeth of the lower jaw everted; the saliva continually dribbled from his mouth. The face was greatly disfigured by the traction of the fibres of the platysma myoides, and the tears flowed down the cheek, from the fixed, depressed, and ectropial condition of the lower eyelids. For the relief of this case, Mr. Clark divided the skin from one side of the neck to the other, removed a portion of the hardened cicatrix, and cut the bands of fascia and superficial muscular fibres which tied down the head. A gaping wound was made, about three inches broad, by five or six inches long. Two flaps were then formed, by transfixing the flesh from the side of the neck, and passing the knife downwards over the deltoid to the extreme point of each shoulder. Each of these flaps was about three inches broad, by four or five in length. They were brought across the neck, attached together on the central line by sutures, and were above and below adjusted to the neighbouring parts. The whole was then covered with cold water dressing. Union became perfectly established, and the deformity was at once greatly removed, with the probability of time aiding the restoration.

MENTAL DISEASES. We have not expended our energies in our attempts to improve man's physical frame. The treatment of the disorders of his mind has alike undergone a beneficial change.

There was a time, and that lately, when the maniac's emotions were tried to be calmed by opening his veins; and his passions were attempted to be controlled by manacles and confinement. Violence was overcome by rude force; and the rule of terror was the chief moral government. How different the case of the maniac now! and how much happier the result! The clanking of the chain has been but rarely heard, since Pinel unshackled fifty-three with his own hands. Restraint of any kind, in its special signification, is seldom had recourse to; blood is not recklessly spilt, under the guise of remedial agency, but a moral treatment, combined with appropriate medicinal means, is adopted, founded on a knowledge of the habits, tastes, and peculiar talents of the individual; so that the disturbing forces may be kept passive by the activity of other faculties. The mind, being thus pre-occupied by subjects judiciously selected, is kept from dwelling on those disordered associations which had dethroned the judgment. Kindness has taken the place of severity; threatening has given way to entreaty; and the calmness and amiability of the attendants have struck a chord of sympathy in the minds of those who previously brooded over nothing but vengeance and misrule. Our private asylums are no longer viewed as prisons, or mere houses of safety, but as comfortable homes, where nothing that can ruffle the passions is suffered to intrude, and every suitable provision is made for the employment of any special talent. In them, with appropriate medical treatment, that kind of training and moral education is adopted which is most likely to restore the healthful balance of the mental faculties.

The perusal of accounts of the management of some of the extensive public institutions in this country, or in France, must give rise to feelings of the highest gratification, especially when we compare their state with that of the asylums of the last century. Mr. Clark referred to the changes introduced in Hanwell Asylum, under the guidance of Dr. John Conolly, formerly the conductor, and now the consulting physician. See him (said the speaker) pass fearlessly among the hundreds (952) of unshackled inmates of that asylum. Listen to the voice of kindness, that immediately obtains a response. Observe the calmness and firmness of the attendants in the discharge of their duties. Go into the banquetting-room, and witness the general joy evinced by the lunatic guests on their festive occasions. Follow them to their dormitories, and notice the quiet repose that succeeds; and you will be struck and delighted with this peaceful result. Rise with them in the morning; and you will find that these numerous occupants have each their appropriate engagements; and that, while the utmost liberty is permitted them, every destructive agent is withdrawn, and the greatest watchfulness exercised. Follow them, day by day, through these active scenes, to the termination of the week; and the Sabbath begins with attention to religious exercises, when the seriousness and devotion of some would afford a fitting example to many who call themselves sane.

Thus, by establishing order and regularity, introducing active occupations, exercising the mind agreeably, ruling by kindness and entreaty, overcoming violence without angry efforts, and the judicious use of medicinal means, our asylums have be-

come pleasant domiciles, and those favourable results have promptly been experienced which the old system of heroic medical treatment, threatening, and restraint, could never have effected.

There are doubtless evils yet to be rectified; and surely that must be considered one, which allows lay commissioners the power of interfering with the medical management of the inmates of asylums, and of dictating the propriety of their admission, and the appropriate time for their discharge. This duty should I think, be assigned to a professional supervisor; while the lay visitors should confine their attention to seeing those laws enforced which relate to the general economy of the establishment. Pseudo-philanthropy has of late been too apt to exhibit itself in the officious discharge and protection of the maniac; while to their more sane neighbours no kindly feelings have been cherished.

As proof of progress in the treatment of the insane, may be recounted the establishment of schools in various public asylums, and the pleasing fact that, in 1845, in the Bicêtre at Paris, of eight hundred lunatics, two hundred were receiving instruction. Success has also crowned the exertions made of late to benefit the condition of idiots, by strict attention to their *bodily health*, arousing the dormant senses, and fanning the feeblest spark of intellect. Many instances are recorded, in which the idiot has been raised from an animal, or almost vegetable life, to the position of humanity.

The name of Guggenbühl, a Swiss physician, is familiar, from his having distinguished himself by devoting his energies to the cure of cretinism. For the welfare of such poor creatures, he is dedicating his life and powers, regardless of all difficulties, in a solitary spot, on a high mountain, near Interlachen. He has an assistant, who has had experience in the instruction of the deaf and dumb; and Sisters of Charity act as nurses. Some of his patients have been the most degraded of their class, and evinced scarcely more than the functions of vegetative life—the voice more animal than human; the ear inattentive to any ordinary sound; the eye fixed on no object; the taste and smell so depraved as to allow them to receive and swallow the most loathsome food; and the limbs unequal to any steady movement. The assimilative powers have been assisted, and the muscular system strengthened, by tonics, baths, and friction. The ear has been roused to the influence of sound by a speaking trumpet; and the eyes solicited to fixed action by figures made by phosphorus on the wall, in a darkened room. The functions of the body being somewhat restored, and the senses rendered capable of conveying impressions to the brain, a higher order of education has been commenced, which, in many instances, has proved successful. Man wields a vast moral power, for good or for evil. If he speak a wise word, it is well; if he perform a good act, it is better. Our words and actions have an undying influence. Example, however, surpasses precept. Little, perhaps, did Dr. Guggenbühl think, when pursuing his modest but meritorious labours, in a sequestered spot, apart from the "noise of cities", and the hum of men, that he should attract the attention of a traveller (the Rev. Dr. Andrew Reed), who should return to England, actuated with a kindred spirit, and arouse his countrymen to the importance of copying the example of the Swiss physician; and that two institutions should soon be opened, affording relief and instruction to two hundred and fifty-six idiots; and that, after the lapse of another short period, an institution should be established, under the patronage of our Queen, the foundation-stone of which was laid by Prince Albert only last week, the funds already subscribed towards which amounted to £10,000. This institution will most probably awaken public attention to the claims of a very helpless race, and be followed by the establishment of other similar asylums. Thus, the unostentatious example of one devoted man, pursuing his occupation on a retired spot on a Swiss mountain, may be copied throughout Europe, and the idiot part of our population never more be abandoned as incurable or incapable of instruction.

ANÆSTHESIA. Having gained power over the evils which afflict man in his body and mind, we have further learned, within few years, how to assuage his pain. Mr. Clark here referred to the discovery in America of ether as an anæsthetic agent; and to the subsequent discovery of chloroform for the same purpose, which rewarded the untiring energy of Dr. Simpson of Edinburgh. The experience of six years has taught us that the fears at first expressed on the subject of anæsthesia were too great; that, if lives be occasionally perilled or lost by its administration, a larger proportion are saved by its adoption, as there are numbers who,

would it, would die from the mental or the corporeal shock of a severe operation.

We have not only found an agent capable of subduing pain, but one of surpassing power in various derangements of the nervous system. In tetanus, chorea, infantile convulsions, and other obstinate spasmodic diseases, that have resisted all previous treatment, it has proved occasionally an effectual remedy. Mr. Clark suggested the propriety of renewing the attempts to cure tetanus by the section of the nerve leading to the injured part, or by the entire removal of the latter, especially when it can be accomplished without the loss of an essential member; for, unless tetanus be the result of accumulative toxæmia, of the nature of which poison (if it exist) we are quite ignorant, it must be the correct practice to endeavour to remove the exciting cause of irritation, and to lower the reflex irritability. The former has been often attempted without any anæsthetic agent, but with too little success to warrant its further adoption; but, under chloroform, the probabilities of a favourable issue are certainly increased. Without it, another shock is inflicted upon the depressed and irritable nervous fibre; and the injured part must be removed during spasm and extreme suffering. With chloroform, we achieve the double object of removing the source of irritation without inflicting pain, and lowering the reflex irritability. Thus the chances of success are manifestly increased.

A few weeks ago, Mr. Prichard, acting in concert with all the other surgeons of the Bristol Royal Infirmary, removed, by Chopart's operation, part of the foot of a young man, who was the subject of acute tetanus from an injury of two of his toes, and in whom the symptoms were so rapidly developed, that no other probable chance of relief could be entertained. He, however, survived the operation only twelve hours. No alleviation followed the operation, except a little more capability of swallowing. In this case, it was attempted as a *derrière ressource*, truly a *remedium anceps*: and the failure in this instance ought not to militate against further trials.

In a little while after this, another case occurred. The patient had a crushed great toe. Trismus had commenced, when it was decided to remove the whole of the injured part by sawing through the metatarsal bone of the toe. This was done under the full influence of chloroform. The pulse fell from 110 to about 80; and the spasm was mitigated for two or three days, when opisthotonus began, and was again subdued by chloroform, which was repeated, as often as the spasm recurred, for many successive days. When it was apparently entirely overcome, pneumonia occurred, of which the patient died on the fourteenth day after the operation.

A third case then happened; it was the result of a severe lacerated injury to all the toes in a young man. Here the spasm was confined to the limb, which was frequently drawn up by a tonic convulsive effort; the countenance appearing very anxious, and the pulse being rapid. The whole of the toes were removed, under chloroform, at the tarso-metatarsal joints; and some opium was administered. The spasm was stayed in the limb; nevertheless, the next day, he bit his tongue from a convulsive snap of the jaw. This had not recurred; and, at the time of Mr. Clark's address, the patient was progressing favourably; but it was only the fourth day after the operation.

These cases will be shortly published in detail.

We must not entirely forget that, like all things terrestrial, anæsthesia is not an unmixed good. The rose has a thorn. Twenty-five deaths are recorded, and these are not half that have occurred since its introduction. True it is that, if the drug be good, and it be cautiously administered, and the symptoms carefully watched as they pass from excitement to deranged function, and thence to stupor and coma, and we here arrest its exhibition ere the respiration or heart's action become seriously involved, very few such instances will happen. Nevertheless, we must be aware that these successive stages are not always followed in this precise order. The ultimate link of the chain is suddenly seized. The citadel falls before the outposts have had timely warning.

HYGIENICS. Cheering it is to mark the means now adopted for the preservation of the body in its completeness and symmetry, and to observe the successful efforts that are made in restoring the mind and lighting up the latent sparks of intellect, and the power we possess of rendering many free from suffering; but it is a still greater pleasure to notice the great impulse which has of late been given to the promulgation of those principles which are calculated to *prevent* disease, to add to man's comfort, and

lengthen his days, by making *our cities more pure, and rendering our fields more fertile.*

By late fiscal regulations, the blessing of light is not so much restricted as heretofore. The dwellings of the poor and the rich may now share it more equally. It is not, however, yet sufficiently appreciated; and the axiom cannot be uttered too wide or too loud, that,

"Where the sun does not come,
The doctor does."

The value of pure air, and of a free supply of it by ventilation, is becoming better understood. The construction of model houses and rural cottages must tend in this respect to amend the condition of the labouring population.

The readiness with which water is now obtained in our large cities, and conveyed to the houses of the poorer classes, and the public baths and wash-houses that have of late been established throughout the country, must prove of essential benefit; for we are told that "cleanliness ranks next to godliness."

Light, air, and water, are God's gifts to man. He gives them bountifully. They are all essential to man's welfare. May we prize them more, and take care that, in our dwellings, we do not shut out the cheering sunbeams; that we admit the air free and untainted; and that we have a supply of water pure and copious. To effectually obtain these important advantages, the drainage of our cities must be made more complete. Happily, the public attention is now directed to this object, and with great probability of its being accomplished; since it has been clearly shown that our sewage ought to rank among our natural resources; and that what may be destructive in our cities may be made regenerative in our fields; proving the truth of the remark quoted by a great living statesman, that "dirt is only a good thing in a wrong place."

Various means of deodorization have been proposed and are now adopted; and we learn that one patentee has secured by lease, for the city of London, the sewage flowing into the Thames by Puddle Dock, Paul's Wharf, Dowgate, and Lower Thames sewers; and that, from these sources, he will be enabled to obtain thirty tons per day of a dry deodorized residuum, or about ten thousand tons per annum; valued at about £20,000. The town of Leicester has recently effected like arrangements.

This hygienic progress is not confined to our cities. Science has lent her active aid to agriculture; and the country is generally becoming more *healthful and productive*. The right principles of rural drainage are being widely promulgated, and the small cylindrical pipes, buried deep in the soil, are no longer pointed at with derision as "Machi's pencil-cases", but are found to render good service. Until of late, the object of drainage in the country appeared to be to convey away the waters that descended, and not the water that ascended. It was forgotten that the office of the rain which came from heaven and fell upon the surface of the earth, was to fructify; that it brought with it the materials of increase; while the water that burst up from the soil beneath was void of those qualities, and served to keep the land *cold and barren*. The depth at which the pipes are now placed is measured by feet, not by inches. The effete water does not rise beyond the level at which they are placed. The ground above, though ever so *tenacious*, becomes at length porous. It is first dried by the action of the sun, and the withdrawal of the stagnant under-water; then cracks take place, which extend from the surface down to the pipes; and the worms are diligent and successful borers. By these channels, fissures, and pores, the fertilizing rain and warm air have access to deep parts, passing through clay and earth that before they never permeated. Previously, by capillary attraction, the under-washed land water was carried upwards, saturated the earth, and, by preoccupation, prevented the absorption of the fertilizing showers; while, in other soils, the clay was so *tenacious* that the rain which fell upon it passed over its surface and ran off by the rivulets, to pass away into the rivers, without dispensing the benefits which the Almighty designed. By the means of deep laid pipes, rendering the soil more accessible by its porosity to the action of light, air, and rain, its fertility is *doubled*, and *man's wants, therefore, are better supplied*. The same object is facilitated by altering the temperature of the land, and thus it is rendered *not only more fertile but more healthful*. There is an anecdote of an agriculturist who was often seen with his gait coat, but after a time was as frequently seen without this and. He had, in this transition period, "*thorough drained*," his land; and the result was, that he considered it *quite a warmer*.

In this great agricultural theatre, *new lessons* are in physiology and pathology; and old truths, *so* fit to man, are being confirmed. *Hence it is that*

taught the importance of giving an adequate supply of appropriate food during the infantile period; that, if we suffer it to pass without attention to this law, defective vitality is stamped on the organization, and remains throughout the whole of the future life.

In this instructive field of investigation is demonstrated, on a large scale, the double object of food; viz., for *nourishment and fuel*. That substances containing nitrogen are for flesh-making; while starch and sugar, and other non-nitrogenous articles, are destined to give heat. The gluten of the one is transformed into muscle and blood, the carbon of the other is burnt up by the oxygen inhaled; while warmth, by this combination, is emitted, and carbonic acid exhaled. True it is, as Professor Playfair most graphically states, that the body of the animal may be regarded as the furnace; the carbonaceous food the fuel; the excrement the ashes; and the gases that escape from the mouth the same as those which escape from the chimney. Animals seem almost to know by instinct the special food required. Hence it is almost useless to give them chaff till the cold weather comes on. As the winter deepens, they eat it with avidity; but in spring they gradually leave it off, and then actually refuse it: just, in fact, as we light up our fires at Michaelmas and extinguish them in May.

Again, we are taught by our treatment of animals how much temperature has to do with maintaining condition. If our poor are clothed and housed badly, they require more food. One fourth less nutriment, with adequate shelter and bodily covering, will be requisite to maintain a healthier state than when deprived of these advantages. Hence the Russian takes train oil, and the Eastern his rice; the difference of temperature of necessity causing this variation in the quality as well as in the quantity of the food.

Here, also, we are daily learning the astonishing power of hereditary influence. Whether it be horn or hair, fat or flesh, either can be modified in quality or proportion at the will of the breeder. Nature is so plastic under scientific management, that fat can be laid on either within or without the body, as is most expedient. Flesh can be developed on parts where it is most required; symmetry can be handed down from one generation to another, and even temper transmitted. How invaluable is this lesson, if it be duly considered in reference to the formation of matrimonial alliances.

Mr. Clark then alluded to the great saving of human life, which had been effected by a knowledge of disease in the cow and its transmission to our species. Had not a Jenner lived, millions would have perished ere life had scarcely dawned. By the direful scourge of small-pox, a funeral pile of eighty thousand would have been raised annually in Great Britain alone; and when we look through the wide world and contemplate the ravages that this disease might have made, the thought may well affright us. If then the chisel and the marble fail to adequately record the memory of the man who stayed this plague, there is a colossal monument remaining in the millions of lives preserved, that will louder and still louder proclaim the name of Jenner, when the columns of brass and the pillars of stone, that tell of the warrior's fame, shall have fallen into decay.

Other discoveries of a similar kind still wait us: indeed, experiments of surpassing interest are now being made in this country, France, Holland, and Belgium, with cattle; and may prove pregnant with benefit to the human species. Mr. Clark alluded to the supposed discovery made by M. Willems, a Belgian, for the prevention of a most fatal disease among cattle (pleuro-pneumonia) by inoculation. M. Willems has taken the secretions from the lungs of a diseased animal, and inserted it in the tail of a healthy one. It has then produced local disorder, with some constitutional disturbance; and ever after there has been immunity from pleuro-pneumonia. The subject is undergoing the most searching investigation. The commission appointed by the governments of Holland and Prussia have given a favourable report; but Professor Simonds, who was selected in this country to examine the question thoroughly, has come to an opposite conclusion.

Mr. Clark would ask, whether we have not cause for exultation this day, since it is true that comparatively in a few short years we have done much more than our ancestors to preserve and restore man's physical frame, to correct the disorders of his mind, and to light up the very embers of intellect, to save him much suffering, annihilate agony, to prevent disease, to add to his comforts and prolong his life. He could just imagine a disciple of Malthus to be frightened at this picture, and pensively brooding over it, to say. If the infant be saved, and the

mother be spared—if disease be prevented and life be prolonged—shall we not jostle each other, and will our island be adequate to the required increase of food? Happily there is an Almighty, one who watches the fall of the sparrow, and clothes the lilies of the field, who is not unmindful of the wants of man, whom He has formed after His own image. He who "weighs the mountains in scales", and the hills in a balance, and metes out the waters in the hollow of His hand, He has storehouses in the air above, in the earth, and in the deep, yet to unlock; and at His set time He can call off the people to the far east and the west, by shewing them hidden treasures; precious metals for ages unheeded under their feet; and can direct them to a rocky isle of Peru almost unknown and uninhabited save by wild fowl and screaming birds; and in that desolate situation He has founded a garner of the richest fertilizing materials waiting the demands of an increasing population. No sooner has the fiat "Increase and multiply", been accomplished, than this storehouse has been opened to replenish the earth. We need not, however, travel to distant isles to discover these omniscient marks of design and beneficence. On our own coast we have found vast materials, which were entombed in the bowels of the earth ere the waters covered it—the coprolite, the fossil dung, and remains of gigantic antediluvian lizards, rich in phosphate of lime, a most fertilizing manure. All these teach us in a language that all nations can understand—that from the reptile which crawls on the earth, to the bird that flies in the air, all movements are directed by an unseen but almighty hand, and that for the benefit of His creatures.

[We regret that we have been obliged to curtail the report of this eloquent and instructive address. EDITOR.]

Mr. COLTHURST, Secretary, presented the

REPORT OF THE COUNCIL.

As it has become the well understood duty of your Council to give at each Annual Meeting some account of their stewardship, and to call your attention to any subject that may seem to affect the well being of our Society, there is, perhaps, some fear lest the frequent recurrence of this period should induce indifference. This ought not to be; the review of the events of a past year can never be unimportant. Nor should it ever be permitted to dwindle into a point of routine, since it involves that most pertinent of inquiries—Have we been well occupied? has our time been well or ill spent? Your Council do not consider that you need shrink from the inquiry, as they can point with pleasure to the large attendance at your Quarterly Meetings, to the ample supply of papers and cases which have sustained the interest of those meetings, and to the beneficial discussions and conversations connected therewith.

The COMMUNICATIONS made have been as follows.

On October 7th:—

Dr. WM. DAVIES. A Case of Abscess of the Right Ovary terminating in Rupture into the Peritoneum, and Death from Acute Peritonitis.

Mr. PRICHARD. A Paper on Extraneous Bodies removed from the Eye.

Mr. COX. A Paper on the Co-existence of Gonorrhœa and Syphilis.

Mr. JOHN BARRETT. A Case of an Infant exposed, in which he had employed Mr. Bloxam's test, for deciding whether the child's Lungs had been inflated naturally or artificially.

March 24th, 1853:—

Mr. HINTON. A Paper on Internal Strangulation of the Bowels.

Mr. MASON. A Case of Congenital Occlusion of the Duodenum.

Mr. JENNINGS. A Paper on the use of the Hot Bath in Suspended Animation.

Dr. SWAYNE. Two Cases of Frontal Presentation.

Dr. W. DAVIES. An unique Case of Cerebral and Spinal Apoplexy.

Dr. C. EDWARDS. A Paper on the question, as to whether an excess or a depraved state of the Gastric or Pancreatic Juices can decolorize the Bile and simulate Functional Disease of the Liver.

Mr. NORMAN. A Report of a Post Mortem Examination of a Case of Extensive Prostatic Disease.

The December meeting was omitted, in consequence of two special general meetings being held on a subject which is too fresh in the painful remembrance of all the members, to require any further mention.

INCREASE OF MEMBERS: THE JOURNAL. It is gratifying to the

Council to report that our numbers have increased during the last year. Your Council has reason to believe that this increase has mainly depended upon the change in the plan, etc., of the JOURNAL. This change was determined on at the annual meeting at Oxford, but through some supposed irregularity in the proceedings, was likely not to have been carried into effect, had not your Council held a special meeting in Bath, on September 3rd, 1852, at which Mr. Sheppard, the central Secretary, attended. Your Council then protested against the central Council at Worcester attempting to override a vote of the general Association, without calling a special general meeting. Your Council took this step without at all wishing to enter into the merits of the proposed change, but with a view to avoid so dangerous a precedent as would be presented by so irregular a course on the part of your central Council. And it may be well to notice here, that while the present mode of publishing the JOURNAL weekly instead of fortnightly considerably increases the demands upon the finances of the Association, it remains to be proved whether the members generally take so much more interest in their own Journal as to make it a favourite with the profession; because, should they not do so, and should not our numbers still materially increase, it must not be supposed that we can continue to enjoy at the price of £1:1:0, that which is supplied to others at the very different charge of £1:10:4.

THE POLITICAL QUESTIONS in which we have been particularly interested, are the Income-tax, the Medical Reform, and the Vaccination Bills.

The only modification of the Income-tax that has been obtained, is the very trifling one, that we may be rated upon the average of three years instead of the last.

The Bill introduced by Lord Lyttelton for effecting compulsory Vaccination is one that deserves attention, since it is very questionable whether the beneficial and salutary discovery of the immortal Jenner would not be rendered odious and unpopular thereby, and the prevention by general and complete vaccination of the recurrence of small-pox be still further endangered. Your Council further consider that the Bill is objectionable on account of the amount of ill requited labour thrown on the medical profession, seeing that no measure can be effectual which does not secure the zealous cooperation of that body.

As to the progress made in the never failing and ever wearying subject of medical reform, your Council, although fully aware of the efforts made, and the glowing anticipations of early fruit held out by the Central Committee appointed at Oxford, cannot promise much. They find no chance of any measure being carried that is not taken up by the Government; they find the Premier and the Home Secretary, upon being told that we are unanimous, promising to introduce the subject, and immediately afterwards they find the same parties backing out, as upon inquiry they learn the unanimity to be a fiction. How can it be otherwise, with the College of Surgeons of England and the Medical Faculty of Glasgow directly opposing, our own South-Western Branch strongly condemning, and the College of Physicians of London only upholding the Bill, whilst that College makes a great stride for itself, and obtains its long-desired charter, which very materially enlarges its power, and extends its influence over the whole of England? The only probable result of this parliamentary session will be this Charter. Your Council are fully alive to the extreme difficulties besetting the question, arising out of what may be termed the vested interests of the nineteen different sources from which licenses to practice may be obtained, as well as from the extreme laxity with which any individual, qualified or unqualified, has been permitted to style himself doctor or surgeon, as the humour or convenience of the moment dictated.

Your Council do not propose any special course for adoption; but they are anxious to express their belief, that no better regulation of the medical profession can be effected while the present utter want of uniformity in professional qualification prevails; nor can the medical profession hold a fitting position in the body politic until there be a system of registration, by which men who have been properly educated, and who possess a legal qualification to practise, may be distinguished, not only from ignorant and dishonest pretenders, but from those who, having undergone a slighter education and a slighter test, still assume the same title.

BENEVOLENT FUND. Your Council pass with much pleasure from the consideration of these subjects to the more grateful one of the Benevolent Fund, which they are thankful to know is not neglected by you, whilst it pursues its sphere of unobtrusive usefulness under the guidance of its most industrious and warm-

hearted advocate, Mr. Newnham. Your Council also deem it worthy of notice, though it is not so immediately connected with your Association, that the more aspiring scheme of Mr. Probert has, during the past year, not only met with great pecuniary success, but with royal favour,—the Prince Consort having graciously signified his intention of laying the foundation stone of the new College at Epsom, on the 6th of July next.

OFFICERS. Before closing their report, your Council beg to state the result of the ballot for eight new Members of Council, in the room of those retiring by rotation, viz.—*Bath district*: Messrs. Crang, Colborne, George, and Godfrey. *Bristol district*: Messrs. Morgan, Green, Estlin, and Ogilvie.

Your Council have also to notify to you the retirement of the Bristol Secretary. He has for some time past intimated his wish to be relieved of his official responsibilities, in consequence of being unable to give that attention to the duties of his office which he considered it to merit; he has, however, retained it until your Council could propose to you a successor, which they now do in the person of Mr. Crosby Leonard, of whom your Council will only say that they believe he will be valued by all, his private worth and professional attainments being highly spoken of by those who have had the best opportunity of observing him.

It was moved by Mr. GODFREY, seconded by Mr. JOSEPH BARRATT, and resolved unanimously, after a few remarks from Messrs. King and John Barrett on the Medical Reform and Vaccination questions, that the Report of the Council be adopted.

VOTES OF THANKS.

A vote of thanks to the retiring President, GEORGE NORMAN, Esq., for his zealous and efficient services to the Association during the past year, was, on the proposal of Drs. TUNSTALL and SWAYNE, carried by acclamation.

Mr. NORMAN acknowledged the gratification that such kindness from his professional brethren always gave him.

It was then moved by Dr. HERAPATH, seconded by Dr. DAVEY, and resolved unanimously, that the best thanks of this meeting are hereby given to the council and secretaries for their constant attention to the interests of the society during the past year, especially to those gentlemen who now retire by rotation, viz.: Messrs. Crang, Colborne, Godfrey, George, Estlin, Kay, M.D., Morgan and Ogilvie.

ELECTION OF OFFICERS.

Mr. CRANG proposed JOHN SMITH SODEN, Esq., as President-elect, pointing out his long attachment to the Association, the general esteem in which he was held, and the eminent position he had attained, as admirably fitting him for that honourable office.

Mr. MORGAN seconded the proposition; which was carried unanimously.

Mr. SODEN accepted the duty, stating that although he had almost withdrawn from professional pursuits, yet he would do his best to meet the wishes of his brethren.

Mr. COLTHURST was desirous of moving the next resolution, as it would enable him to thank them for their continued kindness to him during his five years of office. He must acknowledge that he could not sever himself from his post without a considerable feeling of regret. It was necessary however to do so, as he knew that he could not give the time which the office merited. He was therefore about to propose the reelection of Mr. Bartrum, whom they valued too highly to require any additional encomium from him, although he might be permitted to speak of him as his able and agreeable colleague; and then to propose for election with him Mr. Crosby Leonard, a gentleman well known at the Bristol Royal Infirmary for his devotion to his professional pursuits, whilst his industry, punctuality, and amiability, rendered him a general favourite.

Mr. CLARK, although in the chair, must take leave to second this proposition, as he could not allow Mr. Colthurst to name a successor to himself without expressing the regret the society felt at losing his services. If, however, Mr. Colthurst could not continue, he had long known Mr. Leonard, and believed him to be in every way suited to fill the vacancy.

MESSRS. BARTRUM and CROSBY LEONARD were then unanimously elected Secretaries.

A vote of thanks to the Medical Library Society for their liberality in permitting the use of their room, was, on the proposition of Mr. BARTRUM and Dr. WOOLHOUSE, unanimously recorded.

After conversation on the Vaccination Bill of 1852, it was decided that the two councils should meet on the 15th of July next.

the bill; and subsequently, on behalf of the society, present to Parliament such petitions thereon as may seem to them necessary.

COMMUNICATIONS.

Dr. DAVEY read a paper "on the Physiological Uses of the Ganglionic Nervous System."

Dr. HERAPATH exhibited a specimen of an aortic aneurism which had opened into the trunk of the pulmonary artery, producing sudden death.

Dr. SWAYNE exhibited a preparation of an infant, where, from the absence of a diaphragm, the abdominal viscera had thrust themselves into the thorax, compressing the lungs and displacing the heart. The case occurred in the practice of Mr. Crang.

This case is published at p. 589 of the ASSOCIATION JOURNAL for July 8th.

A vote of THANKS to THE CHAIRMAN for his attention and urbanity was carried by acclamation.

THE DINNER.

The members then adjourned to the White Lion Hotel, where, under the spirited presidency of Mr. Clark, honoured by the presence of the Mayor of Bristol, and the Rev. Mr. Knight, rector of St. Michael's, upwards of forty gentlemen spent a very agreeable evening, fully impressed with the social as well as the scientific advantages of the ASSOCIATION.

MONMOUTHSHIRE AND SOUTH WALES BRANCH: ANNUAL MEETING.

The second Annual Meeting was held on Wednesday, the 6th inst., at Chepstow. The members of the medical profession on their arrival in the town were entertained by the President, TREVOR MORRIS, Esq., M.D., at his residence. An elegant breakfast was provided, and many gentlemen partook of the hospitality extended towards them.

The meeting was held in the Public Room, Bank Buildings. Among those present were—John Audland, Esq. (Tintern); F. C. Batt, Esq. (Abergavenny); G. Gwynne Bird, M.D. (Swansea), President of the ASSOCIATION; B. M. Bradford, Esq. (Chepstow); George Cherry, Esq. (Caerleon); G. Davies, Esq. (Merthyr Tydvil); Andrew Davis, Esq. (Pentwyn); W. T. Edwards, M.D. (Cardiff); J. Essex, Esq. (Pontypool); T. Evans, Esq. (Cardiff); W. P. Evans, Esq. (Swansea); T. King, Esq. (Chepstow); — Lawrence, Esq. (Pontypool); W. H. Michael, Esq. (Swansea); W. W. Morgan, Esq. (Newport); Edward Robathan, Esq. (Risca, near Newport); R. Stack, M.D. (Newport); S. H. Steele, M.D. (Abergavenny); Charles Sylvester, M.D. (Cowbridge). There were also in attendance:—The Rev. J. B. Gabriel (Chepstow); the Rev. G. Williams (Chepstow); Fenton Hort, Esq. (Chepstow); W. T. Colville, Esq. (Wye Cottage); — Colville Esq.; W. E. Toye, Esq.; W. Martell, Esq.; A. B. Savery, Esq. (Hardwick Lodge); John Smith, Esq. (Hardwick); J. L. Baldwin, Esq.; E. Baldwin, Esq.; D. G. Thomas, Esq.; and Rees Davies, Esq.

The proceedings commenced by Dr. BIRD, as President for the past year, returning thanks for the kindness and consideration which had been accorded him during his term of office.

Dr. MORRIS, before he took the Chair which had been vacated by Dr. Bird, begged to move that a vote of thanks to that gentleman for his services during the past year be entered upon the records of the Association.

The motion, having been seconded by Dr. STACK, was carried amid applause.

The PRESIDENT (Dr. MORRIS) then proceeded to deliver his address, which was listened to with the greatest attention, and frequently interrupted by warm expressions of approbation.

PRESIDENT'S ADDRESS.

GENTLEMEN,—The opportunities for reunion presented to us by the meetings of the Branch Societies of the Association, must afford peculiar pleasure to the members of a profession whose arduous and engrossing duties generally fix them throughout the year to particular localities, and prevent them from participating in the ordinary facilities of intercourse enjoyed by gentlemen of other pursuits. In order to remove this disadvantage, the Monmouthshire and South Wales Branch of the Provincial Association has been formed; and at this, its second anniversary meeting, over which you have called me to preside, I greet you with a cordial welcome, in full trust that this reunion may promote those feelings of good will, confidence, and brotherhood, which should characterise gentlemen engaged in our philanthropic

calling. By your kindness I occupy the distinguished post I now fill; and if I should be found to perform its duties imperfectly, I must throw myself upon that indulgence, which originally selected me for this honour. I am conscious of succeeding a President who performed the duties of his office with that high talent and urbanity which are well known to distinguish him in all the duties and intercourse of life; and while I feel a just pride in following in his honoured steps, I am rendered only the more sensible of the responsibility of the office which I am called upon to discharge.

It is with much satisfaction that I welcome my medical friends to the ancient Saxon town of Chepstow, celebrated in our annals for the industry, valour, and loyalty of its inhabitants, and in song for the enchanting beauty of its scenery—its woods and cliffs, soft slopes, and winding river. It may perhaps be said truthfully that all the elements of the picturesque and the beautiful seem to have combined, to make this neighbourhood a rich illustration of the fine and varied landscape of our country. The visitor will admire the princely castle where the Fitzosbornes, the Strongbows, the Mowbrays, and the Herberts successively held lordly rule, and mustered their men-at-arms, for feats of the battle-field or for defence, and the monastery where the Benedictine fathers once counted their beads, and chaunted their vespers. Both now exist in venerable ruins, reminding us of the departed chivalry of our past history, and shading with a solemn sentiment the lovely landscape on which Nature seems to have bestowed with a liberal hand her choicest attractions.

I recommend my friends to pay a visit to the interesting relic of feudal grandeur, Chepstow Castle, situated with singular beauty on the edge of a lofty cliff, with its walls clothed with ivy and its embattlements dismantled. From its hall the celebrated Richard Strongbow set out to make the conquest of Ireland; here a band of brave and loyal troops held the fortress against the insurgent Parliamentarians, and the iron hearted Cromwell was compelled to confess a defeat. Eventually, indeed, the Parliamentarians took possession; and those halls which had been graced for centuries with the flower of British chivalry, owned the haughty and severe Lord Protector for their master. A round tower in the first court is memorable for having been, for twenty years, the prison of the regicide, Harry Martin.

Chepstow church contains the tomb of this stern republican. We are not without other records of Harry Martin; an interesting portrait of him, said to have been painted by Walker, an artist of eminence, in the reign of Charles II, being in the possession of my worthy and highly esteemed friend, Mr. Lewis, of St. Pierre, who resides in one of the most charming seats in this neighbourhood, where the classically grand in execution and the rich and beautiful in nature unite to please the purest taste. The church is a portion of what was formerly a Benedictine monastery; and it cannot be denied, that the founders exhibited their usual taste in the selection of a spot for their habitation. Its western front, with its round arch and zig-zag moulding, is an admirable and rare specimen of the Saxon or early Norman era; but the structure also exhibits decorations of a later period.

Moynes Court, Matherne, and Caerwent, are equally deserving your attention. The elegant iron bridge which now spans the Wye has replaced a more ancient structure which had many interesting associations for the antiquary; but the bridge and its memoirs are swept away, and we must console ourselves with the utilitarian reflection, that although we may have lost something in the picturesque, we have gained in suitability and mechanical elegance of structure. The march of modern ideas has reached even the quiet, time honoured town of Chepstow, and threatens to bend our predilections to its practical and unromantic tastes. The genius of the place will, I have no doubt, struggle hard against the invaders. Connected with this bridge, I may mention that the tide rises here with extraordinary rapidity, and mounts as high, on the average, as fifty feet. The archaeologists of the Association will find pleasure in visiting the Roman encampments, several of which are to be found in this neighbourhood, and one at Southbrooks, which is very remarkable. But the sovereign charm of our scenery is the beautiful and winding Wye, with its toppling cliffs, its surrounding woods and dells, its green meadows and wild copses, its peeps of orchard ground, and cottage gardens, constituting "a most living landscape", crowned with the far famed Tintern Abbey. This prospect poets have delighted to sing; here Wordsworth, Coleridge, and Southey, tutored the eye of taste, and penned their poetic inspirations. Returning to the scene of his youthful delights, Wordsworth's muse seemed to swell with a richer and deeper melody when he sang:

"Again I hear
These waters rolling from their mountain springs,
With a sweet inland murmur. Once again
Do I behold these steep and lofty cliffs,
Which on a wild secluded scene impress
Thoughts of more deep seclusion, and connect
The landscape with the quiet of the sky."

But apologising for these few remarks in reference to the attractive features of our scenery, I must enter upon other considerations.

We have reason to rejoice, gentlemen, at the rapid progress which medical science is now making; and the more effective means for the relief of "all the ills that flesh is heir to" which the sister arts have supplied. The microscope reveals a new world of life, and form, and motion—the heretofore invisible region, in which the mysterious and plastic hand that shapes and builds the human fabric, conducts in silence and in secret his subtle operations, bringing this wondrous world to light; it exhibits with accuracy the elementary forms of organisation; it enables us to distinguish and characterise the peculiarities of the cells proper to each structure, to observe the movements of the minute molecules, almost to witness their growth, and to surprise, as it were, organic life in its very birth. The more intimate acquaintance with nature thus afforded, has enabled us to discriminate with great accuracy the various forms of disease, and therefore to apply our remedies with more precision, and with greater prospect of success. That fell disease cancer, for example, is becoming more accurately defined; and the structure, formation, and relations of malignant affections generally are better understood. Many affections at one time considered to be of a scirrhus nature, have been very recently subjected to the searching power of the microscope, and are now classed under the head of enchondroma, etc., and in this category are deprived of their terrors. The use of the microscope has doubtless tended also in a great degree to divest medical practice of its empiricism. A century ago, and even much more recently, very little was known of the ultimate forms of organic structures, and pathology was an untrodden land. Then the cure of disease was a purely experimental art; drugs were collected from all quarters of the world and all regions of nature, and exhibited in every variety of combination that ingenuity could devise. These were the barbarous days of medicine. How much is the practice altered now! Now the blind art is becoming more and more a clear sighted science; we walk in the daylight of truth, and though we stumble now and then, we see whither we are tending, and know the good at which we would arrive.

Dr. Morris then at considerable length sketched the progress of pathology, and dwelt on the triumphs of modern conservative surgery. He then discussed the subject of medical reform, after which he thus proceeded:—

He who desires to succeed in his profession can only attain that legitimate object, by establishing an implicit confidence respecting his skill and integrity in the breasts of those whose afflictions compel them to entrust their health and life—nay, not seldom, the carefully guarded secrets of the heart—to his honour and counsel. It is a sacred privilege—a privilege testifying with a thousand tongues to the pure and delicate honour of our brethren, that we are often made the depositories of family secrets under the most trying circumstances of life, that our judgment is often appealed to for aid, and a life of future happiness or woe often hangs upon our decision. In all such delicate occurrences it becomes us to be faithful and upright, to combine truth with gentleness, to listen with sympathy to the "still sad music of humanity", to alleviate griefs by friendly advice and succour—to act, in short, the part of the good Samaritan, who, rather than turn aside from misfortune, poured oil upon the wounds, and breathed words of comfort to the bruised heart. In this way shall we best fulfil the noble mission of our order, and act nearest to the likeness of the Divine Physician who healed the sick, the halt, and the blind, and visited the widow and the fatherless in their affliction. The conscientious and humane medical practitioner walking about doing good, appears to approach most nearly to the beautiful exemplar of our Saviour's life. He who, through his power of healing bodily infirmity, wins the gratitude and confidence of his fellow-men, makes an easy conquest over the heart disposed to lean upon his physician as a friend. In the hour of affliction the ear is open, the heart is responsive, and the truth finds a ready acceptance. It is found that the medical man is the most successful missionary in Eastern Asia. The Chinese, bigoted to their own system of paganism, politically and religiously jealous of foreign interference, and rejecting the Gospel from the lips of its appointed ministers, will listen, it is said, to the persuasions of the phy-

sician whose skill has relieved their physical suffering, and whose charity has dissipated their distrust. There is now a considerable number of our brethren engaged in the divine mission, and we bid them from our hearts God speed. How know we the important influence their teachings may have exercised over the hearts of the Chinese, and the extent to which their labours may have sown the seed of that religious movement, reported to be inspired with Christian principles, which is now rapidly spreading through that vast empire, threatening to overthrow the barriers that have hitherto separated these people from the fellowship of nations, and to bring them anew into communion with the other families of the human race?

The public owe much to the noble heroism and self-sacrificing devotedness of the medical character in many other phases of life. Cherished be the memory of the great hearted Sidney Bernard, who, when the plague ship arrived before the rocks of Madeira, with the yellow flag flying from her mast, and the dying and the dead between her decks, when the floating pest-house dared not enter the harbour, and with a tempest rising feared to put to sea, and none could be found to render aid,—

"Alone, alone, all all alone,
Alone, on a wide, wide sea;
And never a saint took pity on
Their souls in agony,"

he, the young surgeon, volunteered to the rescue, and procuring a crew of seven men from a merchant vessel lying in the harbour, went on board the dreadful ship, prepared to encounter every peril to his own life to save that of others, steered the fated vessel home to the Mother-bank, when he, too, caught the fever, and the hero of humanity fell a martyr to charity—a victim to his own generous philanthropy. Honour to Conolly, who struck the shackles from the limbs of the maniac, and by gentleness and affection rekindled the spark of reason, and recovered the suspended affections. Think of Granville Sharp, who first pleaded the cause of the kidnapped negro, and who, with Clarkson and Wilberforce, forms one of a memorable triumvirate, champions of freedom for the negro slave. But, who can enumerate—their name is legion—why enumerate the names of those men in our ranks who have signalised themselves in the cause of suffering humanity? When "the pestilence that walketh in darkness" issued from its Indian jungle, hovered over our isle, ravaged our towns, and carried death into our habitations; when friends and relations too often fled from under the roof on which the blight had fallen, in dismay and despair, and heard no comforting voice, then the members of our profession, true to their mission and foremost in duty, plunged into the noxious atmosphere unhesitatingly, and exposed themselves to the influence of the grim destroyer, glorying in the privilege of succouring the plague-stricken, raising up the fallen, the forsaken, and the apparently dying. There is an exalted degree of heroism in such acts as these, that would be given to trumpet-tongued fame if they were less common. The public expect our services, regardless of our self-sacrifices, and in few cases are they disappointed. If the soldier encounter many perils on the battle-field, surely those confronted by our own profession, the soldiers of philanthropy, in the combat with the dark and mysterious pestilence, are not less painful or deadly. We enjoy no immunity, as the world, struck with admiring wonder, are somewhat prone to fancy, which they themselves do not possess; and the medical attendant is frequently laid low in the performance of his sacred duty, by the poisonous emanations from the dying fellow creature whose life he came to save. When the cholera raged in St. Petersburg and in Sligo, the mortality among the medical men was excessive; but the fate of the fallen scared not the living practitioners from grappling with the fell destroyer. Such, then, are the perils we encounter, not only in the fearful times of great epidemics, but every day and every hour of our existence is life risked: hence our services derive a value which no conventional usages of remuneration can adequately exaggerate or repay. Let me here protest against a narrow notion, occasionally expressed, and too often governing many of the contracts for medical services, such as poor-law appointments and others, to the effect that our profession must be regarded as any other trade, and dealt with in accordance with the ordinary rules of stipendiary employment or commercial transactions. No sentiment can be more unworthy. What! does not the physician sympathise with his patient in his suffering? Is he, indeed, deaf to his groans? Does he feel no pleasure to see the cheering hues of recovery suffuse the cheek? Is there no well-wisher to his heart? Are there no electric sensibilities in his system? Invested of all those tender and sympathetic feelings, which bind us to our fellow-men, and teach us to "love our neighbour as ourselves,"

were our own"? I verily believe that a great majority of our profession feel a peculiar delight in the relief of suffering, from a generous sense of the benefit they confer; and that the thought of remuneration, if it arise, is but a secondary consideration. In truth it may be affirmed, that there is not another class of men in the walks of life that devotes so much unpaid service in the cause of humanity; and which, so far as regards temporal concerns, has made the world more deeply a debtor. But if the world may be thought occasionally to regard us from an unfavourable point of view, it may in some degree be owing to our own conduct. We should not reproach others unless we are ourselves innocent of blame. Sir Benjamin Brodie has said: "the medical profession is a noble profession, but is a low trade". Let us take care, then, that in our hands a trade it never shall become! So soon as a sordid calculation of profit and loss in relation to human suffering enters into our reflections, we lose all claim upon the gratitude of those we benefit; for we cannot expect others to regard our services more highly than we estimate them ourselves. I am happy to think that the condition, as well as the character and attainments of our profession, has much improved during the last quarter of a century. Its members generally have a higher status, a more comprehensive knowledge of medical and general science, and enjoy that distinction with the public which superior information usually confers. A more kindly and generous feeling exists also among themselves; they are more social, more confiding, and more united. The jealousies that formerly distracted and divided our ranks, and which were maintained by the absurd distinctions created by the mischievous laws that govern the profession, are rapidly subsiding, and a more cordial and generous understanding is becoming established. The heart of the profession has burst its fetters, and swells beyond the conventional restraints imposed upon it by obsolete charters and oppressive laws. The age has outrun the narrow policy of its institutions, and demands that they shall be remodelled in accordance with its high interests, its necessities, and its sense of right and truth.

To this grand result the organisation established by the Provincial Association, through the agency of my excellent and esteemed friend, Sir Charles Hastings, has mainly contributed; for through its instrumentality those who, living distant and apart from one another, engrossed in the onerous duties and anxieties of their calling, are unable to meet frequently to cultivate friendly sympathies, or to compare the results of their experience, may now, once in the year at least, or oftener, enjoy the opportunity of social intercourse, may awaken old friendships already begun to sleep, and keep alive that sacred flame which makes our life so much the happier, by so much as it enjoys more of the fostering glow of friendship with congenial minds. "*Idem velle et idem nolle, ea demum firma amicitia est.*" And they may, while renewing old associations, or recording the sad recital of those connexions that are gone for ever, add fresh ones to the register, and thus learn to experience the truth that the world never grows old to those who live in the midst of its sympathies, and will open their hearts to give them a dwelling. I can remember very well, before the institution of the Parent Association, and before, too, let me add, the establishment of railway transit became general, that the members of our profession, on settling down in a remote district, voluntarily banished themselves, so to speak, from their fellows, and were cut off from nearly all communication with the rest of the profession. Then there were few medical journals, and less taste or inclination to figure in their columns: whereas now, the name of an old friend is turning up every now and then in the pages of our weekly or monthly press, thus associating our thoughts once more with his studies and labours. This extreme individuality militated against professional sympathy, and prevented the formation of that class feeling, that pride of caste, that *esprit de corps*, which, whatever disadvantages may be thought to attend them, have the privilege of creating and sustaining a high professional spirit and zeal, and a generous and honourable competition.

There can be no doubt that the ASSOCIATION JOURNAL has had these beneficial effects; and if it should have no other advantage, surely this is one that cannot be lightly esteemed. We have received this boon from the Journal, and we owe it the duty of communicating the results of our experience and meditations, so that it may be worthy of the Association and of contemporary literature. I consider that during the past year its character and usefulness have very much improved; and I have no doubt that it will eventually become a truthful and honourable representation of medical science and practice in the provinces. There are in our ranks men of shining talents, and the largest experience. We have among us still our Jenners, our Heys, our

Dalrymples, and our Martineaus; and if such foremost men would only resolve to discard fashion, and to adopt the Journal as their organ, it would be eventually raised to the highest point of literary and scientific repute; and the Association itself would acquire dignity from the reflected lustre derived from the fame of its more brilliant and distinguished members.

The strengthening professional ties consequent on the meetings of the Provincial Association and its branches, has been of great benefit to our less fortunate brethren, through the instrumentality of the Benevolent Fund. This fund is one of the most wholesome fruits of the sympathies cultivated by our Association—a positive and real boon, whose blessings will, I hope, continue to multiply until no object worthy of our aid shall be turned empty away. Such a fund is an imperative requirement of our profession, for in no other are the means of subsistence so precarious, and health and life so uncertain. A man, full of energy, and intellectual strength, and hope, may, by an inscrutable dispensation of Providence, be disabled in an hour, or death may smite him in mid-career, and his family, deprived of his aid, may be cast penniless upon the world's wide stage. Medical men have rarely the ability to save against the vicissitudes of fortune, or the calamities of life. The necessities of a suitable establishment, even from the first hour of starting on their doubtful career; the obligation generally considered incumbent on them to marry early; the wants of an increasing family; the uncertainty of remuneration for services rendered; and the hourly encroachments upon their purse for charitable purposes, often beyond their means or their duty to meet, prevent them from making that provision for their families which is usual among other classes of society occupying a respectable position. They are not usually rich when they begin their career; and, in the majority of instances, are poor or embarrassed when they leave it. The conventionalities of their station impoverish their purses and cripple progress. Thus it happens that hundreds, alas! of our industrious and deserving brethren are working their way through the thorns and briars of the bitterest penury, or are in old age dragging a wearisome existence, until at last their families become recipients of some charitable fund. Shall not then a community, whose province it is to relieve suffering, and who must necessarily, in the course of their career, have shed priceless blessings on many a wounded spirit, receive sympathy and assistance in the day of their distress from those to whose comfort and happiness they have so abundantly contributed? Cannot the public be induced to give a little out of their superfluity to aid our struggling charities; and thus, in the most graceful and tender way, redeem a part of the obligation under which medical science and skill must at some time or other have placed every family in the land? I really believe that it is by our own fault that the public have extended so little help, and that if the cause of the widow and orphan had been pleaded with more zeal, a generous response would have been made to our advocacy. The Medical Benevolent College, now in course of formation under the auspices of that good man, Mr. Probert, a worthy companion of our Benevolent Fund, affords ample evidence of what the public are willing to do for the benefit of our humble brethren. Let the good cause go forward! There is plenty of room for extending the hand of benevolence.

Dr. Morris, after depicting quackery in its various fashionable forms, thus concluded his address:—The notoriety of a day is not true fame; and that man sells his character at a low price, who is content to barter his principles for a transitory repute. If there exist a fear that the high character which our profession has been gradually acquiring for integrity and purity of principle, and the implicit confidence now reposed in us by the public, may be shaken, if we begin to tamper with our conscience in relation to the great principles of truth and honour which should actuate and govern us as a professional body, let us avoid the possibility of the contamination. We must separate ourselves from the temptation, and show our aversion to the deceit by renouncing those who live by its profits. And now, gentlemen, I have one word to say in conclusion. I sincerely trust that this meeting will tend to cement many friendships, and to unite in a more genial and cordial manner than our opportunities have hitherto permitted, the large body of medical practitioners residing within the limits of this Branch. The relaxation from duty on this occasion will prepare you for a more vigorous application to the onerous and responsible pursuits of your vocation, on your return to your respective homes; and it is my earnest wish, as it is my belief, that our meeting this day will be found fraught with many present and future advantages, and will be associated in memory with many gratifying recollections.

Mr. BRADFORD moved the thanks of the meeting to Dr. Morris for his able address, with a request that he would allow it to be printed for circulation. The proposition was carried by acclamation.

The Secretary (Mr. MICHAEL) then proceeded to read the report of the Council, which, with the other proceedings, we must defer till next week.

[To be continued.]

EDITOR'S LETTER BOX.

THE CRYSTAL PALACE COMPANY NOT DESIROUS OF OPENING THEIR EXHIBITION ON SUNDAY.

LETTER FROM W. O. MARKHAM, M.D., TO THE EDITOR.

SIR,—I am sure, from your known candour, that you will not refuse to correct an unintentional mis-statement, made by my friend Dr. Stewart, in that letter of his, wherein he renders an account of his chivalrous exploits against steamboats, tobacco-shops, railroads, omnibuses, costermongers' carts, crystal palaces, and other pandering fosterers (on a Sunday), to the vicious propensities of our fallen human nature.

Dr. Stewart holds forth, that "tempting profits" are the inducements which have operated on the minds of a powerful trading company; that lucre, not the health of the minds and bodies of the masses, is the incentive in leading that company to hope for the opening of the Crystal Palace on a Sunday. Now, the truth is, that the Crystal Palace Company have not stirred a finger in the business; and I feel satisfied that you, who write liberally in this matter, will be glad to place on record a few of the sentiments uttered by the eloquent chairman of that company in March last, at a general meeting of the shareholders—sentiments which were countersigned, and accepted, and published as its own, by this lucre-seeking, soul-destroying company.

"Let each one," said Mr. Laing, "retain his own individual convictions . . . but let us, as a company, retain a position of neutrality; do not let us attempt to alter or evade the law of the land as we find it. . . . I think our unanimous feeling is, that if this were simply a question of profit and loss, the undertaking ought not to be opened on a Sunday. If ever it is to be opened on the Sunday, it must be from a regard to the interests of the working classes of London. That is a very large question, a question I do not mean to discuss. . . . it may be raised in Parliament; our business is to acquiesce strictly and loyally in the law of the land as we find it for the time. I may say further, that viewed simply as a question of profit and loss, my own belief is, that we have no interest whatever in getting that restriction removed. . . . I believe, as a question of profit and loss, it is just as likely that we shall gain as lose by acquiescing in the state of the law as we find it. I may state strongly and decidedly, that I do not think it is a question of profit and loss at all. . . . We, as directors, felt that this undertaking had originated very much in motives of public spirit; and rather in a desire to perpetuate and extend the civilizing processes and influences of the Great Exhibition of 1851, than as a mere commercial speculation; and, therefore, apart from any expectation of profit, it was not right that the building should be thrown open indiscriminately on the Sunday in a manner which might give well grounded offence to the religious portion of the community."

I only wish, sir, that your space would permit the insertion of the whole of Mr. Laing's calm and philanthropic views on this point; they would be found to contrast strangely with the fiery eloquence of my friend, your correspondent, and to give a much more consoling view of the depraved condition of the mercantile, "man-using-up-spirit" of this golden era, than he does. It will be a satisfaction to Dr. Stewart to hear that one of the most influential men connected with this powerful trading company, and in whose name Dr. S. will recognize a countryman, Mr J. Henderson (of the firm of Fox and Henderson), actually got up a petition *against* the opening of the Crystal Palace on a Sunday, which petition, as I happen to know, was signed by the men in his works at Birmingham.

I think I have great reason to express a doubt whether Dr. Stewart's petition does really represent the opinions of the medical men in London; my hopes that it does not, may be in part perhaps father to the doubt; but these are the reasons for my unbelief. Every man of the world knows the easy way

with which one friend will accommodate another with his signature to things of this kind; and it is notorious that extraordinary energy, the energy of enthusiasm, was exerted in canvassing for and procuring signatures to this petition. I myself was canvassed by a medical friend in my own house, and set upon by the chaplain for the same purpose at the hospital to which I am attached, where the petition was, in my opinion very improperly, laid upon the Board-room table for signature. On the other side, I have neither been asked to sign, nor have I signed, nor do I know a single person who has signed, any petition in favour of the Palace being opened on a Sunday—strongly as I am desirous of its so being.

Dr. Stewart is very hard on those who venture to differ in opinion from him. Why should "sound physiology, ordinary humanity, and, above all, Christian morality", be the property of those only who see these things with his manner of seeing them? And is he logical? He quite forgets that his conclusions are based on *opinions*, not on *facts*. You, sir, in your last number tell us that you will prove the increase of labour (it is not then yet proved), or appalling using-up of men, as Dr. S. has it, that will be requisite if the bill be passed. I am very curious to see your proofs; for my own firm opinion is, that an *actual diminution* would be the result.

Why should the spirit of Knox or Land be breathed into this medical body of ours? I admire, as much as Dr. S. can, the sentiment of our old heathen friend Terence; and it is just for this very reason, because, in my belief, humanity will be affected in all its higher attributes, by the turning of the people's minds from bodily degradations and pollutions of every sort to the pure and gentle influences of ennobling science and art, that I differ as to its interpretation from him. Let us each quietly possess and express our differing opinions, but not presume to judge of the motives of others; this is the prerogative of no earthly being.

"Let not this weak unknowing hand
Presume Thy bolts to throw,
And deal damnation round the land
On each I judge Thy foe."

I am, etc.,

W. O. MARKHAM, M.D.

Clarges Street, July 6th, 1853.

THE CRYSTAL PALACE OUGHT TO BE OPEN ON SUNDAYS.

LETTER TO THE EDITOR FROM EDGAR SHEPPARD, ESQ.

SIR,—I am anxious to say a few words on the subject of the opening of the Crystal Palace on Sundays. To my mind, which so fully accords with, and subscribes to, the philanthropic sentiments uttered by Dr. Forbes, it seems that there can scarcely anything more be added to his forcible observations. But to you, sir, who advocate, with many members of our Association (most conscientiously, I doubt not), the opposite side of the question, much more may be required ere you will feel satisfied that *ours* is the correct, and *yours* the incorrect, position.

Trusting, therefore, that you will give me credit for being actuated by the best intentions, I venture to make a few suggestions upon a subject which has already occupied, and is destined still more to occupy, so large a share of public attention.

Now, sir, it seems to me that the great mistake which the advocates of *your* view of the question are making, is that of setting apart the Sunday as an exclusive day of rest and prayer. To make it an *exclusive* day is at once to make it a drag and a heavy burden, even to many a conscientious and religious man. Superstition forbids to such a one the slightest mental culture and intellectual improvement, though he has no time to spare for such improvement upon any other day out of the seven. What is the consequence? Either he becomes a religious fanatic, calling down heavy judgments upon his happier (for his religion yields but little happiness) and equally conscientious brethren; or, feeling the thralldom of a day so unlike any other, he despises every Christian ordinance and becomes a habitual scoffer. "A few", it has been written by an able professor at one of our English Universities, "may possibly use the whole Sunday profitably for purely spiritual action; but I suspect that they are very few; and the more acute their sense of the sacredness of the hours, the greater the danger of misery from it. Especially (he continues) I can testify that for several years, when a youth and very young man, Sunday was to me the most painful; because, with all my sanctity, I could not practically reach up to my sanctity." In how many a bosom does such a response? In how many a disciplined heart does it not hear an echo?

Whether Sunday be a political or a divine institution, it is our obvious duty to turn it to the best account. And how is this to be effected? Is it by driving the poor tired artisan within the walls of some conventicle, where he may hear nothing but fearful denunciations of divine wrath against the sinful and unbelieving—where religion never wears a smile, but is clothed only in eternal frowns? Is it by enticing him within the circle of a more orthodox communion, where he might be enchanted by its beauty, and won over to the ways of godliness, but for that lack of charity which limits the divine mercy to this or that particular section of Christians? Is it by compelling him to sit in his miserable and gloomy home, with his not less miserable and gloomy family, groaning over his own and the world's unrighteousness? Ah! no, sir; you and those who espouse your views can never think this.

Rather may this profitable spending of the Sabbath be effected by each man doing what he feels most conducive to his own and his family's moral progress. It matters not whether it be listening to the Rev. Ebenezer Howler at Bethesda chapel, or meeting the Deity (where he may more surely be found) face to face in the thousand natural objects of beauty with which He has surrounded us. "If the deed be lawful, so that the moralist is satisfied, the question for the spiritualist is not, what it is, but in what spirit it is done." Shall we stop up the channel of our railroads on a Sunday, and refuse to carry out of the great and sinful Babylon some of its miserable sons of toil (toil how much increased by the demands and exactions of pleasure's daily votaries, albeit Sunday's strict observers), because the employment of a score or two of officials is involved, who might otherwise be sleeping on the platform, or boozing at a public-house? Is this real philanthropy?—nay, has it any semblance of religion? He who made us, and has meted out to some so hard a lot, will not form so harsh a judgment of the sons and daughters of six-day tribulation, because they seek to recruit their wearied and exhausted frames on the seventh day, and hold at the same time their quiet and thoughtful communion with Him, rather beneath the dome of His, than that of man's architecture. Is there nothing in the spirit of "silent adoration"? Surely God may as much, nay, far more, be worshipped thus, beneath the sky which he has spangled, than within the steamy walls of many a temple. The devout mind may find Him and worship Him in every spot: in the dewdrop, in the opening flower, in "the cattle upon a thousand hills", and in the waves of the mighty deep. And, by parity of reasoning, if the good man can find Him, the wicked man can fail to trace Him, anywhere. If we enlarge and render permanent the sphere of its usefulness, the Crystal Palace at Sydenham, like its great prototype in Hyde Park, shall contribute in no small degree to the intellectual and moral welfare of a great community. Within it is to be gathered everything of beauty and wonder in art and in nature. To these things the upper and middle classes of society may have daily access. The lower classes may have access once a week. Whose fault is it that they cannot go oftener? That of the proud and rich: that of the grasping and the selfish. It is difficult to say how the moral and religious tone of a people *must* be elevated, if it be not by constant intercourse with the works of nature and of God. The rich man can have it any day, the poor man only on what has been so aptly called the poor man's day.

Let not us, then, members of a profession which has the only true insight into the cause of disease—of a profession which yearly reveals such dreadful realities, such tales of over-taxed and exhausted frames, dropping prematurely into unhallowed graves—let not us, I say, choke up the opening avenues to so much good. Let intellectual and moral growth attend the progress of our common Christianity. And "he is the best Christian," be it remembered, "who most advances the cause of mankind."

Is that cause to be promoted, or is it not, by the opening of the Crystal Palace on Sundays? I maintain that it is, even against the opinion—"Alas! that it should be so" (as Dr. Forbes says)—of 640 medical men! The extract quoted by this learned physician and noble philanthropist, from his recent work on Ireland, cannot be too earnestly perused by the 640 gentlemen above alluded to. May they never know the privations and sufferings necessarily incidental to the lot of the swarming populations of our great towns; may they breathe more of the breath of heaven than these poor wretches breathe in their weekly round of irksome toil; may they see as much of nature and nature's God *every day*, as not specially to require both for one day.

I am, etc.

EDGAR SHEPPARD.

Enfield, July 9, 1853.

THE SABBATH.

LETTER TO THE EDITOR.

SIR,—Yours is a difficult course to pursue, considering how many people you have to please; but as you have thrown down the gauntlet in your article entitled "SUNDAY—AT HOME OR ABROAD?" you must allow me a word on the same side of the question which my friend Dr. Forbes has so quietly and yet so well advocated. It is extremely undesirable that our JOURNAL should become theological as well as medical.

I do not for a moment impugn the motives of Dr. Stewart and his coadjutors; and I claim from them the same charitable judgment. I yield to no one in my desire that the first day of the week should be devoted to rest from labour—to the worship of God—and to the attendance on those means of improving our moral nature which are within our reach, whether at home or abroad, and to the cultivation of all the social virtues: that it should be the day when all the cares of the present state of existence should be banished from our minds.

We live in an age of combinations. The human hive could not for a week hold together if we all had to brew our own beer, bake our own bread, make our own clothes, etc. It is the same principle which is a necessary result on Sundays of the congregation of large numbers of human beings in cities and towns. I stepped into a baker's shop last Sunday, in a bye street, and asked him how many dinners he had cooked? He answered, seventy. That is to say, seventy families were saved cooking on Sunday, and were able to go to church. From Dr. Stewart's special mention of "the bakehouse", one might suppose he objected to this arrangement. In some primitive conditions, such as that of the Israelites, it was possible—nay, it was necessary, in obedience to God's commandment—to abstain from all labour on the Sabbath day. Yet what a rebuke was administered to the Pharisaic observers of the outward show by our blessed Lord himself!

Now what is a day of rest to Dr. Stewart, to you, and to me? Dr. Stewart sits in his library after service, and reads the last controversial tract. You, sir, I have no doubt, lock up your study, and do not open a letter till Monday. My rest is a cigar and a good book, in the greenhouse. Now, take a tradesman, and ask him what his rest would be. Assuredly the grocer would like to get away from the smell peculiar to his trade; the tailor would find little rest in sitting—Heaven bless him, he has been sitting the whole week!—and so it is with all. True rest to them is utter separation from and forgetting of their weekly occupation. They ought to know that their first duty is the worship of God their Creator, their preserver, their Saviour; and this, the first, should sanctify the whole duties of the day, should throw a solemnity over everything that is undertaken or that is spoken; should hallow us, our tongues, our hands, our very thoughts.

But what is worshipping God? It has, by a strange perversion, come to signify the passive act of listening to a sermon. Now, to my idea, worship is an act of itself, and far too seldom entered into and sought as a means of gaining heaven's blessing on our daily work. But, having worshipped God, not as a form, but as a reality, are we to insist upon people all staying at home for the rest of the day? Is the whole machine to stand still for the sake of the few dozens required to set it in motion? Most decidedly not. But it is wearying to argue with those who insisted that relays of horses and postboys should be kept ready on the old coaching roads, in case of sickness, etc., on Sundays, involving the labour of hundreds, that two stokers might be saved from working. The police must be on duty; the scavengers must sweep away our refuse; and it is no less an act of necessity and mercy to give the poor the means of getting away from the scenes of their weekly toil. I thank God, I live in the country, and I rejoice to see, on Sundays, the roads in each direction pouring forth their stream of well dressed artisans with their wives and their children. I have a cold dinner, and sit at home, because that is my true rest, my Sabbath. They go abroad, because their Sabbath consists in motion. What a fearful result has been found in Glasgow and Edinburgh of the severe discipline of the Sabbath as there outwardly so well kept! It is this—that a large proportion of the population are on Sunday steeped in whiskey.

It is an evil thing that the misdirected exertions of such good men as Dr. Stewart and others drive men to despise the Sunday, and to seek the advocacy of the infidel and the unbelieving philosopher. If the six hundred and forty medical practitioners would each put down their £5 to build a church at Sydenham; to have the most gorgeous ceremonial; the most captivating music; the most eloquent preachers if you will; anything to

allure people to the house of God; that even the scoffer may stay to pray. Oh, if the clergy were not asleep, would they not be up and doing—would they not have early services, real morning prayers and early communions for those who could then attend them, and seek a blessing on their holy day?

One more point—I suppose one is to give just as much weight to the six hundred and forty signatures to this petition as was to be given to that of the teetotallers. It was difficult to refuse when asked to sign it; but it has made me very sceptical indeed of the sincerity, particular of “the most eminent” of our profession.

I am, etc.,

ISAIAH lviii, 5.

THE SABBATH.

LETTER FROM JOHN GRABHAM, M.D., F.R.C.S., TO THE EDITOR.

SIR,—I am unwilling to obtrude my feeble pen upon your pages; but my attention has been arrested by your last week's leading article, and a sense of duty prompts me, as an old member of the Association, to express my deep regret that, through ignorance of what was in progress, I did not attach my name to the petition against opening the Crystal Palace for gain on Sundays—even though I place myself with those who are only “moderately versed in the knowledge of human nature—the charlatans” of Dr. Forbes. The well earned high position of this gentleman gives double force to opinions promulgated by his letter to you; and I believe them to involve the penalty of “doing evil that good may come!”

Belonging to the Church of England, I am commanded, every Sunday morning, to “keep holy the Sabbath day”; and I utter the prescribed response—a prayer for grace to do so. Immediately afterwards, Dr. Forbes would have me travel “by land or by water, by omnibus, boat or rail”, pleading the advantages of relaxation, while I “forge additional chains” for the poor creatures by whom I am conveyed! “Strange and most illogical indeed!” The doctor will pardon this echo of his own words. Alas! I fear such “philosophical consideration” is akin to that which was long ago described as “philosophy, falsely so called”. He mentions “religious exercises and study” as “retarding progress by over long persistence”. “The brain,” he says, “is apt to be exhausted, and the thoughts to become weakened and confused, in religious pursuits.” It may be so under the discipline of Ignatius Loyola; but, happily, the system to which I adhere is “perfect freedom”.

I have been for forty years a hard-working member of the profession; and, as I am anxious to show that my conclusions are the result of experience, I may be permitted to “magnify my office” (which Dr. Forbes's station leaves at humble distance), viz., that of appointed medical attendant to large numbers of the poor; of whom I unhesitatingly assert, as a general rule, that their habits are respectable, or otherwise, in proportion to their correct observance of the duties of the Sabbath, and their abhorrence of *Sunday pleasure jaunting*, which, in my observation, has been almost invariably the precursor of dissipation, poverty, and domestic misery.

Dr. Forbes appeals to “everybody who has had anything to do with the instruction of others, or who has ever attempted the acquisition of knowledge in his own person.” I lament, indeed, my own short comings; but the importance of illustrating a subject so vital bids me spurn the imputation of vanity, and claim for my family the honour of having instructed hundreds of poor persons of both sexes, adults as well as children, by unwearied personal efforts at *Sunday schools*, which an extended adoption of Dr. Forbes's views would annihilate.

Often am I cheered by letters to members of my circle, from persons now respectable and scattered widely about the world, expressive of undying gratitude to those who snatched them, when Sunday wanderers, from “the highways and hedges”, and taught them—not merely to read and write, but—to value, as Christians, the privilege of Sabbath services; while, provident and well conducted, they found legitimate opportunities for healthful recreation.

With profound respect for the intellectual powers, the moral virtues, and the good intentions of Dr. Forbes, and passing over his “hard words”, I venture to submit, that even “the wise and prudent” are not always safe expositors of Divine truth. I am thankful for his admission, “that there is a growing disposition among the clergy and the upper classes generally in England”, to accord with the six hundred and forty of our brethren who discharged a sacred duty. The “astounding

announcement” might engender misgivings. Long may the doctor live in health and happiness; and, when age advances, may he cheerfully confess that—

“The soul's dark cottage, battered and decayed,
Lets in new light through chinks that time has made.”

I am, etc.,

JOHN GRABHAM, M.D., F.R.C.S.

4, Lonsdale Square, Islington, July 4th, 1863.

THE MEDICAL PROFESSION AND THE CRYSTAL PALACE.

LETTER FROM H. SANDWITH, M.D., TO THE EDITOR.

SIR,—You will have a provincial response to your editorial remarks, on the proposal to open the Crystal Palace on Sundays, quite as cordial as that of the six hundred and forty medical men of London. You take a true ground in shielding a large minority of working men from increased toil on the Lord's day, in the event of its more extensive desecration; and not less so when you designate the remedies proposed by certain politicians for the diseased condition of an overworked population, as “charlatanic treatment of the body politic”. In the wish you express, “to maintain Sunday as a domestic day”, for purposes of family converse and religious instruction, you also faithfully echo the wants and wishes of society. All these are sound and wholesome views of the question at issue, based as they are on a regard to the moral, no less than the physical, wants of human nature. Full justice cannot indeed be done to the former in pages devoted to physiological science.

Let the question, however, be fairly stated. One might suppose, from the way in which the promoters of the opening of the Crystal Palace on Sundays argue, that a legislative refusal to grant this indulgence would imply the extinction of all existing facilities for recreation on that day; whereas, the real question is, whether things shall remain as they are, or whether a floodgate shall be opened to inundate the country with such scenes of Sabbath profanation as those which deluge the continental nations.

Neither is the question fairly stated, when it is assumed that the *opponents* of the opening of the Crystal Palace on Sundays are satisfied with the existing condition of the operative classes. They cheerfully admit, that a greater amount of out-door recreation is necessary both for their health and for the improved character of their religious exercises.

How then are the admitted evils of the present system to be met, so as to secure the required physical and moral good?

Yourself and others have suggested a solution of the difficulty, by proposing for the operatives “a weekly holiday”. There are, moreover, indications of a heaving in the bosom of society for the adjustment of this claim of the operatives on their employers. Witness the victory achieved in the case of factory labour. Witness the early closing of shops. Witness also the anticipation of the very suggestion before us by the successful movement in Manchester, and partially in Glasgow, in favour of a weekly half-holiday. The petitions against the opening of the Crystal Palace on Sundays were signed in sufficient numbers by the operatives themselves, to show that Sabbath dissipation is not the source to which they look for relief; but rather to an occasional closing of the Temple of Mammon. While the physical wants of human nature justly demand some relaxation from toil on week-days, its moral ones can ill afford more time for recreation on Sundays. The religion cherished by the existing order of things in England and Scotland may be stigmatized as “technical”; but who that has compared Paris with London, can doubt for a moment which of them contains more of the sham, and which more of the reality of devotion? We may admit, that “over-done” religious exercises and study are “ill done”. But to warrant the implied censure, it should be shewn that our religious services are of inordinate length, leaving too brief intervals of repose, or that the change of occupation on Sundays yields no advantage, and is fraught with no special solace. It is marvellous how easy one should, from mere physiological and hygienic considerations, conclude that a sound philanthropy suggests what must be considered an invasion of the sanctity of the Lord's day, to secure justice to the labouring man. The annals of these speak another language. They tell of Sabbath profanation, with all its boasted physiological advantages, as being one of the most prolific sources of vice. The *most* of these relaxation every year from bodily toil, gained from the Crystal Palace, doubtless aimed at securing

than physiological advantages; for here, as in all other beneficent arrangements of the Deity, a simplicity of means is crowned with a complexity of results. So long as the claims of physiology and an enlightened hygiene can be fairly met on the lower level of political economy, there is nothing to warrant us in invading higher and holier ground, and in frittering away the sanctity of the Christian Sabbath.

I am, etc.,

HUMPHRY SANDWICH.

1, Albion Street, Hull, July 4th, 1853.

THE SABBATH.

LETTER FROM CHARLES COWAN, M.D., TO THE EDITOR.

SIR,—I am much pleased with the general tone and tendency of your two leading articles upon the question of Sabbath observance.

That a large majority of the medical profession do think and feel with you, it is pleasurable to believe; and that your views are justified by the records of the past, and sustained by an authority, which, when once submitted to, becomes supreme, cannot be successfully disputed.

Independently of the axiom, that no secondary good can ever justify the use of wrong instrumentality, and that the classes of our population for whose advantage the proposed innovation in our habits is ostensibly intended, are precisely those who would be burdened and not benefited by the change—there is, as you rightly maintain, the long and uniform evidence of experience, to warn us that the moral elevation and physical well-being of a people have in no degree corresponded to the prevalence of Sabbath amusements, but have ever been closely associated with the national recognition of the law which God has imposed, and of their observance of the precepts which our common Christianity enjoins.

It is madness to imagine that the best interests of any population can be promoted, by indulgences at variance with the dicta of revealed truth; and whosoever may attempt to solve the vast problem of man's social improvement by means inconsistent with God's requirements, will only demonstrate anew their inefficiency and folly, and aggravate the disease they are intended to remove.

The simple truth is, that the neglect of Bible principles is the true solution of our unsuccessful schemes and of our endless controversies, and no age is more illustrative of the fact than the one in which we each now play his little part. Empiricism, in law, physics, science, and divinity, is everywhere rampant. The Tower of Babel is again being raised with a renewed and frantic zeal, and we are vainly anticipating the advent of a coming blessedness as the reward of our own contrivings.

I am, however, quite aware, Mr. Editor, that our JOURNAL should not be the arena of theological discussion; but at the same time I trust, that in the advocacy of every great question, where principles higher than human wisdom demand their proper application, you will not hesitate to give them their due prominence in the discussion, feeling confident that by so doing you will command the approval and sympathy of the great body of your readers.

I am, etc.,

C. COWAN.

Reading, July 5th, 1853.

THE SABBATH.

LETTER FROM JAMES MILLER, Esq., F.R.S.E., PROFESSOR OF SURGERY IN THE UNIVERSITY OF EDINBURGH.

SIR,—I am much gratified to find that you editorially take up the defence of the Sabbath; and I do most earnestly hope that the profession will support you, thoroughly, in the course you are pursuing.

Dr. Forbes has done great and good service in his day to the profession; and there is no man for whom I entertain a higher respect. But this does not prevent me from saying that there is nothing from which I more entirely dissent, nothing which I more deeply regret, than the sentiments he has expressed in regard to Sabbath observance, in our ASSOCIATION JOURNAL for July 1st.

In my own mind, the whole matter in dispute resolves itself into an appeal to God's law, as revealed in His word: a law which will ever be found in perfect harmony with enlightened human experience. The wisest and most observant of all men, in all times, have rested most satisfied that "the conclusion of the whole matter is, *Fear God, and keep His Commandments; for this is the whole [duty] of man.*"

The higher and more accurate the progress of all philosophy, the more surely will it tally with the truths of the Bible. Geology and astronomy, for example, at certain points of their extension, may have seemed to come into collision with these; but the very next step of real progress has exhibited them more clearly than ever in the attitude of stern and faithful witnesses.

And so it is, and will be, with the philosophy of the human frame. It is a crude and imperfect physiology, which opposes itself to the Fourth, or indeed to any of the Ten Commandments. The more perfect that science becomes, the more plainly will it declare that God's way of spending the Sabbath is the best for the body, as well as for the spirit of man. And therefore, while I cordially approve of what you have done, I do desiderate that you mount up from the platform of mere philosophy, and argue the question on Bible ground. "To the Law and to the Testimony! If they speak not according to this Word, it is because there is no light in them."

I am, etc.,

JAMES MILLER.

51, Queen Street, Edinburgh, 5th July.

THE SABBATH.

LETTER TO THE EDITOR.

SIR,—I beg to give you my best thanks for the manly, straightforward way in which you, as Editor, have expressed your opinions on the effect of converting the English into the Parisian Sunday. That the great majority of our members will agree with you, I have no doubt at all. The question is a poor man's question, for he will be the sufferer; and the working men of London are beginning to view it in its true light—that they will be the losers, and their day of rest will be curtailed for the amusement of those who are richer than themselves.

I lately read a pamphlet, by a shoemaker, named Delvin, in favour of opening the Sydenham Palace on Sundays. It was written with spirit, power, and eloquence; but all the arguments he brought forward were, according to my mind, upset by his own admission in the conclusion.

"Even now," (writes this powerful shoemaker) "I am no willing desecrator of the Sabbath. Lightless and unlettered as my teaching and bringing-up have been, I have in some way grown to pay to it a more respectful deference, and feel for it much sincere admiration. To me, and such as me, it has always been the best of friends; its whole history tells me so; for had it not been for the institution of such a day, *mammon*, indeed, long ere this, would have reigned all-dominant; powerless toil be whipped to its task of the day on every day—no rest, no nothing but work—ignorance, filth, nudity, disregarded complaining, unsavoury and meagre food, and a rapid death! I cherish, then, almost to adoration—nay, even to actual adoration—this so-far bulwark against unmitigated industrial slavery and uncommemorated wretchedness."

These are burning words seething up from the hot and vivid experience of an actual life of toiling poverty; and were the writer as broad in his views as he is energetic, he would have seen that he was undermining the very building whose structure he was admiring and trying to improve; or, according to the more homely and apt illustration, he was killing his goose for an immediate supply of golden eggs. He adores the present day of rest—he looks at it as the only bulwark between him and the complete despotism of *mammon*; and yet he would open the way to a complete change of its character. Make the Sunday a day of amusement and pleasure, instead of a day of rest, as it is now, and the poor of the nation will suffer just as the servants of a family do when their employers enjoy themselves. The family, for instance, enjoys its Sundays, making the day one of festivity; and the servants are kept in the kitchen, and worked harder than on any day of the week. Another family habitually acts in a way to decrease their work, having nothing cooked or done on that day which can be cooked or done on the previous or succeeding day; and their servants enjoy a quiet day of rest, and are thankful for it. So is it with a nation. The poor will suffer. If it is not a day of amusement to them, it is a day of rest; and now that they have got it, may they (with God's help) keep it, and employ it in his service.

I am, etc. A MEMBER OF THE COUNCIL.

July 5th, 1853.

ON THE PROPOSAL TO OPEN THE CRYSTAL PALACE ON SUNDAYS.

LETTER TO THE EDITOR FROM HENRY DAYMAN, ESQ.

SIR,—I cannot but admire the manly and independent spirit you have shown in your articles on the Sunday pleasure controversy: and this feeling has been shared by many much esteemed associates with whom I have lately conversed.

The subject appears capable of being viewed under two aspects, namely, How does the proposal to throw open the Crystal Palace on Sundays affect us as citizens? and how as medical men?

To answer the first question, it would not be difficult to produce evidence, drawn from authentic sources, to show that, from the earliest ages of Christianity, the Lord's day has been observed as one of sacred rest, of joy and gladness; and that the first Christians carefully avoided keeping the Sabbath day after the manner of the Jews, which consisted then, as it does now, in following secular amusements. Religious exercises, and the moral training of the mind, were the especial duties of Christians on Sunday. Thus St. Ignatius says, in his *Epistle to the Mag-nesian*, "Let us no longer sabbatise, but keep the Lord's day, on which our Life arose"; and Lord Chancellor King, in his excellent work on the "Primitive Church", tells us that "the way wherein the first Christians sanctified the Sunday was the employing of themselves in acts of divine worship and adoration". Moreover, there is something revolting to Englishmen in the idea of throwing open a place of public amusement on a day which from time immemorial has been kept holy.

I am well aware, sir, that many excellent men would tell us this is a question with which the legislature has nothing to do, and that "the law of liberty" forbids the civil magistrate to interfere with the Christian's conscience; in fact, that people should be left to follow their own ways, in order to test the sincerity of their faith. To this I answer, that, if the people themselves ask for protection even against themselves, it is the business of the rulers to listen to the appeal. Now, it is well known that the mind of the public is against opening the Crystal Palace on Sundays; and, therefore, if the sense of the community has been taken in the matter, the duty of a wise government is made clear. Let those gentlemen who affect to ignore what is called a *national* religion listen to the words of an old divine, who certainly was not prejudiced in favour of church, or any other principles of an established form. Speaking of Sunday, he says, "On this day, throughout all ages, hath the edification of the churches been carried on, and that public revenue of glory been rendered unto God which is his due. Not only have the wisest and holiest men, who have complained of the sins of their several times and ages wherein they lived, which procured the pouring out of the judgments of God upon them, constantly reckoned the neglect and profanation of the Lord's day among these sins; but such instances have been given of particular severities against them who have openly profaned this day, and that upon unquestionable testimonies, as may well affect the minds and consciences of those who profess a reverence of God in the holy dispensations of his providence."

In discussing the second part of our subject—namely, how the question at issue affects us as doctors—I have no intention of introducing arguments either for or against the proposed scheme on physiological grounds. It may be that the laws of mind are derivative laws, consequent on those of animal life; but this does not appear to me a proper place to engage in an analysis of psychological principles, founded on the imperfect data which physiology at present can furnish. Such an inquiry belongs to the subtle logic of the moral sciences. It is enough to know that six hundred and forty thoughtful practitioners in medicine have given their verdict on this important question; and this fact alone is sufficient to justify the editor of a journal which is supposed to reflect the mind of two thousand gentlemen in drawing attention to the subject, and to command the serious consideration of every right thinking member of the profession.

I am, etc.,

HENRY DAYMAN.

Milbrook, Southampton, July 12th, 1853.

[Letters in defence of Sabbath observance from Dr. ALLISON and Dr. COWDELL have been squeezed out by the advertisements encroaching on our space. They are in type, and shall appear next week. EDITOR.]

LIEBER. 12mo. cloth, 6s. 6d.

Wythes.—Microscopist; or, a Complete Manual on the Use of the Microscope, for Physicians, Naturalists, and all lovers of Natural Science. With Illustrations. By JOHN WYTHES, M.D. 12mo, 6s.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XXIX.

LONDON: FRIDAY EVENING, JULY 22, 1853.

NEW SERIES.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY. In reply to several letters which we have received from Edinburgh, requesting us to add the Edinburgh Medico-Chirurgical to the societies of which we give regular reports, we beg to say that we shall be very glad to arrange with a competent and trustworthy reporter for the meetings of next session. Persons who will engage to furnish faithful and early reports, we are prepared to treat with. In mean time, we have obtained reports of the recent meetings of the session which has just concluded.

PROPOSED SOCIETY FOR THE SUPPRESSION OF FRAUDULENT AND OBSCENE ADVERTISEMENTS.

On the 17th of June, we presented to our readers some observations upon "Four Strongholds of Quackery in the Fourth Estate", in which we particularly directed attention to—

- I. NEWSPAPERS, especially those published in the Provinces and in the Colonies;
- II. RELIGIOUS (?) PERIODICALS;
- III. PSEUDO-MEDICAL PAPERS; and
- IV. MEDICAL JOURNALS.

Since the period referred to, we have been in correspondence, upon the subject of the suppression of fraudulent and obscene advertisements, with many influential persons; and the conclusion generally arrived at has been, that this object might be accomplished, to a great extent, by a judiciously managed society; but that, without the organization of such a body, little fruit could be expected from the isolated efforts of respectable editors and others. We expect very soon to be able to announce the actual establishment of this society—a society with which we shall always be rejoiced to co-operate, in endeavouring to redeem the better part of the periodical press from its present degraded position of hiring servitude to medical swindlers and obscene advertisers. The literature of Holywell Street, and the pseudo-medical papers, may be found to require special treatment.

If the attack on quackery in the fourth estate be wisely directed and well sustained, it cannot fail to be crowned with success. There are a few, we know, ready to maintain, that so essential is the money of the quacks to the very existence of most of the provincial newspapers, that such an attempt as that proposed can only be regarded as a well meant but hopeless crusade. A pretty extensive inquiry into the state of public feeling leads us to adopt a more cheering view of the case. We feel assured that there is an enormous power, slumbering at present, but quite ready, upon a proper signal being given, to march forward in united phalanx, and drive forth the quacks from their "strongholds in the fourth estate", which at present seem almost impregnable. The reformation required is fortunately keenly desired not only by the medical profession, but by large numbers of the nobility, clergy, and gentry.

The preliminary organisation must be extensive and careful; and the movement, when once commenced, must be ever onward, with unflinching hand and unfaltering step: but, if these conditions be complied with, victory is certain.

As some encouragement to deal faithfully and firmly with offenders in the fourth estate, let us recall attention to our former remarks upon the appearance of quack advertisements in periodicals aspiring to be considered the champions of religion. We particularly complained of the strange inconsistency of the *Edinburgh Christian Magazine*, which, in its number for April last, denounced quackery as a practical "denial of the wisdom of God's arrangements in the world", and yet sold a place upon its wrapper to the *soi-disant* Professor Holloway, for his "extraordinary cures". The publishers, to their honour be it proclaimed, have for the future resolved to keep their advertising columns free from Holloway's swindling notices; and we have no doubt that many other proprietors of papers which seek to be called religious and Christian, could be induced, by means of suitable representations, to make their conduct harmonize with their professions.

Dr. DOUGLAS MACLAGAN, of Edinburgh, on perusing our article of June 17th, to which we have already referred, forwarded it, with an expostulatory letter, to Messrs. PATON and RITCHIE, publishers of the *Christian Magazine*. The high character and respectability of these gentlemen may be inferred from their reply, which we subjoin:

To Dr. DOUGLAS MACLAGAN, }
Heriot Row, Edinburgh. }

Edinburgh, June 20th, 1853.

DEAR SIR,—We have to thank you for drawing our attention to the article in the ASSOCIATION MEDICAL JOURNAL, anent quackery: but we had previously determined to withdraw the advertisement from the columns of our Magazine. We are

Very truly yours,
PATON AND RITCHIE.

Most of the cheap serials are contaminated with fraudulent advertisements of various descriptions. There are, however, some honourable exceptions. The *Family Economist*, published by Groombridge and Sons, Paternoster Row, disdains all quack advertisements, and in this sets an honourable example to other publications which pretend to offer unexceptionable domestic reading.* The *Scottish Guardian*, a Glasgow newspaper, excludes quack advertisements; and we believe that there exists a small and honourable self-denying minority who act in the same way. Generally speaking, the Scottish newspapers are much less offensive than the English provincial papers; and those printed in Edinburgh—though some of them are open to severe censure—are, as a group, decidedly the most respectable regarding which we have as yet had complete returns.

* We recommend this modest publication to the notice of our readers. Volume Fifth, price One Shilling, containing 236 closely printed pages, is now before us. The *Family Economist* is written chiefly, we believe, for intelligent artisans.

The journals pretending to strict religious principles and aspiring to be the organs of particular parties, when they do transgress, are certainly the most demoralizing of this class of offenders. They gain access to families from which papers avowedly licentious are excluded; and thus religion herself is made the pimp of vice.

The *North Wales Chronicle*, of July 15th, has been sent to us, we presume, in consequence of some observations which it makes upon our echo of the censure lately passed by the North Wales Branch of the Association upon its unfairness in its treatment of Mr. Duncan. The paper, however, is more useful to us as affording a ready example of the class to which it belongs, and against which it is our special duty, as good citizens and medical journalists, to defend society and our profession. The *North Wales Chronicle* devotes a great portion of its space to quack advertisements and ecclesiastical affairs. What Dr. Forbes has so well named "technical religion" is the obtrusive religion of this newspaper. For example, the proper way of repeating the Lord's Prayer is very learnedly handled according to the doctrines of various authorities, including "Bishop Mant, one of the greatest of modern ritualists". One correspondent writes as follows:—

"And as to the alleged custom of the Universities, I question much, from all that I can learn, whether it be true as regards some of the college chapels. And even if it were so, this point is not to be decided by a majority, for in that case it might turn out that, in the Principality at least, we should not have the Lord's Prayer repeated by the people at all. Besides, at the Universities, they always kneel and pray into their caps at the 'bidding' to prayer before the sermon, whereas when the prayer itself (i.e. the Lord's Prayer) is said by the preacher, they do not at all join in it, though *bidden* or exhorted so to do; and such I apprehend is the case in most of our cathedral churches."

As another specimen of the religion of this newspaper, we quote a few lines from the editor's denunciation of the Roman Catholic religion.

"It" (the Roman Catholic religion) is the fiendish system under whose direct auspices such atrocities were perpetrated, that is now attempted to be reimposed upon the people of this Bible-reading and liberty loving country. It is to bring back this organized system of blasphemy and foul superstition, red with the blood of martyrs, that the superhuman efforts of the Propaganda are directed. They instinctively feel that so long as the Protestant institutions of these realms flourish, there is no hope for the regeneration of the world. While the fleets of Great Britain carry her missionaries to the remote ends of the earth to proclaim the glad tidings of salvation through the merits of a crucified Redeemer alone, the devotees of an effete creed dread the mask being torn, that conceals the hideous deformity of Popery."

In juxtaposition with communications on the technical performance of the Lord's Prayer, and the above passage about Popery, we have many columns of quack advertisements. Among them in bold relief at the top of a page, with the prefix

HEALTH FOR ALL WHO NEED IT:

we find a beastly proclamation from a veneralist—a document which is an outrage not on Christianity alone but on the common decencies of social life. That no one may impute to us unnecessarily severe language, we quote a part of this disgusting manifesto; which, we may remark, is issued by "a chemist" residing in the market place of Bangor, and who is the agent of the vile veneralist.

"A Medical Book on the Physiology of Marriage, Infelicitous and Unproductive Unions, and other Secret Infirmities and Disorders of Youth and Maturity, usually acquired at an early period of life, which enervate the physical and mental powers, diminish and enfeeble the natural feelings, and exhaust the vital energies of Manhood; with practical observations on the Treatment of Nervous Debility and Indigestion, whether arising from these causes, close study, or the influence of tropical climates: Local and Constitutional Weakness, Syphilis, Stricture, and all Diseases and Derangements resulting from Indiscretion. With Coloured Engravings, illustrating the Anatomy, Physiology, and Diseases of the Reproductive Organs, explaining their structures, uses, and functions, and the various injuries that are produced in them by solitary habits, excess, and infection."

"Country patients are requested to be as minute as possible in describing their cases, age, mode of living and general occupation. The communications must be accompanied with One Pound for Advice and Medicine, without which no notice can be taken of their application, and in all cases the most inviolable secrecy may be relied on. Medicine can be forwarded to any part of the world, however distant, securely packed and carefully protected from observation."

It is passing strange that a newspaper containing such a hotch potch of Christian archaeology, fiery protestantism, and unveiled obscenity, should be tolerated in this Christian kingdom; and yet we grieve to say that it belongs to a numerous class of publications which are to be found in the drawing-rooms of our gentry, and even in the studies of some of our less thoughtful clergy. Is it not written—

"Woe unto you, Scribes and Pharisees, hypocrites! For ye pay tithe of mint, and anise, and cummin, and have omitted the weightier matters of the law, judgment, mercy, and faith: these ought ye to have done, and not to leave the other undone."

"Ye blind guides, which strain at a gnat, and swallow a camel."

The editor of the *North Wales Chronicle* appeals to his readers as a Bible-reading people: and it is therefore quite in place for us to tell him that although the Bible does not direct us to say the Lord's Prayer "into a cap", or according to any other prescribed ritual, it distinctly tells us—our Saviour himself says it—that we are to use this form of words, "when we pray". The prayerful heart is the only thing exacted. The man who, with sincerity of soul, prays, "Thy kingdom come, Thy will be done on earth as it is in heaven", will assuredly agree with us in thinking that it is more important to exclude obscene reading from our families than to settle the cap controversy, or to abuse the Papists. It is worse than folly to waste our strength and our days in contending so eagerly about the archaeology and fashion of the casket of Christianity as to lose sight of the priceless gem itself; allowing it to be trodden upon by the feet of the scoffer as a worthless and vile bauble, while we proceed with our puerile wranglings.

Here, for the present, we must leave this subject; and in doing so, we have peculiar pleasure in calling the attention of our readers to the letter of *Πιστοβυρεπος*, printed in a subsequent page.

As St. Paul was accompanied in his evangelistic journeying by "Luke, the beloved physician", so let us at all times rejoice to go hand and hand with the faithful heralds of the cross: but in doing so, let us beware lest we give any occasion to the adversary to say, that we are using religion as the cloak of charlatanism.

We have been led into the above train of thought by the

conviction that fraudulent and obscene advertisements can never be suppressed except by a firm alliance between the two sacred professions. The proposed society must work as much through the piety of the clergy as through the orthodoxy of the medical profession.

DISCUSSION IN THE HOUSE OF COMMONS ON THE SALARIES AND SERVICES OF POOR LAW MEDICAL OFFICERS.

A FEW nights since (July 12th), Mr. MILES rose in his place in the House of Commons, to make a motion on Poor Law Medical Relief.

In strict accordance with an old custom, the members present were so few in number when the medical question came into the field of argument, that the House had to be counted, in order to satisfy a listless member that the necessary "forty" were really present. The "forty" being present, Mr. Miles opened the debate, and was followed in turn by Mr. Baines, Sir John Trollope, and Mr. Wodehouse.

It is due to these gentlemen to say, that they all considered that the salaries of medical officers were "low"; and Mr. Miles and Mr. Baines have supplied us with so many interesting calculations on poor law medical matters in general, that we are able to present to our readers, in a very few lines, a more full and correct statement of the value of poor law medical appointments, than has been offered perhaps at any previous time.

It appears, that the number of parochial medical officers in England is 3,233, and that the number of poor patients treated by these officers annually is 835,000, or about 260 patients by each officer. The sum paid for medical relief in the year 1852 was £212,050, to which must be added £25,894 for vaccinations, and £30,727 for "extra fees for surgeons"; the whole affording the sum of £268,671, which, being divided amongst the 3,233 officers, gives to each the average sum of £83 : 2 : 0½.

This is the rate of payment of our parochial officers. Let us now look at the services rendered by them for that payment. We have before said, that each officer has under his care 260 patients annually, according to Mr. Baines's figures. As these are all cases that have been returned in the medical relief book, it is fair to infer that they are all serious cases, and cases requiring long and careful attendance. From a large amount of personal knowledge on this subject, we would not fear to state that, in cases thus returned, the average number of visits paid is from ten to fifteen; but, as we wish to speak under the mark rather than above it, we will content ourselves by saying that the figure 7 shall represent the average number of visits paid to each patient, and the average number of times that medicines are supplied.

With reference to vaccination. The amount received by all the officers is £25,894, implying, at 1s. 6d. per case, which is the highest sum paid, 388,410 vaccinations, or rather more than 120 vaccinations by each officer, annually.

In extra surgical fees £30,727 are paid. The cases for which these fees are received are generally cases of fractures and dislocations, with an occasional amputation or an operation for hernia. The fee in these cases varies from £1 to £5: we will take £3 as the standard. This will give a total number of 10,262 special surgical cases to the medical

officers collectively, and, we will say, three cases to each individually. It must be borne in mind that these are all very serious cases, cases each of which is on hand at least six weeks, and has to be visited three or four times weekly, often many times more, during the whole of that period; so that, if we say that seventy-two extra surgical visits are paid on an average by each parochial surgeon in the course of the year, we shall speak under the truth.

To sum up: Were the sums paid to poor law medical officers equally divided, and were their services also equally divided, an account sent in at the end of the year by one of them, might be represented as follows:

To professional attendance on 260 patients, including one thousand eight hundred and twenty visits, and necessary medicines on each visit	£65 11 9
Vaccinating 120 persons	8 0 2
Attendance on four serious surgical cases including seventy-two visits, surgical appliances and medicines	9 10 1
Total	£ 83 2 0

This is, indeed, a most strange looking account. If the reader will consider each vaccination as equivalent to a visit, (it is something more, for the vaccinator must look after the vaccinated and report the success of the case) 2,012 visits, at most of which medicines are supplied, will be found to have been made. Divide £83 2s. into 2,012 parts, and 9¾d. comes with impertinent smallness before the eye—9¾d. per visit and medicines, and a ride or a walk of six miles—9¾d. per surgical operation, and a burthen of responsibility that would make Atlas bow-legged in a fortnight! Rather gentlemanly pay this, to a member of a gentlemanly profession, from a gentlemanly public, is it not?

"It is a long lane that has no turn in it", says the old proverb. The lane of misery in which we travel now *has* no turn in it, nor do we see that it has an end; but we do see before us many yards of ground, still more miry than any we have yet passed. We must wade through this, however, before we lay down the pen; and then we will mark the spot, leap the fence, and rest for a week, at all events. A parochial medical officer does not retain a district for one month, before he secures the acquaintance of a large class of invalids, who can receive no medical relief but through parochial charity, and whose cases are not such as to demand absolutely an "order" from the "relieving officer". Some persons may tell us that the medical man is doing more than is his duty, in attending to these applicants without official command. Such persons can and do know nothing whatever about the matter. The parochial medical officer must attend to the class of applicants to whom we refer: his own good heart impels him to it; for how can he, with the feelings of a man in his bosom, oblige every poor old patient that applies to him for "a box of pills and a bottle of cough mixture"; to drag his or her wearied limbs some miles, perchance to obtain at last, amidst a torrent of insult, "an order" from what the law calls the "relieving officer", who too often is a low, snarling, heartless wretch, that might pass current as the hybrid produce of Caliban and a female Cerberus.

But more; if the medical officer were disposed to force the "order" in the class of cases of which we now speak,

he could not; for he would know well that such a line of conduct would do hurt to the benevolent feelings of the public, against which no man can rebel so little as the doctor. Oh, no! such a proceeding is impossible. The poor would howl at it; the trader would cut off his respect; his worship at the hall, and the clergyman, would frown and hold back greeting.

It is impossible to say what amount of medical relief is afforded to the poor by the union practitioner, without being recorded; but it is enormous. It is at least three times greater than that stated in the returns. And when this is considered, the salary of the parochial officer becomes so infinitesimally small, that a homœopath might examine it, and find it inadequate to cover such a yearly drug bill as he even would require for parochial medicines alone.

We reserve some further observations on the late parliamentary discussions for our next number; and conclude now by remarking, that if one subject shows more powerfully than another the importance of a fair representation of medical men in parliament, it is the subject which we have discussed on this occasion with so much licence and unhidden disgust.

THE "NORTH WALES CHRONICLE" AND THE NORTH WALES BRANCH OF THE ASSOCIATION.

THE Editor of the *North Wales Chronicle*, Mr. Augustus Robert Martin, has sent to us, for publication, a very violent MS. denunciation of Mr. Lloyd, and a more general printed attack upon the profession in North Wales. We do not feel that it is necessary to defend Mr. Lloyd; and therefore we refrain from giving space to a document which we could not insert unless we accompanied it by an exposure of its unscrupulous character.

Independent of the reason just stated, we conceive that the following paragraph is a sufficient justification of our silence upon the present occasion. If our "productions are not worthy of any serious notice" in the columns of the *North Wales Chronicle*, of course it cannot greatly distress our editorial brother to be informed that we decline to insert his "productions" in this Journal. From the last sentence of the subjoined extract, it appears that Mr. Martin considers himself a pretty good prophet.

"We have seen the attack upon us in the Journal of the Provincial Medical and Surgical Association; but as we have no doubt whatever that Mr. Lloyd has for the nonce acted as editor, reporter, and correspondent, the productions are not worthy any serious notice in these columns. His animus towards the *North Wales Chronicle*, since he was refused the opportunity of using it for the display of his malignity towards other professional men, is sufficiently well known in the neighbourhood, and we have no apprehension that his statements will be believed beyond his own small coterie. It will be surprising to us if his services to the Association do not soon lead to its dissolution.

SECOND READING OF THE VACCINATION EXTENSION BILL IN THE HOUSE OF COMMONS.

WE record with sorrow and amazement that Lord Lyttelton's Bill was read a second time, without a division, at a forenoon sitting of the House of Commons, on Wednesday, the 20th instant.

The discussion which took place was short, but ominous of evil. It is thus reported in the *Globe* of the same day.

"Sir JOHN PAKINGTON moved the second reading of the Vaccination Bill, and entered into a great many statistics to shew the practical difference in the rate of mortality from small-pox between countries where vaccination was by law compulsory and countries where it was left optional, establishing the conclusion that the rate of mortality in the latter was nearly double what it was in the former. It was proposed to make vaccination compulsory by this bill, and he hoped the House would adopt the principle.

"Lord PALMERSTON was prepared to support the principle of the bill, but its machinery required alteration. He would, however, vote for the second reading.

"Mr. BRADY opposed the bill as inefficient for its object, and impracticable in its details.

"Sir GEORGE STRICKLAND objected to the bill, and thought they ought to adopt the voluntary and not the compulsory principle. By the bill they were to force parents to send children for vaccination, and on that ground he opposed the bill.

"Mr. FREWEN also opposed the second reading.

"The bill was then read a second time without a division."

It yet remains for the House of Commons to discuss the Bill in Committee, so that some chance exists of frustrating the unfair and injudicious attempt which is now being made to hurry this radically bad measure through Parliament. Granting, even, that the compulsory principle be a good one, the machinery by which it is proposed to carry it out is pregnant with many and vast evils, as we have already fully shown. We trust that a last but resolute effort will be made to arrest the progress of the Bill. Let every reader of these lines, who is hostile to the measure, express strongly by letter his opinion to his representative in Parliament, and to any other Member of the House of Commons with whom he may be acquainted. Much benefit may yet result from the general adoption of such a course. Let petitions for delay also be sent in from those places which have not petitioned.

It is indeed strange beyond measure, that Lord Palmerston should be so fastidious as to the promotion of medical reform, so long as there is not perfect unanimity among rival medical corporations; and that he should at the same time be quite content to allow the profession to be injured by obnoxious legislation, in a matter regarding which there is no cause for haste, and many reasons against endangering the extension and the efficacy of vaccination by the precipitate and random legislation which is now being attempted.

ORIGINAL COMMUNICATIONS.

OPERATION AND RESULTS OF QUARANTINE
IN BRITISH PORTS SINCE THE BEGINNING
OF THE PRESENT CENTURY.

By GAVIN MILROY, M.D.

*(Read before the Epidemiological Society, June 6th, 1853.)**[Continued from page 622.]*

I HAVE next to consider the relations of quarantine to yellow fever. Various circumstances within the last few years,—more especially the case of *H.M.S. Eclair*, the recent publication of an Official Report on the disease by the General Board of Health, and the still more recent occurrences connected with the arrival of the West India mail steamers at Southampton—serve to give much interest, at the present time, to this part of my inquiry.

Fortunately, there is not any lack of evidence upon the subject; and although, as usual, there has been on most occasions no little discrepancy of statements, not to say of opinion as to the bearing of the statements, it will be easy to steer clear of controversy by appealing, almost exclusively, to the testimony of those writers, who have been the most zealous upholders of quarantine as a trustworthy defence against the invasion of the pestilence under consideration.

I select the visitations of Gibraltar, as affording perhaps the best means of testing the point. Since the beginning of the present century, Gibraltar has been five times the scene of epidemic attacks of yellow fever; viz:—in 1804, 1810, 1813, 1814, and 1828. These successive occasions present a singularly favourable opportunity for careful investigation; and as the Rock is all but separated from the mainland of Spain—being connected with it only by a narrow sandy isthmus which is easily watched—it may be regarded, for our purpose, as strictly insular, with every facility for complete isolation and rigorous quarantine. During the first three years of the century, yellow fever had prevailed in several towns on the southern shores of Spain, especially in Cadiz, Malaga, Alicante, and Carthagena. There was a recurrence of it in the following year.* In consequence of the great dread of the disease at Gibraltar (which had hitherto escaped), a most stringent quarantine had been perseveringly kept up against all arrivals from the neighbouring infected or suspected ports. Sir William Pym was then the quarantine officer of the harbour. In the month of July, he left his post on leave of absence, and did not return till the middle of October, when he found that yellow fever had fairly broken out in the town. The earliest suspicious cases had been observed about the beginning of September, in a notoriously filthy and unhealthy spot on the Rock; and to this spot the disease was for some time confined. The disease then rapidly spread, and eventually caused an immense loss of life. In less than three months, 6000 persons, out of a population, including the troops, not exceeding 16,000, perished. By the end of November, the pestilence had greatly abated; and it ceased entirely before the end of the year. As to the manner in which the pestilence has been alleged by some parties to have eluded the vigilance of the quarantine establishment, the following explanation is proposed by Sir William Pym,—not however, be it remarked, as the result of his own personal inquiries on the spot, but merely on the oral authority of one of the medical officers of the artillery, forming part of the garrison:

"A shopkeeper, named Santos (who resided in Boyd's Buildings), arrived from Cadiz on the 28th of August, 1804, and was taken ill on the 29th; he had lodged in a house at Cadiz, where some persons died of the then prevailing fever.

Mrs. Fenton (wife to bombardier Fenton, of the Royal Artillery) was the second person attacked; she was taken ill on the 3rd of September. Her husband and a child of the name of Roland were taken ill on the 8th, and died on the 12th. Mrs. Boyd, who had visited Mrs. Fenton, was taken ill on the 13th, and died on the 19th; her husband was taken ill on the 14th, and died on the 16th. All those families were neighbours. The disease was confined for some time to this particular part of the town, and to those who had intercourse with them."

Such a loose unconnected statement as this can scarcely be received as evidence to prove anything beyond the alleged date of the first case, and the circumstance of the disease being limited for some time to the locality where it first appeared, and which is known to have been the most filthy and insalubrious on the "Rock". No intercommunication, it will be observed, between the first and second cases is even so much as mentioned; the connexion of the one with the other is merely guessed at. Unless medical evidence on so important a point of inquiry as that of the introduction of a pestilence be different from such a specimen as this, I fear that it will never command public confidence or respect.

Fortunately, there is another historian of this epidemic, Sir J. Fellowes, who was at Gibraltar during the greater part of its prevalence. Sir James, it is to be remembered, was a most zealous upholder of the contagion of yellow fever, and of the necessity of strict quarantine measures for its exclusion. His testimony is, therefore, the more valuable. Now, from his work, it clearly appears that there was no recognised or known yellow fever in Cadiz either at the time when the man Santos was there or when he left it; and moreover, it is certain that he obtained a passport from the British Consul there, before he went on board the vessel in which he took his passage for Gibraltar. The vessel too, it seems, remained quite free from sickness. All, therefore, that can be made out is simply that a man, arriving in apparently good health, at the usual sickly season—in a year, too, characterised by remarkable atmospheric distemperatures—went to reside in a confined and crowded house, in a notoriously filthy locality of a very unwholesome garrison town, and that, within a few days subsequently, he had an attack of fever, from which he recovered; also, that other cases of fever occurred immediately afterwards in the immediate neighbourhood of the said locality.

It must not, moreover, be omitted to be mentioned that Sir James Fellowes had pretty strong grounds for believing that a fatal case of fever had occurred ten days before the man Santos' arrival, in the person of a smuggler from Malaga, who, if the authenticity of the case is to be admitted, must also have managed to have evaded the regulations of the port. Whatever view be taken, it is, at all events, quite obvious that the quarantine precautions failed in giving that security to the town which it was their object to impart.

Dr. Nooth, who acted as health officer of the harbour during the temporary absence of Sir Wm. Pym, as well as many other medical practitioners in Gibraltar at the time, and of the ships of war in the bay, were of opinion that the disease was of local development, and that foreign importation had nothing to do with it. It should always be borne in mind that there was not, perhaps, a more unwholesome garrison town in the British dominions than Gibraltar was then, and continued to be for many years afterwards. The unnecessary sacrifice of life among the troops there, not to mention the civil population, during the first fifteen years of the present century, must have been enormous.

After the cessation of the severe visitation of 1804, the Rock remained free from the pestilence in an epidemic form for the next five years and a half, although occasional cases of the ordinary endemic fever of the place, accompanied with a dark yellow suffusion of the surface and sometimes also with black vomit, occurred in most years, even when the garrison was declared to be healthy. During the whole of this time, the Spanish ports, which had suffered so severely during the first four years of the century, were equally exempt. This cessation or lull in the course of

* It may be worthy of notice, as indicating a wide spread sickness in distant parts of the world, that in 1804 the yellow fever was extremely prevalent in the West Indies, and caused very great mortality among our fleet, etc. Between seven and eight hundred died of it in the naval hospitals of Jamaica and Antigua alone, during this year.—Sir G. Blane's *Observations*.

pestilential visitations, is a very suggestive and significant fact in epidemiology; and the fact is the more important as regards our present inquiry, as, during the very same period that the yellow fever disappeared from the southern shores of Spain, not only (as already mentioned) was epidemic plague absent from Egypt and Turkey, but there was also a very remarkable diminution of typhus fever in England at the same time. Whether there be any connexion between these coincident occurrences in distant countries, is a question of the utmost interest, but one as yet nearly quite unexplored.

In the summer of 1810, yellow fever re-appeared in most of the Spanish seaports which had been previously affected; nor did Gibraltar escape. The atmospheric peculiarities of the season were very similar to those which had been observed in 1804. Upon this occasion, it was believed that the disease was imported from Carthage, as it was thought to have been on the former occasion from Cadiz. The facts related by Sir W. Pym, who was the quarantine officer of the port at the time, are these. Four transports, with deserters from the French army, arrived from Carthage on the 19th of September. One man had already died from the fever on board one of the vessels, and there were several others seriously ill. The transports were anchored at least half a mile from the shore, and kept under the strictest quarantine. Sir W. Pym applied to the Governor to send them off to Minorca, as there was a lazaretto on shore there, and there was not one at Gibraltar. But this severe measure, very fortunately, could not be carried into effect. Sir W.'s narrative proceeds: "During the time that the disease had been going on on board the transports in the bay, the garrison continued in perfect health till the 20th of October, when, in consequence, as I must suppose, of a breach of quarantine regulations (which, however, could not be detected), a Minorcan family, in the south district, belonging to the dockyard, was attacked with the disease." A story was afterwards circulated, that some intercommunication had taken place between the person first attacked and the transports; but it could not be substantiated; and, as Sir W. Pym himself candidly admits that the pestilence found its way into Gibraltar through some undiscovered channel, while a most rigid quarantine was maintained all the while under his own directions, it is scarcely necessary to dwell any longer on the subject. Most of the medical practitioners on the Rock considered it to be of local and indigenous origin. It will be observed, too, that the fever again appeared about the same time of the year; and Sir W. Burnett, who was then principal medical officer of the Mediterranean fleet, mentions that, after very heavy rains in September, which had brought down a prodigious quantity of putrid decomposing matter from the upper parts of the town to the beach, the weather had set in very warm, with a prevalence of the oppressive easterly wind. Dr. Hennen states that, in the months of July and August, bilious remittent fever was more than usually prevalent in the town, and that the type of the disease became more malignant and fatal in September.

It may not be undeserving of passing notice, that some of the physicians in Carthage alleged that their epidemic in 1810 was brought to them from Gibraltar; while the quarantine authorities of the Rock attributed their visitation to their Spanish neighbours. This sort of mutual incrimination is far from being infrequent in the history of quarantine.

The next time that yellow fever broke out in Gibraltar was in September 1813—the year, it will be remembered, of the plague in Malta. This epidemic proved much more fatal than the preceding one. Sir W. Pym, who was still at the head of the quarantine department there, states that "it was again traced to importation"—"that the individuals who brought the disease into the garrison were ascertained"—"that one of them was ill when he arrived"—

"that the disease was communicated to the persons residing in the same house, and speedily on both sides of the street in which the house was situated". Unfortunately, he has omitted to give any particulars respecting these several allegations; nor does he state who were the parties that brought the disease, or whence they came, or when they arrived. We are necessitated, therefore, to look elsewhere for information as to the origin of this epidemic; and, happily, there is good evidence at hand. That most truthful writer, Dr. Hennen, who, when principal medical officer of the garrison, examined with great care all the official documents in the public archives touching the previous epidemics, states that cases of the disease had occurred a couple of months prior to the date assigned to its appearance by Sir W. Pym. "One neighbourhood", he says, "viz., *Boyd's Buildings*, was, as usual, the theatre where the disease made its early appearance in the town; and, on the 6th of July, Mr. Frazer met with a case of highly suspicious fever, which proved rapidly fatal: there is little doubt that it was a genuine instance of that fever which afterwards committed such ravages." The accuracy of this important statement is verified by Sir W. Burnett and by Mr. Amiel; who, with all other writers on this epidemic, have alluded in the most emphatic manner to the notoriously unwholesome condition of the town of Gibraltar at the time, from the excessive crowding of the population, and the horribly filthy state of the lanes and houses, aggravated, as on former occasions, by the continued prevalence of easterly winds.

It is scarcely requisite to specify the stories that have been related by those who seem to imagine that, whenever a disease, which is only of occasional occurrence, appears in a place, it must necessarily have been introduced by some person or another, forgetting all the time that the atmosphere is the readiest vehicle of all. One of the rumours was, that the pestilence had been brought from Cadiz, by a vessel which arrived in the bay on the 11th of August: but, upon referring to Sir James Fellowes's history of the fever of that year in Cadiz, where he was the principal medical officer of the British garrison at the time, it appears that the earliest recognised cases there were not observed before the beginning of September. His words are: "Early in September, I heard that a suspicious case of fever had occurred in the well known *Barrio de Sta. Maria*"; the very locality in Cadiz where the disease first showed itself in 1800, and again in 1804. Sir James does not so much as even hint the idea that the disease had been this year imported into Cadiz *ab extra*. Moreover, Mr. Frazer, who was at the head of the medical staff in Gibraltar at the time, candidly admitted, notwithstanding his decided opinion as to the contagiousness of the disease, that he had great doubts as to its importation in 1813.

It was upon the cessation of this epidemic, that the series of queries, which elicited so large an amount of valuable information respecting the sanitary state of Gibraltar, was addressed by the medical department of the army to the medical practitioners, civil as well as military, on the Rock.

In the following year, during the autumnal season, there was a fresh outbreak of the disease. It has never been alleged, as far as I know, that, upon this occasion, importation from abroad had any share in its development. The early cases appeared in the filthy, crowded localities, affected in former years.

After 1814, Gibraltar remained exempt from any epidemic visitation of yellow fever till 1828, a period of fourteen years; although sporadic cases, having all the characters of the true pestilence, occurred now and then in the autumn months. It was in 1828 that the plague prevailed in various parts of Greece, and in Wallachia, Moldavia, and other countries in the north of European Turkey. The Russian army, engaged at the time in war with the Turks, experienced disastrous losses from the ravages of the disease. At Gibraltar, the yellow fever appeared about the same season of the year as upon all the former visitations—a circumstance that is highly suggestive in an epidemiological point of view. The earliest cases occurred about the

* It deserves to be noticed, that in consequence of the known presence of the plague in Malta this year, the vigilance of the quarantine authorities at Gibraltar was even greater than usual.

beginning of August. Dr. Hennen was the principal medical officer of the garrison at the time; he was also health officer of the port. Unfortunately for medical science, he fell a victim himself to the fever. He left, however, very ample notes respecting the circumstances connected with its development; and his son, who edited the valuable work on the *Topography of the Mediterranean*, informs us that his father had quite satisfied himself that the disease could not be traced to importation. Sir Wm. Pym (who then occupied the post which he now fills) was sent out by the Colonial Secretary of the day, Sir George Murray, to examine into the history of the epidemic, at the head of a commission appointed for the purpose. He appears to have come to the same conclusion, if we may judge from the following statement in his book respecting the vessel which was at first suspected to have brought the pestilence from Havanna;—"I think it right", says Sir W., "to state, that there was no evidence to convict her, and that I stated my opinion generally that she ought not to have been under suspicion, as she underwent the regular period of quarantine, and was released therefrom in the regular way, with the approbation of the Inspector of Health in the quarantine department, and by the authority of the Lieutenant-Governor."

We have thus seen that, during little more than the first quarter of the present century, Gibraltar was five times the scene of epidemic yellow fever, notwithstanding the utmost vigilance of the quarantine department there, and the stringency, not to say severity, of the precautions taken to exclude the disease. That the most rigid measures were enforced, will be pretty manifest from the following particulars, related by Sir James Fellowes.

In Jan. 1811, two English transports, with between four and five hundred German recruits on board from Carthage, were kept under quarantine for upwards of a month in the bay, without being allowed to communicate with the land. It does not appear that there was any actual disease on board; but they had come from a suspected port. They were then sent on to Cadiz, at that time in the possession of the English army. On their arrival there, although the men were still free from sickness, they were not allowed to be landed at once; and as, unfortunately, the weather became very tempestuous, the soldiers were obliged to keep below in the between decks, most of the time. "When the weather moderated, every assistance was afforded them; but it proved that, during the few days that the hatches were covered over in consequence of the heavy rains, a complete typhus fever* had been formed; that the men (who appeared to be well while they had been kept on deck constantly, and the fresh air had been allowed to pass through the ship) were falling down with a malignant disorder, the germs of which, it was evident, had been brought by them from Carthage, and had exploded into fever in the vitiated air by which they were surrounded in the close and crowded between decks."

There were upwards of one hundred already attacked. Prompt steps were at once taken by Sir J. Fellowes to separate the healthy from the sick. Four hundred, after due ablutions and change of dresses, were landed and sent to a temporary hospital, a mile from the town; while one transport was entirely evacuated, and after being thoroughly cleansed, ventilated, and fumigated, all the sick were removed into it. Eventually, all the sick were brought ashore. Due precautions were taken to prevent communication between the sick of the troops in the garrison and the inhabitants of the town; and although a good many deaths had taken place in the hospital, and more than two hundred in all had been attacked with this "highly contagious disorder", it at length ceased, without any detriment to the public health, either of the other shipping in the bay, or of the population on shore.

From Gibraltar we now pass on for a few moments to the rocky island of Ascension, in the Atlantic Ocean, about

seven or eight hundred miles from the coast of Africa. Its latitude is about 8° south of the equator, and its longitude is 14° 28' west. It is resorted to by shipping for refreshment and watering; but the island itself is entirely unproductive. Our ships of war upon the African station, when they have become sickly, often visit it. In 1823, soon after the arrival from Sierra Leone of the *Bann* frigate, which had lost many of her crew during the voyage, yellow fever broke out in the small garrison, and committed considerable ravages. As no quarantine restrictions had been adopted towards the ship, it has been generally believed that the disease on shore was directly introduced by the *Bann*. Sir William Burnett, who was sent out by the Admiralty to examine into the particulars of the case, and afterwards published an exceedingly interesting narrative on the subject, leaned to this view of the question; but he did not hesitate to avow, at the same time, that the evidence was not without some defective links. The circumstances were, however, so suspicious that, in future, ships arriving at Ascension with malignant African fever on board were directed to be detained for some time in quarantine, before having free communication with the garrison. Notwithstanding this precaution, there was a partial outbreak of the disease among them in 1838, several weeks after the arrival of the *Bonetta* in a sickly state from the African coast. The surgeon of the garrison regarded the distemper as of local origin; and Dr. Bryson, (in whose valuable work the particulars will be found), while he is of opinion that it was imported, nevertheless admits the impossibility of tracing the mode of its introduction, after all the pains he had taken to discover it.

The mention of the African station in connexion with yellow fever and quarantine, naturally brings to our minds the sad case of the *Eclair* in 1845, in as far, at least, as its history bears upon our present subject. It will be remembered that, in consequence of the crew becoming very sickly at Sierra Leone, it was deemed advisable to leave the coast and go to Boa Vista, one of the Cape de Verde islands; and that, while there, her sick were landed upon a small islet in the harbour, but that the disease nevertheless continued to rage with great severity. The result was that after a short stay all were reembarked, and the *Eclair* proceeded on to England, where she arrived at the Motherbank, after a run of fifteen days from Boa Vista, on the 28th September. Already upwards of one half of the crew had perished since the commencement of the sickness in July, and every day added fresh victims to the list. It is needless to say that the utmost alarm and depression existed among all on board. The surviving medical officer urged the immediate landing of the crew, as the only means of arresting the terrible ravages of death; and Sir John Richardson, the physician of Haslar Hospital, expressed his readiness to receive them into the wards of that noble institution,—an advice that was cordially seconded by Sir William Burnett. Had this step been taken, much distress would have been spared, a heavy expense avoided, and, what is of far greater consequence, several valuable lives might have been saved. But, unhappily, the fears of our quarantine authorities prevailed over their judgment. The unfortunate remnant of the crew were doomed to rigid confinement within the walls of the pest-smitten ship; and this, too, in sight of the shores of their own country. After remaining three or four days in close quarantine at the Motherbank, the *Eclair* was ordered round to Stangate Creek, before either the sick or the unattacked were removed from her, but not till many fresh attacks and several deaths had occurred. She was not released from quarantine till the end of October, or five weeks after her arrival in England. It is altogether painful to look back upon the sad history of this vessel. The serious errors that were committed with respect to the management of the sick at Boa Vista, were only outdone by those that were perpetrated after her arrival off our own coast. The case made a deep impression on the mind of the medical public; and it was hoped that a more judicious practice would in future be adopted by our quarantine authorities, in the event of a similar occurrence.

* From other statements in the narrative, it is obvious that the disease was genuine yellow fever.

The proceedings which have recently taken place at Southampton, in reference to the mail steamers arriving from the West Indies, seem to indicate that the system to be pursued is essentially the same, although some of the details may be modified. It is, indeed, not easy to ascertain the principles upon which the course now adopted is based. The mail bags are landed *instantly*, while the passengers and crew are detained on board. Pratique is at once given, although men may be dying of the disease on board at the time, provided only their seizure took place six days (ten were at first deemed necessary) before arrival. A health officer goes on board an infected ship, and returns on shore himself, while he leaves the ship and all on board (the mail bags always excepted) in quarantine. At one time, not only the bedding of the sick, but everything which may have come in contact with them, is recommended to be burned; and then the corpses of persons, who have died on board of casual diseases, have been ordered to be taken out several miles to sea and buried there, before the vessel is permitted to come into port. Surely, such steps as these can serve but to spread alarm and bewilder the public mind, while they can give no real protection to the public health.* And be it remembered that, at the very moment when all this was going on towards the mail steamers at Southampton, the authorities at Port Royal, Jamaica, were receiving without delay or hesitation the sick from H.M.S. *Higflyer* into the naval hospital there;—that the wards of the public hospital at Kingston were open to the sick from the ships in the harbour;—and that, at Barbadoes, the suffering crew of H.M.S. *Dartless* were at once landed and conveyed to the military hospital. With such facts before us, is it not high time that our quarantine system be looked into, with the view not only of bringing its regulations into harmony with the results of well attested experience, but also of establishing something like uniformity in its requirements?

It remains now to invite your attention to the relation between quarantine and the Asiatic cholera.

The whole history of this formidable pestilence is so interesting and instructive on all points of epidemiological inquiry, that it must ever occupy a very prominent place in every attempt to ascertain the laws which influence the development and diffusion of wide spreading diseases. No epidemic, moreover, has been so minutely and extensively observed, and of none have we such varied and thoroughly trustworthy records. We can trace its career almost step by step, and with something of the connected sequence of an historic narrative, from the time when it first—after having been for ages, for all that we know to the contrary, limited to one district of Asia, viz., Hindostan—began to assume the character of a great migratory pestilence, and go forth, at the bidding of Almighty Power, upon its mission of warning and judgment, to the ends of the earth. Its course and progress can be followed on the map as we follow the track of any of those hordes of the human race which, breaking loose from their place of long abode in some remote corner of the East, spread themselves of old over the face of the European continent. We can mark the advances of the invading foe from country to country; we can tell how long it was upon its successive marches; the dates of its arrival in different parts, the rapidity of its movements, the length of its stay, the places which it ravaged, and the very districts in each place upon which its chief fury fell. We know the means that were taken in every country that was invaded to avert the stroke, to keep the enemy out, or to resist its progress and mitigate its ravages; and we know, too, the amount of success or benefit which attended the efforts that were made. We know that the Russian government, in 1831, having tried quarantine, and other like mea-

sures, to protect different parts of its dominions, speedily found their utter inefficacy, and abandoned all attempts of the sort; that the Austrian Emperor formally declared that his government "had committed an error in adopting the vexatious and worse than useless quarantine and cordon regulations against cholera", frankly admitting that it did so before the nature of the disease was rightly understood; that Prussia, too, having in vain tried the same expedients, was forced to give them up; that in our own country measures of the most extraordinary stringency to prevent the introduction, and to arrest the spread of the pestilence, were at first recommended and attempted to be carried out, and that they proved so utterly valueless that they were promptly discontinued, and the government of the day intimated, in the speech delivered from the throne, more than incredulity as to their use or expediency; that the French Academy of Medicine formally declared their opinion to the same effect; and that transatlantic experience, both in the United States and in Canada in 1832, testified to a similar result. We know that, in the following year, the disease found its way into different ports of Spain, notwithstanding a rigorous quarantine; that, in 1834, it eluded the vigilance of the health officers at Gibraltar, as yellow fever had done in former years; also at Stockholm and other ports in Sweden, whose former immunity had been attributed to the stringent precautions of defence which had been taken; that, two years subsequently, Genoa, with its well appointed lazaretto and numerous quarantine staff, failed in its attempt at exclusion; and that Naples and Rome were equally forced to acknowledge the impotence of all their efforts. Nor was Malta more fortunate. Hitherto it had escaped, in consequence, many persons believed, of its insular position, and the strictness and efficiency of its quarantine establishment; and its exemption at a time when the pestilence was in Egypt on its one hand, and in Gibraltar and the south of Spain on its other, might certainly, with some show of reason, lead those, who form their opinions of epidemic diseases from the observation of what is going on in one or two limited localities, to this conclusion. But dismal experience now baffled the fond expectation, and proved the insecurity of the trusted means of defence.

Such were the lessons taught by the first world-wide migration of Asiatic cholera. After 1837, the pestilence ceased from the face of Europe for the next ten or eleven years—although scattered cases occurred every now and then in the various countries which had been affected, and a certain choleraic impress, so to speak, on the character of febrile and other diseases continued to be frequently observed.

The dark cloud once more appeared in the eastern horizon in 1845. Ere long, it became larger and more threatening, and steadily advanced in its march of destruction westward, following pretty nearly the track of its former career, and setting at defiance all mechanical attempts at exclusion where these were again attempted. Again did the quarantine authorities of this country issue some detentive regulations against vessels arriving from infected or suspected parts on the continent; but these, as you will probably all remember, were promptly abrogated, upon the recommendation of the General Board of Health, then recently instituted. The policy of this step was fully recognised by the London College of Physicians, whose well considered opinion stands in the following words:—"Cholera appears to have been very rarely communicated by personal intercourse; and all attempts to stay its progress by cordons or quarantine have failed. From these circumstances, the committee, without expressing any positive opinion with respect to its contagious or non-contagious nature, agree in drawing this practical conclusion, that in a district where cholera prevails, no appreciable increase of danger is incurred by ministering to persons affected with it, and no safety afforded to the community by the isolation of the sick." The Report of the Commissioners of Health in Ireland on the cholera epidemic of 1849-50 proclaims the same very important practical conclusions; and the medical authorities in Scotland have, I believe, emphatically recorded their opinions to a like effect.

* Besides the precautionary measures alluded to above, it has been stated in the public prints that an order was issued by the Admiralty, prohibiting the reception on board of any of the West India mail steamers, on their homeward bound voyage, of yellow fever invalids, or of any distressed British subjects supposed to be labouring under, or recovering from, attacks of the disease. The cruelty of such an order is strongly commented on by Dr. Cummins, surgeon of the *Medway*, in the *Lancet* of May 28, 1853. If such an order has really been issued, it has not, I am assured by Sir William Burnett, proceeded from the Admiralty.

After such concurrence of judgment among the medical profession in this country, it is unnecessary to allude to that of our brethren abroad. It is all but unanimous; except, perhaps, in Spain and the Italian States, where other motives, besides those of truth and conviction, are well known to influence the judgment of officials upon such matters. Nor is it undeserving of notice that, although these countries profess to place the greatest reliance on quarantine measures, and certainly carry them out with the greatest rigour, the experience of the recent epidemic has again shown their inefficacy against its invasion.* Malta, which, although a British island, may be regarded as truly Italian as regards her quarantine establishment, was again visited with cholera in 1850.

As far as I am aware, it has not been alleged by any person that it was then imported by shipping. Nor have the endeavours of the Spanish *guardas* to keep out the pestilence from Cuba, where the quarantine regulations are of the utmost stringency, been more successful. This was the only island in the West Indies that suffered during the first epidemic in 1834. In 1850, the enemy again found its way in by some channel that has never been discovered; and you will perhaps remember that, in the paper which I had the honour of reading before this society last year, I showed that the development of the pestilence in Jamaica towards the end of the same year could certainly not be traced to any neglect or violation of the quarantine, to whose agency the immunity of the island during the former epidemic had been ascribed.

Notwithstanding these facts, such is the dread of this plague in countries which have hitherto escaped its visitation, and such has hitherto, from long habit, been the vague and general belief that new diseases may be kept out by a system of rigorous medical police, just as interdicted articles of merchandise may be excluded by custom-house officers and coast guards, if these men will but do their duty, that the most extraordinary measures have been resorted to, in different places, within the last year or two for the purpose of presumed self defence. For example, two years ago, at Demarara, a quarantine of forty days was imposed upon one of our ships of war, crowded with troops too at the time, simply on the ground that she had come from Kingston in Jamaica, although no disease existed in that town at the date of her departure, nor had a single case of sickness occurred on board during the voyage. This was, certainly, a precaution with a vengeance; and might, I need not say, have led to the most disastrous consequences to the unfortunate *detenus*, had not the captain wisely determined to go to another colony, where he might communicate with the shore, until the appointed time had expired for the landing of the troops at Demarara.

Something of the same sort recently occurred also at the island of Mauritius; so that you see what views are being still entertained, and acted upon too, by some of our own countrymen abroad. Let us not, therefore, boast too much of our superior enlightenment in matters such as that now under consideration, or be so prompt, as we are apt to be, to rail at the ignorant obstinacy and blind prejudices of foreign states, in refusing to go along with us in effecting the reform of various practices, however opposed these practices may be to the conclusions of scientific research and the acknowledged results of experience. Let it be remembered that the inconsistencies of our own Government have been often so flagrant, that foreigners may well call upon us to look at home, instead of setting ourselves up as their guides and instructors. They may remind us that, after two formal declarations of the inefficacy of quarantine to avert the cholera, an order was issued, no farther back than last September, from our Council office, reimposing what was called a "Quarantine of Observation" in our own harbours on vessels, on board which was "any person or persons actually suffering from cholera, or who had been

suffering from that disease within the five days previous to the arrival of the vessel in port";—such persons to be detained on board the vessel, and the vessel to be kept in quarantine "for such period as the medical officer employed to visit the sick might judge necessary for the security or preservation of the health of the community on shore."

In drawing these remarks to a close, I cannot but again strongly commend the subject of quarantine to the searching inquiry of the medical profession. That the system hitherto pursued stands in need of a thorough revision, and of some important changes, cannot, I think, be questioned by any one. I have already occupied too much of the time of the society to dwell upon these points at present; and it is the less necessary to do so, as I have explained my views at some length in the Report on the Cholera in Jamaica and on the sanitary condition and wants of that island, addressed by me in the course of last year to the Colonial Minister.

Fitzroy Square, June 1853.

CASE OF PULMONARY DISEASE: EXUDATION DEPOSIT BETWEEN THE LUNG AND PLEURA.

By P. MARTIN DUNCAN, M.B.Lond., Physician to the Essex and Colchester Hospital.

(Read before the Suffolk Branch of the Provincial Medical and Surgical Association, June 24, 1853.)

THE following case excited much attention amongst the medical men in and about Colchester, on account of its interesting and somewhat anomalous character.

A tall and thin, red-haired labourer, aged 22, the son of unhealthy parents, and the brother of some very phthisically disposed individuals, came under my care as an in-patient at the Essex and Colchester Hospital, in March 1850. He had never had very good health, and for some weeks had suffered, from cough, a sensation of uneasiness, never amounting to actual pain, in his right side, and from gradually increasing dyspnoea. The cough was occasional, and not very severe in its duration; but, from its being induced by the slightest exertion, it was very inconvenient to him; the expectoration was small in quantity, saline to his taste, and mucoid. He had become emaciated to a considerable extent before his admission into hospital, and was troubled with a harsh, hot skin. On examination, I found that his countenance denoted a depressed state of his general powers; his eyes were sunken, and the pupils dilated; his hair was harsh and dry; and the *ala nasi* were in constant action. He never complained of headache, or of any nervous symptoms. The general muscular development was very low, and he had large ends to his long bones, clumsy joints and clubbed ends to his fingers, and a narrow chest. Any unusual exertion fatigued him, and greatly increased the number of the respiratory efforts, and the pulsation of his heart. The thorax expanded very unequally during inspiration, and the abdominal muscles assisted in an abnormal manner. The right side of the thorax was seen to expand less than the left during inspiration; and this expansion was sudden, and not progressive: still, there was no very great difference between the two sides. The measuring tape determined that the right was half an inch larger than the left side of the thorax. Measured by Quain's stethometer, the infraclavicular region of the right expanded only five degrees less than the corresponding region of the left side. Hutchinson's spirometer proved that the patient's capacity for respiration was forty-five per cent. below the average. There was no bulging of the intercostal spaces on the right side; and the care which was taken in this physical examination was determined by the peculiarity of the results of percussion and auscultation. The whole of the right side of the thorax was dull on percussion—very dull; in fact, the upper margin of the liver could not be distinguished from the adjacent lung; the left side was resonant, and had none of the

* Professor Sigmund informs us that, in 1849, the disease made its appearance in Naples, Brindisi, Leghorn, and Genoa, in all of which places quarantine was maintained against its introduction; while Civita Vecchia, where no quarantine existed, escaped altogether.

sense of resistance to the finger possessed by the right side of the chest. The dullness was less over the track of the larger bronchi, but the clavicle, on percussion, yielded a dull sound. The vesicular murmur was rude and puerile over the whole of the left side, and feeble and yet perfectly audible over the whole of the right. There was slight excess of bronchial breathing in the infraclavicular region of the left side towards the median line, but on the dull right side there was no such excess. The only stethoscopic sign was a marked diminution in the intensity of the vesicular murmur. On coughing, wheezing sounds were occasionally heard in the scapular region of the left, but not on the right side. The vocal fremitus was well marked on the left side, and could be satisfactorily distinguished over the whole of the right side: it was not more intense in one spot than in another. There was no ægophony, bronchophony, or any vocal evidence of condensed lung. There was no creaking or friction sound on the right side, and the heart appeared to be healthy and *in situ*. The pulse, however, was 120, and increased rapidly whilst the examination proceeded. The respirations were from 38 to 45 in a minute. The liver and spleen were within their regional limits; and the abdominal viscera appeared to be in a normal condition. The tongue was rather glazed, and the gums spongy; the appetite was tolerable; there was no great amount of thirst; the bowels were constipated; the urine was said to be scanty and high coloured. As regards the superficial parts, there were no enlarged veins; and the sallowness of the skin appeared to be congenital.

The left lung was evidently performing the office of the right; and the supplementary character of the breathing was indicated by the rude and puerile vesicular murmur. There was no prolonged expiration, or irregular inspiratory sound; but, on the right side, there were the following physical signs, common enough in any other aggregation than the present: dullness on percussion; little loss of mobility; no increase in dimension; faint vesicular murmur; no tubular or bronchial breathing; diminished intensity of vocal fremitus; no ægophony nor rubbing sound.

What was the state of the right lung? That it was grievously affected, there was no doubt. The dullness on percussion and the loss of mobility would indicate pleuritic effusion; but the vocal fremitus was to be felt distinctly enough, and the vesicular murmur was to be heard, contra-indicating that disease. Might not there be thick false membranes between the layers of the pleura? The amount of mobility and the history of the case, the absence of pain and the lack of creaking or rubbing sounds, militated against this opinion.

Condensation of the lung, from tubercle, pneumonia, or any deposit in the parenchyma, was contraindicated by the absence of excess of bronchial breathing, and the diminished character of the vocal fremitus, although the dullness on percussion favoured this view.

For some time after this examination, under the influence of diet and moderate purgation, his intestinal canal became more healthy, his skin altered in its harshness, and his urine less lithic; still, for some weeks, the severity of the chest symptoms increased. Counter-irritation decidedly made him worse; still, there was no enlargement of the right ribs, or tenderness on pressure. He took the iodide of iron and occasional doses of compound rhubarb pill for three months, and improved both as regards his general health and his chest symptoms. The dullness on the right side was as great as ever; but the movement of the side was considerably increased. The vesicular murmur was still faint, and the vocal fremitus a little more distinct.

At this time, I conjectured that the physical signs intimated that there was disease of the pleura covering the lung, not of that lining the side of the chest; and that this disease did not affect the proper pleural membrane, but the cellular tissue between it and the lung—that tissue which is permeated by the blood-vessels which supply the pleural membrane proper.

A general deposit of exudation substance, of lymph, most probably of strumous origin, in this subpleural layer, would account for all the physical signs. Being impervious to air, of less density than the parenchyma of the lung, and general in its distribution, it would produce a dull sound on percussion, and a sense of resistance. For the same reasons, it would allow of a partial transmission of the vocal fremitus; and, as there need not necessarily be false membranes and adhesions between the pleura, the mobility of the side of the chest would only be diminished to a certain extent. The density of the deposit could not be enough to increase the sound of the voice, transmitted through the stethoscope; and it must have been sufficiently dense to prevent the occurrence of the bleating sound. It is most curious, that the right lung should not have suffered from bronchitic or pneumonic attacks. My opinion as to the existence of deposit beneath the pleura was founded on the acoustic phenomena presented by the patient; and, as my interpretation of these might be incorrect, I rarely passed a day without examining him.

The man remained nearly four months in hospital, and then went home, and remained tolerably well for two months. At the expiration of that time, I again saw him. The dullness still persisted, but the mobility of the side was gone, and the dimensions of the right half of the thorax were decreased. The mammary region was drawn in, and the shoulder pulled down. The vesicular murmur of the right side was very faint, and there was slightly tubular breathing. The vocal fremitus was more distinct. He complained of increasing dyspnoea. The left lung appeared to be working well, although there were large *radles* to be heard. The heart was decidedly displaced, its apex beating more than two inches to the right of the left nipple. He had suffered from slight pain in his right side, but there were no evidences of pleuritic effusion. He again left the hospital, caught cold, and became rapidly very ill; his cold led to a bronchitic attack, and his cough never after left him; dullness in the upper part of the left side of the chest, with tubular breathing and increased vocal resonance, supervened, and he died somewhat suddenly, from the bursting of a vomica in the upper part of the left lung.

EXAMINATION OF THE BODY. This was performed with the assistance of Dr. Clark of Colchester.

The chest alone was opened. The right side was greatly contracted; the left much bulged out. On opening the thorax, the right lung was found to be adherent by its pleural surface to the side and to the pericardium; but this adhesion was by no means strong, and it was easily destroyed. The lung was found close to the spine, huddled up in a corner, and no larger than a good sized orange. It was hard and dense, and a section showed carnification, the cirrhosis of Corrigan, with narrowing of the larger, and perfect absorption of the secondary bronchi; and, what was most interesting, there was a layer of semi-organised exudation, external to the altered lung, and internal to the pleura; in fact, between the lung and the pleura covering it. The left lung was studded with tubercles, and a large cavity existed in the apex.

I believe that the loss of mobility, and the subsequent contraction of the side of the chest, were induced by the natural contraction of the deposit of lymph beneath the pulmonary pleura; and that the absorption and condensation of the lung were also produced by the same mechanical causes.

Colchester, July 1853.

TESTIMONIAL. At a Board of Inquiry into the cause of the great sickness and mortality on board the *Ticonderoga* emigrant ship, which sailed from Liverpool, in August 1853, and arrived at Melbourne the following November, the first Surgeon-Superintendent, J. C. Sanger, M.D., was presented of £50, in addition to his pay, in consideration of extra services.

BIBLIOGRAPHICAL NOTICES.

TEXT BOOK OF PHYSIOLOGY. By Dr. G. VALENTIN. Translated and edited from the third German edition by WILLIAM BRINTON, M.D., Physician to the Royal Free Hospital; and Medical Tutor in King's College. [With upwards of five hundred illustrations on wood, copper, and stone.] Part I, p. 1 to p. 320. 8vo. London: 1853.

We regret that the great and accumulating demands upon our space oblige us to abandon our original intention of giving an extended review of this valuable addition to our scientific literature. It is, as we are told in the preface, a faithful translation of "an abridgement, by Professor VALENTIN, of the last edition of his larger systematic treatise, the *Lehrbuch der Physiologie*." The descriptions are clear and complete, and are, moreover, simplified by a profusion of beautiful pictorial illustrations. Whenever it is necessary, the collateral sciences are brought forward to illuminate explanations and reasonings: and so well is this done, that we conceive it to be a feature which demands particular praise.

When the concluding portion of this volume is published, we may return to this work: but, in the mean time, it is incumbent upon us to mention it as a Text Book of Physiology of the highest merit. Though it is peculiarly suited to medical practitioners and medical students, it is also adapted to other educated members of the community, who wish to get more than a smattering of physiological science. Dr. BRINTON has well performed the duties of editor and translator.

HARMONIES OF PHYSICAL SCIENCE IN RELATION TO THE HIGHER SENTIMENTS; with Observations on the Study of Medical Science, and the Moral and Scientific Relations of Medical Life. By WM. HINDS, M.D. pp. 195. London: 1853.

THIS is a well written little volume, abounding in excellent illustrations of sound principles. We quote the following judicious remarks upon a subject which is now engaging the earnest attention of a large number of our readers.

"GRATUITOUS MEDICAL SERVICES.

"The boon of gratuitous service which our profession with so liberal a hand and under a sense of duty, affords, and has almost from the beginning of its existence afforded to the public, has become converted into so familiar a notion with many, as to blind them to a just sense of our relation. Hence, we are sometimes called upon by public bodies to become gratuitous officers of health, and in various other ways gratuitously to exercise our calling in relation to the general community, and *not to the poor*, without other reward than what may be supposed incidentally or honourably connected with the position and functions; such indirect personal advantage, or distinction, being pointed at as our reward. Now this is a principle we would condemn; and we do it on the highest ground that can be assumed. It is surely far from legitimate, useful, and expedient, to place before the medical body at all times indirect and positive personal rewards for these gratuitous services to the public in general and to the poor. Our profession might say to these public bodies who have occasion to use our exertions and services for legitimate charity, and for the relief of suffering and disease among the poor, that if you thus successfully appeal to our personal advancement, and mere personal interests, as the ground on which we should render those services, you destroy not only our independent and fair claims, but our principle of good. You debase our motives and freeze up our good feelings and our charity. You make us the mere tools of a sordid sense of personal interest, and the slaves of our own selfishness. In fact, the very charities which we wish to exercise, you convert into debasements, because those charities do not deserve the name. You, in fact, convert us to what is little better than a mere hypocrisy, and that is not the character we desire to sustain; nor is it that which is most useful to the community. If then you desire not to lessen our value to the poor, and to society in general—if you would see our principles of charity fostered, preserved,

and elevated—appeal alone to our higher feelings and principles. Show us that our humble services can be usefully employed in supplying the wants of the poor and needy, and the appeal you make to us shall never be made in vain; but we will strive to preserve our principles from debasement, and use our powers to prevent the conversion of our very virtues and charities into instruments for our own deterioration and the impairment of our usefulness." (pp. 177-9.)

PRACTICAL TREATISE ON INFLAMMATION OF THE UTERUS, ITS CERVIX AND APPENDAGES. By JAMES HENRY BENNET, M.D. Third edition. 8vo. pp. 532. London: 1853.

THE past and present editions of this work of Dr. HENRY BENNET have tended in a very high degree to advance the pathology and practice of uterine diseases. This treatise is written with so much ability, enthusiasm, and clinical inspiration, that a great impression in favour of the author's principles of practice is generally left upon those who peruse it with unbiassed minds. We do not mean these remarks to imply that we assent to everything which we find in Dr. Bennet's treatise; on the contrary, we think that in the treatment of inflammation, ulceration, and hypertrophy of the cervix uteri, he does not attach sufficient importance to the curative powers of rest, assisted by variously modified constitutional treatment; and that he insists too much upon leeching, cupping, scarifying, and cauterizing. All of these remedies are valuable in particular circumstances; and we admit that some cases which cannot be cured without their assistance, become with it amenable to treatment. The advantages of local treatment, and the necessity of an accurate diagnosis of uterine diseases, are the great lessons which have been taught by Dr. Bennet's writings during the last twelve years, and they are likewise the lessons which are so well presented to the profession in the volume before us. They require, however, to be accepted with that amount of reservation which we have suggested. As this is a third edition, the work of Dr. Bennet is doubtless familiar to the majority of our readers, and does not therefore require any analysis by us. We shall therefore only remark that this edition is of far higher value than its predecessors, as it contains not only many new chapters, but also the result of the author's recent and enlarged experience upon all the varieties of uterine diseases which he discusses.

CHANGE OF CLIMATE IN DYSPEPTIC, PULMONARY, AND OTHER CHRONIC AFFECTIONS; with an account of the most eligible places of residence for Invalids in Spain, Portugal, Algeria, etc., at different seasons of the year. And an Appendix of the Mineral Springs of the Pyrenees, Vichy, and Aix les Bains. By D. J. T. FRANCIS, M.D. pp. 339. London: 1853.

THE amplitude of the title-page (which we have transcribed in full) gives a tolerable idea of the contents of the work. The information given is considerable in amount, and the materials are skilfully cemented by the judicious observations of the author, who has visited the parts which he describes. We feel, however, when we read such volumes as that now before us, that they have, unless wisely read, a dangerous tendency, as they are apt to lead to the pursuit of that health in foreign climates which might have been found as easily at home, if to be found at all. Travelling in foreign countries, when properly conducted, is a delightful pastime, and often the best means which can be devised for improving the health: but a prolonged residence abroad is another affair; and when mental change is not the main object, we believe that more suitable head-quarters may, in the majority of cases, be selected within our own island than in any of the lauded climes of the south or other more distant lands of hygienic celebrity. The south of Spain is preferred by the author to Italy as a residence for invalids; and in this opinion we cordially concur. We have pretty minutely explored Southern Spain; we have subsequently,

from time to time, sent patients to Seville and to Malaga ; and we are prepared to admit, with Dr. Francis, that,

"When judiciously selected cases of disease are sent to Spain each one to the locality best adapted to its treatment, the climate of that country in its good results will rarely disappoint any reasonable expectation." (p. 6.)

But then we would be quite as willing to allow that the truth of the quotation would not be much lessened by erasing "Spain" in the first line, and substituting for it the words "localities in the United Kingdom". All this we say without disparaging Malaga as an excellent wintering place for the consumptive invalid.

With reference to the hygienic influence of climate, it is important to remember, that that which might, *a priori*, be considered likely to prove beneficial, often turns out hurtful—a strong argument against the rash expatriation of invalids. Guernsey, Bath, Clifton, or Bournemouth, are more accessible, and are often as suitable as Malaga or Madeira. In numerous cases, skilful climate-doctors have sent patients abroad for advantages inferior to those which they might easily have commanded at home ; while others are constantly shifting families from one suburb of London to another in quest of health, only to render them more delicate and more unhealthy.

"Spasmodic asthma," says Dr. Francis, very truly, "is generally benefited in a most signal way by change of air ; but no rules can be laid down for the choice of a locality. Each case of this capricious disease must be considered by itself, and the rule of treatment by climate founded, where it is possible to do so, on the previous experience of the patient." (p. 51.)

This remark, we think, has a much wider range of application than that awarded to it by the author.

There are three fundamental truths connected with change of climate, which are too lightly regarded by physicians ; viz., that, as a general rule, the persons who reach the most advanced years, are those who never change their native air ; that families and individuals very often, when they remove from one locality to another, lose health for a time, but regain it after becoming acclimated ; and that, as a general rule, any change of climate—especially a sudden and great change—often commences a break up of health in elderly persons.

CHEMISTRY OF THE FOUR SEASONS, etc. By THOMAS GRIFFITHS, late Professor of Chemistry in the Medical College of St. Bartholomew's Hospital, etc., etc. London : 1853.

It may be lazy criticism, but unjust neither to author nor reader, to extract from a book under review either an episode, a description of place or character, or a series of paragraphs capable of being disjoined from the text without injuring it. The possible purchaser can thus view the article through his own spectacles, and allow his own palate to pronounce upon it, instead of surrendering his vision, taste, and judgment, to a professional taster. We select for the delectation of our readers the first passages we meet with in this book capable of isolation—passages, moreover, which we cannot but suspect are special pets of our author, who is thus allowed to speak for himself.

"Behold the wondrous phenomena of the four seasons !

"In spring, first verdure clothes the earth, fair flowers adorn its surface ; rippling streams wind throughout the fields ; fragile buds, tender leaves, and sweet blossoms, bedeck the trees ; delicious odours float upon the air ; soft showers descend to fertilise the soil ; the glorious sun shines forth to cherish all nascent forms with its genial warmth ; the gorgeous rainbow spans the heaven to enhance the loveliness of the unfolding scene ; whilst ethereal light and heat augment in power unto the glow of summer.

"Then limpid waters teem with countless forms of life ; luxuriant foliage crests each waving bough, and proffers cool shadow from the scorching sun ; clustering flowers vie in display of beauty and emission of perfume to the dazzling sky ; exuberant productions of smooth meadows and furrowed land bend gracefully to the balmy gale, and ripen speedily for the scythe and sickle ; anon, the sultry noontide heat, the cool night-dew, the

lowering thunder-cloud, and the vivid lightning, herald the advent of autumn.

"It comes, crowned with azure and arrayed in russet robe, wreathed with brilliant flowers, and sparkling with aqueous gems, laden with purple fruit and golden grain ; it pours the abundant produce of the cultivated earth into the wide storehouses of the provident, to reward arduous labours, to realise anxious hopes, to afford generous support in time of need, and having thus fulfilled its beneficial purpose, slowly departs with declining radiance upon its destined course.

"Humid mists appear ; portentous clouds accumulate ; impetuous winds blow ; bright flowers fade, droop, and die ; rustling leaves wither, fall, and decay, whilst glittering hoar frost invests their parent branches ; flowing waters are arrested in their rapid course, and fettered with hard transparent ice ; fierce tempests rush throughout the darkened air, and spotless snow flakes form the winter mantle of the earth."

Any commendation of ours would, after this extract rightly expose us to the charges of that wasteful and ridiculous excess, which our great poet lays at the door of those who dare "to throw a perfume on the violet". We therefore, content ourselves with earnestly recommending this portable volume to all who are capable of appreciating the beauties of a style, seldom met with since the days of Della Crusca. Some men are said, oddly enough, to live before their time ; if so, the converse certainly happens, for it requires no stretch of the imagination to listen to the little scream of delight with which Rosa Matilda would have welcomed this scientific writer, or how quickly she, with her attendant nymphs and swains, would have been deep in *The Chemistry of the Four Seasons*.

The book contains numerous religious reflections, some of which are not always seasonably introduced. It is, moreover, furnished with an appendix of the names of the discoverers, etc., of the principal facts embodied in the work ; a list in which the discoveries of the four chemists Berzelius, Graham, Wöhler, and Wollaston, are comprised in as many lines, while those of the author occupy half a page.

EXAMINATION OF DRUGS, MEDICINES, CHEMICALS, ETC., as to their Purity and Adulterations. By C. H. PEIRCE, M.D., etc. Philadelphia : 1853.

The adulteration of medicines imported by the United States was a short time since made the subject of special investigation by a most competent committee, whose reports, as they reached this country, we read with the pleasure arising from the spectacle of knavery searchingly exposed, and rascality detected by the judgment, skill, and science of honest and able men. The result of this examination was that the adulteration was found to be the rule, purity the exception, with the imported preparations ; an evil for which, when ascertained, Congress was not slow in providing a remedy, in the appointment of examiners at the principal ports of the Confederation,—an act which Dr. PEIRCE states "has excited a most beneficial influence, not only by causing the rejection of such spurious medicines, but by preventing the importation of them from foreign countries." We would that this crying evil of the sale of spurious, adulterated, or effete medicines could be "put down" in this country, where it prevails to a fearful extent, to the injury of hosts of people, attended even with death to many, and to the constant vexation, perplexity, and discredit of the physician.

We read this book with a prejudice against it, from the identity of its plan and treatment with that of the *Handbook of Chemical Analysis*, published by Dr. Normandy in 1850, and the absence of any tribute in the preface to the labours of Normandy, of which Dr. Peirce has largely availed himself, and of Mitchell in England, or of Guibourt, Garnier, Hard, Busby, Boutron, and Charland, whose works have directly or indirectly contributed to this compilation. This undervaluation of the labours of his predecessors in this department of chemistry, especially in respect to Dr. Normandy, is deserving of censure ; yet we are desirous of adding that the book is a mere transcript of the *Handbook*, and that the names and directions are concisely and generally copied, so that the work is likely to be serviceable to those who

of drugs in the ports of the United States, for whose use we presume it was compiled.

For the use of our own countrymen we cannot recommend it; not because the book itself is a bad book, but merely because in the British and continental authors we have named, we have better books on this subject within our reach than this by Dr. Peirce. Of these two books, Peirce's *Examination, etc.*, and Normandy's *Handbook*, similar in subject, in plan, and in treatment, we greatly prefer the latter, and should recommend it to our readers who may be desirous of determining for themselves the purity of the drugs supplied to them.

EVENING THOUGHTS. By a Physician. 12mo. pp. 143. Second Edition. London: 1852.

This volume contains fifty-four fragmentary pieces—the contemplations of an accomplished, genial, and pious mind. Like Coleridge's *Aids to Reflection*, they open up rich veins of profitable musing; and, unlike the majority of emanations from the modern press, they invite to reperusal.

THE SEA-WEED COLLECTOR'S GUIDE: containing Plain Instructions for Collecting and Preserving, and a List of all the known Species and Localities in Great Britain. By J. Cocks, M.D. 12mo. pp. 87. London: 1853.

THIS little work admirably supplies a want which has been long felt and acknowledged by algologists.

PERISCOPIC REVIEW.

PRACTICE OF MEDICINE AND PATHOLOGY.

GLANDERS IN THE HUMAN SUBJECT: TREATMENT BY LARGE DOSES OF SESQUICARBONATE OF AMMONIA.

Several cases of glanders occurring in the human subject have from time to time been recorded in the various medical periodicals. We subjoin an abstract of the histories of such of those as have been related from 1849 to the present time. We wish to call particular attention to Dr. Mackenzie's treatment by large doses of sesquicarbonate of ammonia.

The *Revue Médicale* for January 1850 quotes from the *Journal de Médecine de Bordeaux* for October 1849, the following case, related by Dr. H. GINTRAC.

CASE I. The patient was brought into hospital in a state of febrile delirium, apparently referrible to cerebral irritation or inflammation. On inquiry, nothing could be elicited but that the man was a waggoner, and had complained for a week of fever and *malaise*, and of wandering pains in the limbs; and that, since the preceding day, he had had violent agitation, convulsions, and delirium. A severe pain which he felt in the left shoulder was believed to be rheumatic; but, after death, a collection of pus was found in the left scapulo-humeral articulation. It was not till the fifth day that a rigor appeared: on the next day, the nose presented considerable swelling, with purulent and fetid exudation; and slightly prominent red patches were seen on the limbs. It was then discovered that the man had for some time attended to a glandered horse.

After death, the usual appearances of glanders were found.

The following case is related by M. HAIRION, in the *Archives de la Médecine Belge* for 1849; and is quoted in the *Gazette Médicale de Paris* for June 8th, 1850.

CASE II. D., a labourer, aged 23, usually strong and of good health, had to attend to three glandered horses during six months of 1845 and 1846. He lay in a stable occupied by these animals. In the course of this winter, he felt a violent pain below the right breast, and was obliged to keep his bed for some days. Two or three months later, towards May, he complained of catarrh, which impeded respiration, and caused the escape from the nostrils of a thick inodorous matter, occasionally pretty abundant. This gradually diminished; but the patient did not become quite free from it.

In the early part of January 1847, D. entered a regiment of *chasseurs*. Towards the middle of March, there appeared on

the left arm, a little below the insertion of the deltoid, a small indolent tumour, of the size of a walnut, without change in the colour of the skin. The tumour increased slowly; but the patient did not apply for medical aid until he found himself unable to work. The abscess opened spontaneously, and gave exit to a large quantity of pus: it did not heal under three months. During his stay in hospital, the catarrh increased. At the same time, a slightly painful hardness was felt towards the lachrymal sac, on the left side. The patient left the hospital on December 11th, 1847, but was readmitted a fortnight afterwards. The tumour near the eye enlarged to the size of a pigeon's egg, then discharged a tolerably large quantity of pus. It cicatrised incompletely, leaving a fistulous opening. At the same time, a similar tumour appeared at the internal angle of the right eye: it went through the same course. There was now also pain in the nasal cavity, with an escape of inodorous pus, sometimes very abundant. The patient was treated with hydriodate of potash, and a liberal tonic diet.

D. left the hospital after he had been in it about a year and some days. He was then tolerably stout, and looked healthy; but he soon began to grow thin, and became weaker daily; the discharge from the nostrils became fetid. The patient extracted some portions of bone and fragments of mucous membrane from his nose. He was admitted into the hospital at Louvain, on January 27th, 1849, in the following condition.

He was greatly emaciated: the skin was yellowish. At the inner angle of each eye, in the centre of the cicatrices to which reference has been made, there was a small fistulous opening, from which sero-purulent matter escaped. The cicatrices were adherent to the bones, and completely impeded the lachrymal ducts. The patient felt a sensation of cold in the nose. The whole of the septum narium was destroyed, except the lower part. The inferior and middle turbinated bones had entirely disappeared. The mucous membrane of the whole nasal cavity was red, fungous, and livid, covered at some points with brownish crusts, and secreting a very fetid pus. The arch of the palate was the seat of a deep oblong ulcer: its edges were indented, and its base was greyish: the corresponding osseous surface was in a carious condition. Posteriorly to this, there was the cicatrix of an ulcer which had previously existed on the palate. The appetite was bad, digestion was difficult, and there was occasional diarrhoea. The pulse was small, feeble, 100: there was fever in the evening. Nothing important could be discovered in percussion or auscultation.

M. Hairion, thinking the case one of syphilis, treated it accordingly, but without any result except that of rapidly weakening the patient. A week after the admission of D., M. Hairion learned that he had had the care of glandered horses. Tonics were then prescribed; but they could not be borne. The patient grew worse daily, and died on March 9th.

No examination of the body was made.

The following case is related by Dr. BALLARD, in the *Lancet* for January 12th, 1851.

CASE III. J. G., aged 28, a strongly built man, who had always enjoyed good health, had been engaged for fourteen months in attending to a number of glandered horses. When attending to the horses, he generally, but not always, wore gloves. He had often been present at the *post mortem* examinations, but had never assisted in any. Some days after Dr. Ballard first saw him (which was on August 9th), he discovered, behind the right arm, a bloody crust, which the patient admitted to have been a pimple which he had scratched. He had, for three months before the attack, complained of dyspeptic symptoms; and there had been some unnatural puffiness about the forehead, eyelids, and upper part of the nose.

On July 21st, there was pain in the right hypochondrium, and in the forehead, and a tender swelling, apparently muscular, above the left shoulder. The swelling subsequently disappeared.

On August 3rd, a circumscribed swelling was noticed about an inch and a half above the right external angular process of the frontal bone.

On August 6th, pustules were seen on the last named swelling, and in its neighbourhood. The next day, they had become confluent, and had burst, giving place to ulceration; simultaneously with which, the integument higher on the forehead became purple, and was covered with blebs.

On August 9th, when Dr. Ballard first saw the patient, the ulcerations left by the bursting of the pustules presented a surface about as large as a crown-piece, very irregular in outline, and worm-eaten in appearance, crossed by ridges of sloughing tissue: there was no bad odour. There were also,

towards the middle line of the forehead, flatish pustules, about a line and a half in diameter, with a tendency to form in circular groups or in rings. More to the left, there was erythematous redness, with swelling, pitting slightly on pressure, and terminating on the left side of the forehead by a circumscribed border, giving it the appearance of erythema nodosum. The right eyelid was swollen, and the eye was closed by the gumming of the discharge. There was no affection of the throat or mouth; and the nose was free from discharge, stuffing, or fulness. There was a red circumscribed swelling over the right external malleolus, and another on the external border of the foot: they were not painful, but were hot to the touch, and tender. There was remarkable tremulousness of manner; the patient felt weak, but could sit up in bed; there had been some delirium at night; the skin was hot and moist; the pulse was 104, strong and firm: there was some thirst and clamminess of the mouth, and the tongue looked congested, with a dirty white fur at the back part. During the fortnight preceding the outbreak of the eruption, there had been frequent very sour sweats; the patient had felt confused in his head, and suffered from much languor and debility. He was ordered to take gr. ij of opium at night, and a colchicum mixture during the day.

August 11th. The patient passed a tolerable night, during which there were abundant sour perspirations. His wife stated that she had in the morning wiped a trifling discharge, tinged with blood, from his nostrils. He occasionally hawked up some pearly mucus, with milk-white streaks.

August 10th. He was delirious in the morning. Both eyes were closed by the swelling of the lids; the pustules in the forehead had formed ulcers; and there was a fresh group on the root of the nose. There was general swelling of the right ankle and foot, besides the swellings already described. Some bloody discharge was again stated to have been wiped from the nose. The mouth was drier, and the tongue browner; the pulse more atonic. The opium and the colchicum mixture were continued; and dilute solution of chloride of lime was added to the poultices with which his forehead was dressed.

August 13th. Some pustules had appeared on the thighs and arms; and there was a trifling discharge from the right nostril.

August 14th. The pustulation and ulceration went on increasing. There were low delirium, sordes on the teeth, and other symptoms of a low condition.

August 15th. There were more depression and tremor, and constant muttering delirium. The forehead presented, over its whole surface, a slough mixed with irregular ulceration. There was a large patch of phlyzaceous pustules, of the size of a half-crown piece, on the lower lid of the right eye; the whole upper part of the face and nose was greatly swollen; and a purulent discharge issued from between the lids of the right eye. There were more pustules on the limbs. There was noisy expiration through the nose, and the discharge from both nostrils was abundant, thick, and rather sanguinolent, drying upon the upper lip. There was swelling of the right wrist metacarpus. There was evident difficulty of swallowing. The patient was not violent during the night, but sweated abundantly, the sweat not being sour: his aspect was that of a man dying of typhus; he lay low in bed, on his back; his attention could with difficulty be roused; there were abundant sudamina on the abdomen; he passed his urine under him.

August 16th. The patient became unconscious at two o'clock in the morning, and died at 10 p.m.

M. GRASLEPOIS relates the following case in the *Journal de Médecine et de Chirurgie Pratiques* for August 1851. An abstract appeared in the *Monthly Journal of Medical Science* for October 1851.

CASE IV. On June 12th, 1851, a veterinary surgeon in the commune of Vars, aged 64, of bilio-nervous temperament, generally healthy, but who had for some years suffered from slight epiphora, was called to attend a glandered mare. While he was examining the nostrils of the animal, it sneezed, and threw into his face a jet of yellowish green mucus. He immediately endeavoured to remove it, by washing with cold water; and returned home.

On June 17th, the patient (who was travelling) felt acute smarting pain at the internal angle of the right eye, followed by tumefaction and redness. These symptoms increased up to June 20th, when M. Graslepois was consulted.

There was now considerable swelling and vivid redness of the eyelids, and of the ocular and palpebral conjunctiva, complete immobility of the iris, loss of vision in the right eye, intense headache, a full, sharp, and strong, but regular pulse, a hot and

dry skin, and excessive thirst. Believing the symptoms to be those of an ordinary inflammatory attack, he had the patient bled to 3viij, and ordered linseed poultices, etc. In the evening, there was general prostration, a more feeble and excited pulse, lividity of the eyelids and conjunctiva, a pustular swelling below the greater angle of the eye, oedema of the cheeks and of the sides of the neck, incipient delirium, spasmodic agitation of the limbs, pain in the large joints, with swelling and livid discoloration, abundant discharge of a yellowish green matter from the right nostril, and, shortly afterwards, from the sore on the eyelids. A blister was applied to the nape of the neck.

Next day, M. Graslepois, in consultation with another practitioner, attributed the symptoms to the bite of an insect. A tonic mixture, a lotion, and blisters to the legs, were ordered. The blistered surface on the neck was livid, and the pus unhealthy. In the evening, a pustule had appeared on the right wrist and back of the right hand, surrounded with diffused livid redness. There was doughiness of the neighbouring cellular tissue. The delirium was more marked; and all the symptoms of general infection were present. Engorgement of the glands and lymphatic ganglia are not mentioned.

The disease continued to make progress; the respiration became embarrassed; deglutition was impossible; and the patient died.

No examination of the body is recorded.

In the *London Journal of Medicine* for September 1851, Dr. F. W. MACKENZIE relates a case of acute glanders, in which the patient recovered.

CASE V. W. W., a horsekeeper, aged 58, was admitted into the Paddington Infirmary, late in the evening of the 19th July. He was seen by Dr. Mackenzie the next day, and appeared very dangerously ill. His face generally was swollen and suffused, but more especially in the submaxillary region. A large quantity of saliva was pouring from his mouth, his breath was extremely fetid and sickening, his gums were swollen, and his teeth loose—some indeed were merely hanging from the gums. The tongue was much enlarged, and could not be protruded beyond the margin of the teeth, and it was forced upwards against the roof of the mouth by the swelling of the salivary glands below; the throat was constricted, and consequently both breathing and swallowing were difficult. His nostrils were filled with a thick glutinous secretion of an offensive odour, which was with difficulty dislodged. The patient had been very restless all night, had been constantly throwing his arms about, was alternately chilly and hot, and at times sweated profusely; he had a quick pulse, and was in a state of extreme prostration. Looking to the profuse salivation, the condition of the salivary glands, the extreme fetor of the breath, and the state of the gums and teeth, the first impression was that he had been severely salivated with mercury. It appeared, however, that he had not taken a particle of this medicine for some time, and his general symptoms were, moreover, inconsistent with this view. He had begun attending to some glandered horses on June 18th; and, in grooming them, frequently had the secretions blown on his face; and the stench of the stable was very great. In a few days, he began to feel feverish and ill, with loss of appetite, and disorder of the stomach.

On July 13th, while cleaning the horses, he felt completely overpowered by the stench; and he became so ill, that he was obliged to leave the stable abruptly. He was now seized with severe headache and giddiness, and swelling of the face. Lachrymation and profuse salivation soon followed. He said that half a pint of fluid ran from his mouth in the course of an hour; his teeth became loose, and the gums painful and tumid. His tongue began to swell, his throat felt constricted, and his nostrils became filled with a thick yellow, fetid, glutinous secretion. He had frequent rigors, succeeded by heats and cold sweats, and he felt very low and weak. He was now obliged to give up his work, and was advised to take some gin, which, together with beer, he drank from time to time; but his stomach was so irritable that very little would stay upon it.

When admitted into the Paddington Infirmary, he was in a very exhausted state; he breathed with difficulty, and could scarcely swallow some wine which was given him. The fetor from his mouth was most intolerable; he was restless, passed the night without any sleep, and was observed to throw his arms continually about.

On the following day, his breathing was more difficult, and the swelling of his face had increased; this was most marked under the lower jaw, where it formed an enormous tumour. There was a profuse discharge of saliva running from his mouth; the tongue was tumid, and its surface was covered with

white, moist fur; the gums were soft and swollen, and his teeth loose. On passing the finger under the tongue, a large elastic tumour was felt on each side of the frænum linguae, apparently consisting of the enlarged sublingual and submaxillary glands, and the distended ducts of the latter. Dr. Mackenzie made a free incision in each of these; and a great quantity of clear glairy mucus poured out, which gave the patient much relief. Dr. Mackenzie was unable to examine the throat, on account of the general swelling of the parts; but from the character of the breathing and the difficulty of swallowing, it was evidently swollen, and the isthmus faucium contracted. He could not, however, see any erosion, ulceration, or pustules. The nostrils were filled with a viscid, yellow, opaque secretion, which was with difficulty dislodged, on account of its tenacity. The conjunctivæ were injected, and the eyes watered profusely. The patient complained of severe headache, which was greatest over the eyes and frontal sinuses, but at times it was felt over the greater part of the head. He was very sick, could not retain food upon his stomach, and was very restless and uneasy. He stated that he had not slept for a week. He was alternately chilly and hot, and, at times, broke out into cold sweats. His pulse was quick and weak, and he complained of great lassitude. He had no rheumatic pains, or any perceptible eruption on the skin or mucous membrane; the blister which had been applied had risen, and had a greenish, sloughy, unhealthy appearance. His bowels had twice acted during the morning, and he had passed water freely.

He was directed to take immediately an emetic, consisting of half a drachm of ipecacuanha; and, as soon as vomiting had ceased, to take five grains of the sesquicarbonate of ammonia in water every hour, using as little water as possible; to use frequently a gargle of the chloride of lime, and to have wine and such nourishment as he could swallow given freely, and to take at night an opiate, consisting of twenty drops of the tincture.

July 21st. On visiting him in the afternoon, his appearance was in every respect improved; his face was less swollen, as was also the tongue and salivary glands. He spoke, breathed, and swallowed better. His tongue was reduced in size; he had slept comfortably during the night, and taken nourishment, such as beef-tea, freely. His pulse had fallen to 80; the skin was cool, and he had experienced no rigors during the day. He said that the emetic occasioned copious vomiting of green unhealthy matter; and that as soon as this had taken place, he felt relieved, and as if a load had been taken off him. He subsequently took the ammonia as directed. He was ordered to continue this, and to take five grains of blue pill at bedtime, as the tongue was still rather white.

He continued to improve under this treatment. The ammonia was discontinued on July 25th, and he then took nourishing diet, with a pint of porter daily. He was discharged cured on July 28th.

The following case is related by Dr. TESSIER, of Lyons, in the *Union Médicale* for July 22nd, 1852. An abstract was given in the *London Journal of Medicine* for October 1852.

CASE VI. On June 8th, 1852, a woman, named A. J., aged 47, was brought to the Hôtel Dieu at Lyons. She was married and worked in silk. Her lodging and food were healthy and sufficient. She had led a very sedentary life. It appeared that she had not been in contact with horses, had had no transactions with coachmen, grooms, or cavalry soldiers, and had touched no object which could have been charged with the virus of glanders. There was a butcher's shop in her house, but not a slaughter-house; good meat alone was sold there. In 1849, she had syphilis.

On May 30th, being exposed to a draught of air while her body was covered with sweat, she experienced a feeling of intense chill, which lasted four days, and was accompanied with debility, headache, anorexia, and pains in the joints. On the fourth day, when reaction was established, there appeared, on the middle of the front of the right leg, a white pustule, surrounded by a red areola.

On the fifth day, the dorsal surface of each foot was covered with oedematous erysipelas; and on the aspect of extension of the four limbs, there suddenly appeared, with or without discoloration of the skin, more or less painful hard nodosities. On the succeeding days, the symptoms continued; an abscess formed under the pustule in the right leg, and was opened on the day before the admission of the patient into hospital.

On admission, her countenance was anxious; the skin hot; the pulse quick; the tongue whitish and dry; she had headache, and general pain; there was much thirst; she answered questions with some difficulty. She was much agitated; and complained

of not being able to sleep, or rather that her sleep was broken by painful startings. The legs were oedematous, and presented diffused erythematous patches on their anterior part, and on the dorsal surface of the feet. She could not bear the least pressure on the great and second toes of the left foot. Eight or ten tumours or nodosities, some tender, with or without inflammation of the skin, others fluctuating, and evidently formed by abscesses, existed on both upper and lower limbs. A sanious pus escaped from the abscess in the leg; two pustules resembling æthyma were observed, one on the styloid process of the right ulna, and the other on the summit of an abscess on the thigh. She was ordered to have diaphoretic ptisan, a calmative mixture, ointment, and a poultice to the abscess.

Up to June 14th, the symptoms went on increasing; and she was ordered to take tincture of aconite, and to have the sores dressed with powder of cinchona and charcoal. Under this treatment, gangrene of the leg, which had set in, was arrested. At this time, there appeared two new pustules, like those of variola at the stage of suppuration, and an abscess with violet coloured skin, over the left malar bone. Up to this time, Dr. Tessier had treated the case as one of fever, with a tendency to the formation of abscesses and to erysipelas; but the appearance of the varioloid pustules on the face led him to suspect that the case had some resemblance to one of glanders. As, however, there was as yet no purulent discharge from the nostrils, he did not arrive at any conclusion.

On June 16 and 17, the varioloid pustules increased in number. The face expressed stupor, the tongue was dry, the abdomen in a state of meteorismus. M. Lecoq, director of the Veterinary School, examined the patient, but could not decide whether she had glanders. The abscesses and pustules increased in number; there was extreme prostration, with subsultus tendinum, and some petechiæ on the thorax.

On June 20, there appeared erysipelas on the face, below the internal angle of the eyebrows: it spread rapidly, and on the next day assumed a blackish tint, and became covered with phlyctenæ. The pustules and abscesses became more and more numerous. The pulse was 130; the tongue appeared as if roasted, and some small blackish crusts were observed in the interior of the nares, but there was no discharge.

On June 21st, diarrhœa set in, and phlyctenæ appeared on some of the abscesses on the limbs. The patient died in the morning of the 22nd.

EXAMINATION OF THE BODY, twenty-four hours after death. There were six or seven bullæ on the limbs, containing a sero-purulent liquid, and two gangrenous phlyctenæ, one at the root of the nose, the other on an abscess in the thigh. There were twenty-nine opaque pustules, resembling those of small-pox at the period of suppuration, but without the central depression. Traces of erysipelas were seen only in the face. Where it had been present on the feet and hands, thick pus was found beneath the skin. There were twenty-seven abscesses, two of which were gangrenous. Some were subcutaneous: others were deeper seated among the muscles; while some were within the joints. Pus was found in both knees and elbows, and in some of the joints of the toes. The pulse was generally thick, unhealthy, and mixed with grumous clots. In some of the abscesses it was sanious.

The brain was healthy; there was slight arborescent injection of the arachnoid. The sinuses of the dura mater were filled with dark blood.

In the nasal fossæ, the mucous membrane was thick, softened, of a very deep red, and was easily detached from the bones. It was infiltrated with a sanguinolent serosity through nearly its whole extent. At some points, it presented granular erosions, infiltrated with pus (an essential character of glanders). The turbinate bones were of a blackish aspect: they were filled with sanguinolent and purulent mucosity; so that, if the patient had lived two or three days longer, there would have been a discharge from the nostrils. The mucous membrane of the fauces presented the same appearances as the pituitary membrane, but in a less degree. There was no abscess in the lungs; but they were infiltrated with dark blood, and the left lung presented, especially posteriorly, marked lobular engorgement. The heart was healthy; as were also the liver, spleen, pancreas, and kidneys. The sexual organs presented no trace of syphilis.

In the stomach, there was an ecchymotic patch of the size of a five-franc piece; and the mucous membrane here was softened. Throughout the intestines, there were only some red arborescent patches of cadaveric injection. Peyer's and Brunner's glands were healthy. The absence of pathological changes in the intestines is one of the most important points in the anatomical

history of glanders. The lymphatic glands were not visibly enlarged.

The following case, which occurred in the Hôpital de la Pitié, under M. VALLÉIX, is related in the *Gazette des Hôpitaux* for 14th December, 1892.

CASE VII. A carpenter, aged 25, was admitted on November 25th, 1852. Up to May 1852, he had enjoyed good health; he then had headache, *courbature*, and dyspepsia; which disappeared on resting a few days.

On October 12th, he was seized with great weakness, fever, insomnia, and bilious vomiting. He became an inmate of the Hôtel Dieu, for a fortnight, and left much improved.

On November 20th, he felt very ill; and on the 25th, was admitted into the hospital. On being questioned, he at first denied having entered a stable, or having had any communication with horses or persons engaged in their care. It was, however, learned that he had lain in a room over a stable, and that he had frequent communication with a carter in the house where he dwelt. Six months before his last attack, he had heard that one of the horses had glanders; but he did not believe it.

On November 26th, the following was his condition. The face was red and anxious; the nose was swollen and tender. From time to time a peculiar expiratory movement was observed, which caused a sanious aspect of peculiar appearance to escape from the nostrils. The nasal fossa were of a blackish colour. The tongue was white and soft. The base of the tongue was much swollen; and as often as attempts were made to depress it, convulsive movements were excited, giving rise to the expulsion of abundant viscid mucus. The uvula was red and much thickened; and these conditions apparently extended to the neighbouring parts. Deglutition was difficult. The appetite was lost; and there was pretty severe thirst. There was nothing remarkable in the abdomen, except some pain in the epigastrium and right hypochondrium. No urine had been passed for twenty-four hours; the bladder was empty. The respiration was noisy, but regular, from twenty-four to twenty-eight in a minute. The stroke-sound of the chest was healthy; and no abnormal breath-sounds could be perceived. There was no heart-disease. The general symptoms indicated high febrile reaction.

At the most dependent part of the lower eyelid, near the cheek, there was an irregular projecting white pustule, resting on a tumefied base; the light rose colour and the oedematous swelling of which were gradually lost towards the face and the temple. A second similar pustule was present on the upper eyelid; and a third, larger and more irregular, was situated on the ulnar side of the left arm.

The patient's intellect was affected; he replied slowly to questions put to him; he seemed to recollect events of a remote date better than those which were more recent. He was in a state of prostration, from which he could momentarily recover.

He was bled to a little more than six ounces; and a pill of opium, and fifteen grains of sulphate of quinine, were prescribed. In the evening, the pain in the epigastrium and hypochondrium, and the debility, had increased.

On November 27th, he was worse. In the course of the day, about 4 P.M., he was suddenly seized with epilepsy. No cry was heard by those around him; he had violent contraction and flexion of the arm and thumb; a sanguinolent froth escaped from the mouth. Sinapisms were applied. The convulsions continued to recur at intervals, until 5 A.M. next day, when he died.

EXAMINATION OF THE BODY, November 29th. There was no putrefaction. Over the whole extent of the upper surface of the nasal fossae, the membrane was soft and puffy, and of a bluish colour. It was covered with anfractuous depressions. Its consistence was much altered; it being in some parts softened, and of a greyish tint. On maceration, ulceration was not detected; but a number of small points, of about the size of a pin's head, were discovered, in which the Schneiderian membrane appeared as if punched out; these were evidently commencing ulcerations. The mucous membrane of the nasal fossae was red, soft, and puffy, and covered with a very adherent ropy, greyish mucus. The mucous membrane of the pharynx was in the same condition. The other organs, especially the liver, were much congested.

The following case is related by Dr. JAMES WALLACE, of Glasgow, in the *Medical Times and Gazette* for December 18th, 1852.

CASE VIII. April 16th, 1852. J. M., a farmer, about 40 years of age, of rather intemperate habits, of a spare figure, and, although he had always enjoyed good health, apparently of a weak

constitution, was seized ten days previously with rigor, followed by pyrexia and general uneasiness. Three days afterwards, he had swelling, pain, and redness of the middle of the outer side of the left thigh, accompanied in three days by a similar condition of the posterior portion of the right. When seen by Dr. Wallace, there was a subcutaneous abscess in the former situation, and nearly the whole of the latter was red, swollen, tense, and pained. The patient had urgent thirst, and complained of pain in the right shoulder; the skin was hot and dry; the tongue white but moist; the bowels were regular, though, at the commencement of his illness, rather loose; the pulse was 92, soft. The abscess had been opened, and exit had been given to about one-twelfth of an ounce of sanio-purulent matter; and a free incision had been made through the skin and fascia of the posterior portion of the right thigh.

Linseed meal poultices were applied; and a mixture, containing nitrate of potash, tartar emetic, and compound tincture of camphor, was given every three hours.

April 17th. He had slept well, but complained much of pain on the dorsum of the right foot, which was swollen and red in streaks. Two pustules had appeared, one on the inner side of the left thigh, and the other on the back; they were about the sixth of an inch in diameter, convex on the surface, and very hard; the surrounding integument, for the space of an inch and a half, had an erysipelatous blush, which gradually faded towards the circumference.

April 19th. He complained much of pain in the foot, which was more swollen and red; he had pain in right wrist and elbow, but none in the shoulder. The redness and swelling had left the right thigh, and the discharge from the abscess on the left was very copious and thin. A considerable number of pustules, like those above mentioned, had appeared on the extremities and trunk, and one also over each malar eminence. The tongue was rather dry; the thirst urgent; the skin hot and dry; the bowels open; pulse 100, soft. Ten grains of Dover's powder were given at night. Beef-tea was ordered to be used as drink.

April 20th. The pain, redness, and swelling in the lower limbs were abating; but the swelling and redness surrounding the pustules were spreading, giving the face an appearance of erysipelas. Dr. Wallace now prescribed twenty minims of tincture of sesquichloride of iron, to be taken every two hours; and some muriate of morphia at night.

April 21st. The development of pustules had continued, and their areolae were becoming livid; a few had burst, and were discharging unhealthy sero-purulent matter. The glands in the groin were much enlarged; the urine deposited an abundance of ammoniaco-magnesian phosphates. The tincture of sesquichloride of iron was omitted, and morphia was given. On this and the preceding day, whiskey was ordered.

April 22nd. The patient's breathing became hurried; rhonchi were audible over both lungs; and on the next day he died.

No examination of the body is recorded.

A case is related by Dr. MILTENBERGER, in the *Gazette Médicale* for January 22nd, 1853. It was observed by him in Algeria in 1847.

CASE IX. On October 5th, 1847, *Morand, a soldier in the line*, who had been ill four days, was received into the military hospital of Mustapha, with the following symptoms: lassitude, fever, difficulty of respiration, cough, mucous and subcrepitant rhonchi, and pains in the left arm and knee joint, without swelling or redness.

October 6th and 7th. He was weaker, and had pain in both legs.

October 8th. There was erysipelatous redness and swelling of the right side of the face. Pain was felt in other parts of the limbs; there was redness and slight swelling of the right knee-joint, and of the middle and external part of the left arm.

October 9th. The erysipelas had extended nearly over the whole face.

October 10th. Small acuminate pustules appeared on the limbs.

October 11th. The patient expectorated some gray sputa, without coughing; the cough, which was at first present, had disappeared; the orifice of the nasal fossae was plugged with dry mucus; the nasal mucous membrane was slightly tumefied.

October 13th. The pustules were increased, and resembled those of small-pox. They were twice in number, and were principally over the upper limbs. The patient continued to have swelling and fluctuation of the left arm.

October 14th. The patient was delirious, and died on the following day he died.

EXAMINATION OF THE BODY. There was an abscess under the skin in the left arm; and so many in the muscular tissues, that they were opened by every random incision. The pus was scanty and reddish: it appeared healthy in the right knee and hip-joint. The mucous membrane of the nasal fossæ was of a deep red colour, and was covered with thick mucus, like the sputa which had been expectorated during life, and which were, in fact, mucus from the nasal fossæ, which had fallen into the fauces while the patient lay on his back. The lungs were hard and friable; there was a small purulent collection in the right lung; nothing of note was found on their surface. When the lung was removed, a tumour of the size of a hen's egg was found under the left pleura, at the posterior and inferior part; it contained creamy pus, and communicated with a host of small purulent collections in the muscles of the back, which indeed appeared infiltrated with pus. The last three cervical vertebrae were softened, and pus could be pressed from them.

Dr. Miltenberger made most careful inquiries to ascertain whether the man had come into contact with a glandered horse; but neither questions directly addressed to the patient, nor inquiries of those who were habitually about him, afforded any information. He thinks the case worthy of being recorded along with that of M. Tessier, although he is not satisfied in his own mind that it did not arise from contagion.

In the *London Journal of Medicine* for September 1852, Dr. MACKENZIE gives an account of a case of farcy successfully treated with the sesquicarbonate of ammonia.

CASE X. C. K., a stableman, aged 47, of temperate and regular habits, was admitted into the Paddington Infirmary on the 24th October 1851, suffering from extensive gangrenous inflammation of the left foot. It was extremely swollen, was of a dark livid colour, and very painful and hot; the pain was aggravated by the slightest touch. At the outer ankle, extensive sloughing and vesication had taken place, attended with an offensive sanious discharge. The patient had for some days previously suffered from frequent rigors, and at the time of his admission was labouring under a low typhoid form of fever, was at times delirious, complained much of nausea and sickness, and had not slept for many days or nights. His tongue was coated, his pulse feeble, and there were numerous pustules on his face, neck, and shoulders.

The case was considered to be one of gangrenous erysipelas, attended with much constitutional prostration. He was ordered immediately an emetic of ipecacuanha; after vomiting had taken place, three alterative doses of blue pill, at intervals of four hours between each; and the sesquicarbonate of ammonia, in five-grain doses, every two hours, as concentrated as he could swallow it, and to be supplied frequently with cordials and light nutriment. The foot was kept elevated, and covered with warm bread poultices, saturated with carrot-juice. This treatment was continued for five days, with very satisfactory results. The general condition of the patient had much improved; the prostration had lessened, and he felt altogether better. It had been necessary, however, to give him opiates at bed-time, on account of his restlessness and inability to sleep.

On the fifth day after admission, two dusky patches of inflammation appeared, the one on the inside of the knee, the other a little below it; and on each of these patches a small circumscribed tumour arose, about the size of a walnut. These were painful and tender, and in the course of a day or two suppurated. The character of these tumours led to further inquiries, and the information obtained tended to connect the disease with infection received from a horse. The patient had nearly all his life been engaged in stables, and accustomed to the care of horses; about three months previously to his admission, he had given a ball to a horse, which had a profuse, unhealthy discharge from the nostrils, of a thick, yellow, tenacious character. In giving the ball, the little finger of the patient's right hand was scratched and abraded by the teeth of the horse; and, on withdrawing it, the discharge from the nostrils fell upon this abrasion. The same night the finger became extremely painful and swollen; and, shortly afterwards, the swelling extended to the whole of the arm, which became also very painful. On the following day, he applied at St. George's Hospital, where three incisions, etc., were made in the affected parts, and, by dint of these and other appropriate measures, the severity of the local affection was subdued. Three weeks after the accident, the left foot was attacked with inflammation of a dark purplish colour, which, after subsiding, in the course of two or three days returned, and continued to do so at intervals. Dr. Mackenzie was led to suspect that the disease of the foot and leg was connected with the morbid secretion which had

been received from the horse; and a patient in the ward, who was well acquainted with the phenomena of farcy and glanders in the horse, examined carefully the swellings about the knee, and remarked, that they had very much the character of "farcy buds".

From this time, small circumscribed tumours or swellings of the same description began to appear upon the dorsum of the affected foot; at first they were hard and tubercular, and about the size of a pea; but, in the course of a day or two, they became as large as a walnut, then suppurated, and discharged their contents into the subcutaneous cellular tissue of the foot, whence they formed a passage to the ulceration around the ankle, and there escaped. Swellings, or rather abscesses, of this description continued to form, in succession, upon the foot; so that, in the course of a month, as many as fourteen had appeared. At first they had the character of small tubercles, which softened, and became abscesses; but, after a time, their contents became more and more serous, and at last consisted of a small quantity of watery fluid only.

Ammonia was given, in a concentrated form, every two hours; opiates and alteratives were occasionally given at bed-time, and throughout the patient was kept up by a liberal allowance of wine, cordials, and nourishing food. These measures were urgently required, as the amount of sphacelation and sloughing on the foot during this period, as also the constitutional prostration, were very great. At the end of the month, however, matters had greatly improved; the febrile symptoms had lessened, as well as the prostration; the appetite had returned, the tongue was clean, and the patient slept well at night; the sloughing of the foot had also ceased, and the ulceration left by it had assumed a healthy character; the disposition to the formation of abscesses, or "buds", on the dorsum, however, still continued, and, to meet this, the liquor arsenicalis, in five minim doses, three times a day, was substituted for the sesquicarbonate of ammonia. In the course of a week from this alteration in the treatment, the disposition to the formation of these abscesses ceased, the ulceration of the foot continued to heal favourably, and the patient's recovery was steady and satisfactory from this date. The foot, however, remained for some time cedematous and tender, after all other morbid appearances had ceased.

TREATMENT. It will have been observed from the cases related, that the majority of cases of glanders occurring in the human subject have been fatal; and that scarcely any plan of treatment which has been pursued has been able even to arrest the progress of the disease. Dr. Mackenzie, however, has succeeded in curing two cases by the administration of large and repeated doses of carbonate of ammonia (vide cases v and x).

The treatment which Dr. Mackenzie pursued in case v, may be arranged under the following heads: 1. An incision in each of the Whartonian ducts; 2. An emetic of ipecacuanha; 3. Sesquicarbonate of ammonia in water hourly, as concentrated as it could be swallowed; 4. An opiate at bedtime, with wine and nourishment in such quantities as the patient could be prevailed on to take.

The principal reliance was placed on the administration of sesquicarbonate of ammonia in a concentrated form. Dr. Mackenzie was led to exhibit it in this way, by the good effects he had seen it produce when so given in the severe affections of the throat, met with in malignant scarlet fever. It was an essential part of Dr. Peart's treatment of scarlatina anginosa and maligna; and he gave it in a strongly stimulating form. The following was his mode of prescribing it, as described by Dr. Willan.

"He dissolves two drachms of the carbonate of ammonia in five ounces of water, and directs the patient to take two teaspoonfuls every two, three, or four hours, according to the urgency of the symptoms. If the difficulty of swallowing abate, and the patient wish for it, a little cold water may be added to each dose. Cold water, or toast and water, may be drank at pleasure. . . . In all variations of the disease, the volatile alkali was my specific, which I administered to between two and three hundred patients *successively and successfully*."

Similar testimony is afforded by Mr. Wilkinson, and by Mr. Ricardo, of Bow.

Dr. Mackenzie says: "I cannot doubt of the utility of this particular mode of treatment, in this and the other diseases in which I have tried it. . . . I would observe, that there is much in the history of glanders which assimilates it to the more malignant forms of scarlet fever. Both, for instance, arise from a specific contagion; in both there is a similarity in the parts which are more especially implicated, viz., the throat, the respiratory mucous membrane, and the salivary glands; and in

each there is a tendency to ulceration, sloughing, and destruction of the tissue of these parts. These circumstances furnish ground for believing, *a priori*, that the medicine which would be best adapted for one disease, would be most curative of the other; and this conclusion, which is suggested by careful reflexion, is confirmed by personal observation, so far at least as the issue of the present case is concerned." (*London Journal of Medicine*, 1851, p. 798.)

CASE OF HÆMATEMESIS RAPIDLY FATAL.

In the *Lancet* for July 16th, 1853, the following case is related as having occurred in the practice of Dr. BENGE JONES, at St. George's Hospital:—

CASE. Charles D——, aged thirty-seven years, was admitted, May 17, 1853, under the care of Dr. Jones. He stated that, between six and seven on the morning of his admission, he had been seized with vomiting of blood, and that he had felt "bilious" during the previous week. He had vomited frequently during this lapse of time, but had no pain in the stomach; he had, however, a sensation as if there was a gathering at the top of his throat, and from thence the blood seemed to come. The patient brought up a great deal of blood directly after admission, and the nurse stated that there was not much the appearance of sickness, the blood seeming to rise in his throat. The man's aspect was pale, and his movements tremulous; but he had no cough, and complained of no pain whatever. Dr. Jones ordered a scruple of gallic acid three times a day, and some ice.

He continued to bring up blood during the afternoon, and at night Ruspini's styptic was given without benefit. Altogether, there were about seven pints of blood brought up whilst the patient was in the hospital, at nine or ten different times. He brought up none during the last four hours, but fell into a state of exhaustion, during which he died, at eight in the morning, the day after his admission.

POST MORTEM EXAMINATION. The body was well formed, and in good condition; a large scrotal hernia existed on the left side. On the right half of the thorax, some old pleural adhesions were found; the lungs and bronchial tubes were congested, and the latter contained a certain amount of mucous tinged with blood. Nothing further was observed in the lungs. The heart was natural, excepting some slight amount of blood extravasated beneath the endocardium of the right ventricle. The mucous membrane at the lower part of the œsophagus was opaque and thickened, and terminated by a definite prominent outline at the cardiac extremity of the stomach. This seemed at first to be a layer of fibrin or some additional substance, but was seen under the microscope to be thickened scaly epithelium, the lower prominent line being the one where the two kinds of mucous membrane meet. The stomach and intestines were to all appearance quite natural; no vascularity nor abrasion were observed; but in the stomach a pretty large clot of dark blood was found, which had, by contact, much stained the lining membrane in one place. The liver was very large, with a rough, granular appearance, and a very firm, knotted, sectional surface, of a yellow and brown parti-colour. The gall-bladder contained much tar coloured bile. The kidneys were slightly indented on their surface, and the marks corresponded to cicatrix-like seams in their cortical part, the latter being in some places diminished. The capsule of the spleen was slightly thickened, and small amounts of fibrine were collected in the divisions and lines on its surface, in some places becoming changed into firm, opaque patches. The substance of the organ was, however, natural, and no morbid alteration was observed in any of the other abdominal viscera. The muscular system generally looked very pale.

It may here be inferred that the portal circulation was greatly impeded through the "large, rough, and granular liver"; and hence the congestion of the vessels of the stomach, and the eventual unloading of the same by hæmorrhage. At first sight the case looked very much like a *bond fide* instance of idiopathic hæmatemesis, but the *post mortem* examination has shown on which visceral condition the hæmorrhage depended, and one remains still more convinced that strictly idiopathic vomiting of blood is extremely rare.

[This case recalls to our recollection some similar instances. A woman, who had for sometime been an out-patient of an hospital, for jaundice, of which she presented most visible signs, was, while attending one morning, suddenly seized with profuse hæmatemesis, of which she died in a very few hours. No *post mortem* examination was made; but we have no doubt that the struc-

tural disease of the liver stood in a causative relation to the hæmorrhage. Hæmatemesis is indeed commonly connected with congested liver, and some of the means for its relief must be such as relieve this organ: but when there is permanent structural disease, any attempt at stimulating the functions of the liver will be probably at least ineffectual, if not injurious; and the prognosis, in hæmatemesis occurring under such circumstances, must be most unfavourable.]

PHOSPHATE OF LIME IN OXALURIA.

The *Medical Times and Gazette*, for April 16th, publishes an abstract of an article in Nos. 42 and 43 of the *Medicinische Zeitung* for 1852, by Dr. KUCHENMEISTER, on the use of phosphate of lime in cases attended with the presence of oxalates in the urine. The patient was Dr. Kuchenmeister himself, who had suffered for four years from chronic diarrhœa, and other disorders of the digestive organs, accompanied with marked emaciation and hypochondriasis. The urine was acid, and very rich in crystals of oxalate of lime; specific gravity, 4.5—5.0. There was no apparent cause for the symptoms. Upon Beneke's advice, the author took daily lactate of iron, gr. ss.; phosphate of lime, grs. ii. to iii.; carbonate of lime, grs. iv. to vi. After eighty powders, the evacuations became regular, the appetite and the general aspect improved, the oxalic crystals disappeared, and the specific gravity became 2.0, 2.5.

REPORTS OF SOCIETIES.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

JUNE 1, 1853.

JAMES Y. SIMPSON, M.D., F.R.S.E., in the Chair.

BREECH PRESENTATIONS. BY CHARLES BELL, M.D.

AFTER some remarks on the great importance attributed to all malpresentations of the child by women in general, Dr. CHARLES BELL proceeded to point out the comparatively great frequency of the form of malpresentation under consideration, and its importance, scientifically and practically. He specially dwelt upon the physiological errors entertained by old authors in regard to these cases, and the bad practical rules based on them; giving also a short historical sketch of the various plans of treatment recommended.

It was to Dr. Wm. Hunter that the profession was indebted for the great modern improvement in the treatment of these cases; this improvement consisting chiefly in leaving the cases entirely to nature. But Dr. Bell thought that modern experience of the great (one in every three or four born) number of still-births, in these cases, shewed that much improvement on the recognized modern practice was possible.

Dr. Bell then proceeded to discuss the subject of the causation of breech cases; and, referring to the opinion of Lachapelle and Chailly on this subject, said, that it was an error to suppose that, in the last months of pregnancy, the fœtus became so much developed, that it could not regain its normal position if it were lying with the breech lowest. This was shewn by a reference to a point in the anatomy of the gravid uterus, at the full time, stated by Dr. Hunter, viz.: that it was never on the stretch, and that the child had always some freedom of motion. It was further known, that the presentation of the child might be changed, even after labour had commenced. Dr. Bell then referred to Dr. Simpson's researches in regard to the position of the fœtus, and added that breech cases often existed, where there was no cause but the excessive movement of the fœtus. When the child was subjected to any external irritation, it quivered in its limbs, and assumed the smallest possible dimensions, so as easily to turn. This turning was illustrated by a case in which it occurred while labour was being induced.

Dr. Bell then referred to the great importance of these cases before labour. This was illustrated by a case of great importance, as he thought that

led early in labour in some cases. In regard to treatment after labour has commenced, Dr. Bell would recommend that, as soon as the breech passes the vulva, we should proceed to deliver the head,—not so much to avoid the risk from pressure on the cord, as from separation of the placenta before the head is born.

Dr. MATTHEWS DUNCAN said, that the paper which had just been read went over such a large subject, including the discussion of the causes, treatment, etc., of pelvic presentations, that he would not take up the Society's time in following the author through it. He might state, in starting, that the peculiar views and recommendations in the paper were such, that he was constrained in regard to them to differ entirely from Dr. Bell.

And, first of all, an attempt was apparently made to show that, under ordinary circumstances, the fetus *in utero*, even at the full time, moved in the uterine cavity so freely, as to enable it to change its presentation from being one of the breech to one of the head. This was contrary to all that was ascertained and held by obstetricians to be settled, in regard to the fixedness of the presentation of either end of the ovoid of the fetus at the full time. As the fetus approached the full time, it became in size and form more and more adapted to the cavity in which it was contained; so that at last the containing cavity and the fetus were, as a general rule, so fitted to one another, that any such extensive motion as was involved in the change from a breech to a head presentation was impossible. No doubt, if the fetus were premature (as was the case in the operative examples referred to by Dr. Bell), or very small, or if the quantity of liquor amnii were excessive, such extensive movements might in these circumstances take place. But these were exceptions to the general rule.

Dr. Bell had alluded to a fact, noted by Dr. Hunter, namely, that the uterine walls were not distended to the utmost, but that they appeared loose, and as if the cavity could easily contain more than was in it. This resulted chiefly from the quiescent or relaxed state of the fibres of the gravid uterus, and was no reason for thinking that the capability of further distension could be very great at the full time. Dr. Hunter's authority, so far from supporting Dr. Bell's view, as he seemed to think, was entirely and decidedly against it; for, in his admirable lectures on the anatomy of the gravid uterus, he stated his opinion that, in the latter months of gestation, the fetus had commonly so little room, and was so closely fitted to the uterus, that it could not change its general position by its own motions, or even by accidents to the mother.

There was no doubt that, although the child could not move to any extent on its transverse axis at the full time, it could move upon its long axis. And the movements or circumvolutions upon its long axis afforded the general explanation of the rollings of the cord around the neck to which Dr. Bell had alluded. Dr. Bell had referred to the researches of Dr. Simpson, in regard to the positions of the fetus *in utero*. But, while he professed his accordance with the views of that author, he evidently discarded the various explanations given by him of the causes of malpresentation, and resorted in the cases he had quoted to the antiquated notion that breech presentations were produced by frights, succussions, accidents, etc., at or near the full time.

The recommendation to interfere with the labour as soon as some part of the body of the child was born, must be altogether condemned. The beautiful mechanism of natural parturition in breech cases would be inevitably deranged, the chin would be liable to be displaced upwards by extension of the foetal head, and elevation of the arms would be also liable to be produced, both of which changes would be very injurious and dangerous to the mother and child.

There was very little cause why an uncomplicated breech presentation in a healthy female should be more dangerous than a head presentation. The researches of Dr. Simpson and of others to which Dr. Bell attended, showed that the existence of breech presentation was frequently dependent on morbid states in the mother and fetus; and Dr. Duncan believed that the greater danger to the mother of labour in breech presentations, arose either from these morbid causes simply, or from their effects in perverting the mechanism of the labour, and complicating it, not from the fact alone of the breech presenting.

Dr. BELL replied that he was sorry that Dr. Duncan had misunderstood his paper. He had not thrown aside all Professor Simpson's views; on the contrary, he considered that they give the most rational explanation of the natural position of the fetus, and enable us to account for the preternatural. It is quite clear that it is the impression made by the uterus on the fetus, inducing it to exert stronger reflex movements, which in many cases produces the change in its position; and in others

the change is the result of concussion. Hence we have malpresentation induced by the injecting of tepid water into the vagina. With regard to the opinion of Dr. Hunter, he had quoted his own words, to show that the uterus is an elastic body, which is never so full as to be on the stretch. He could not see, therefore, how it could in any way prevent the change in the position of the fetus, unless some unusual circumstance occurred. He believed that at no time of gestation was the fetus immovably fixed, before the escape of the liquor amnii, or the uterine contractions, had commenced. This was proved by the case quoted by Baudelocque, in which the child changed its position several times during parturition. He had also frequently felt the head of the child roll under his hand, when put on the abdomen of the mother, in cases of spurious pains in the latter end of gestation. On such occasions, he has observed the head to be raised as high as the navel during the spasm, and to again subside into the pelvis when the pains went off.

Dr. SIMPSON said, that he had seen a case where the presentation of the child changed after labour was begun, as Dr. C. Bell had described. He thought Dr. Bell had omitted to consider that, in cases of induction of labour by the douche or otherwise, the child was premature and small, and the motions consequently much fewer than at the full time. The statement of Dr. Bell in regard to the danger to the child from separation of the placenta, he believed to be new and important.

PARALYSIS OF THE COMMON MOTOR OCULI NERVE.

BY JOHN STRUTHERS, M.D.

Dr. JOHN STRUTHERS read an interesting case of this affection, supervening on exposure to cold, with an account of the *post mortem* examination.

The muscles supplied by the nerve were completely paralysed. The eye could be easily moved outwards. The pupil was much enlarged, and did not contract under the strongest light. Vision with the affected eye was entire, as also common sensibility. Under treatment, the paralysis of the voluntary muscles gradually diminished; but the fixed dilatation of the pupil was much slower of disappearance. The man, not long afterwards, died of apoplexy. On the *post mortem* examination, it was found that the motor oculi nerve on the affected side was about one-third smaller than on the other side, and was of a browner tint than the other nerves. Under the microscope, the nerve-tubes were observed to be about half the size of those of the nerve of the side not affected, and also less distinct. The muscles supplied by the affected nerve were also somewhat atrophied.

In his attendance on this case, Dr. Struthers had made an interesting physiological observation; namely, that although the third nerve and iris were paralysed, yet belladonna exerted its usual dilating power over the affected iris.

ASSOCIATION INTELLIGENCE.

ANNIVERSARY BRANCH MEETINGS ALREADY ANNOUNCED.

BRANCH.	DAY AND HOUR.	PLACE.
Shropshire Branch.	Tuesday, 26th inst. Noon.	George Hotel, Shrewsbury.
South-Western Branch.	Wednesday, 27th inst., 1 P.M.	Webb's Royal Hotel, Torquay.

MONMOUTHSHIRE AND SOUTH WALES BRANCH: ANNUAL MEETING.

[Report continued from p. 626 of last number.]

Mr. MICHAEL, the Hon. Secretary, then read the following report, which had been agreed upon by the Council:—

REPORT OF THE COUNCIL.

"Your Council, in presenting its First Annual Report to the Members of the Monmouthshire and South Wales Branch of the Association, beg to congratulate them upon the satisfactory condition of the Branch.

"At the commencement of the year, there were seventy-five members; since that time, one member, Dr. Price, of Monmouth, has, for the present, declined membership; one gentleman, Mr. Robertson, has left South Wales; and nine gentlemen have enrolled their names as members, viz.: Mr. Anthony (Tredegar); Mr. King (Chepstow); Mr. Roberts (Aberdare);

Mr. T. Evans (Cardiff); Mr. D. Lawrence (Pontypool); Mr. G. Watkins (Chepstow); Mr. E. Robathan (Risca); Mr. W. W. Morgan (Newport); and Mr. Audland (Tintern)—making the present total number of members eighty-two.

"The expenses during the year ending April 9th, 1883, have amounted to £9:12, of which the following are the particulars:

Books, stationery, printing, etc.	£2	16	0
Postages		1	10 0
Expenses of meetings	£0	3	6
Ditto ditto	0	2	6—0 0 0
Share of Autographic Press		5	0 0
	£9	12	0

"Much of the expenses of printing, etc., will be, in future, spared, by the autographic press, which is the joint property of the Branch and the Medico-Ethical Society. But, with eighty-two members, there must still be expenses which cannot be estimated at less than £5 per annum, for postages, stationery, books, attendance, etc.

"Your Council, feeling desirous of affording as much aid as possible to the Parent Society, suggest, especially as they would wish by all means in their power to support the Journal in its present greatly improved form, that it may be desirable for the members of the Branch Association in future to contribute 2s. 6d. per annum each to a fund, which will thus bring in £10 per annum—£5 of which, they suggest, should be voted annually to the hon. secretary, to cover all expenses of conducting the business of the Branch; and £5 to the Medical Benevolent Fund—a society to which, the Council much regret, they have had no power of lending assistance during the past year, and which they believe, in a humble and unostentatious manner, is effecting much good, by relieving sufferings and distresses greater than should ever fall to the lot of the fatherless and widows of a profession devoted to the relief of suffering humanity.

"Your Council would wish to refer to the fact of the annual meeting of the Association being this year fixed for Swansea, and trust that their successors in office may receive that kindness and support from their fellow members, and the profession generally, which has been manifested towards themselves during the past year, in preparing for the reception of the Association in a manner creditable alike to the Principality, the profession, and the Monmouthshire and the South Wales Branch of the Provincial Medical and Surgical Association.

"Your Council have had brought under their notice both the Medical Reform and Vaccination Bills, but have thought it right to defer action in the matter until the opinion of the medical brethren assembled at the annual meeting could be learned.

"In resigning their trust, your Council would recommend, as more likely to be generally acceptable, that the members of the Branch should have the power of naming the Council for their own district; and that, with a view to such nomination, the hon. secretary be requested in future to send round to the Branch, one month before the annual meeting, a list of the members; and that each be entitled to vote for twelve councillors, in the following order:—Pembrokeshire, 1; Carmarthenshire, 2; Swansea and neighbourhood, up to Cowbridge, 3; and Merthyr, Chepstow, Newport, Abergavenny, Pontypool, and Cardiff, 1 each.

"In conclusion, your Council wish to thank the members for the kind consideration they have received from them during their year of office, and to express the gratification they feel in witnessing the prosperity of an Association which they believe calculated to benefit both the profession and the public."

Dr. STEELE moved, Dr. BIRD seconded, and it was resolved,

"That the Report of the Council now read be received and adopted."

OFFICERS AND PLACE OF MEETING FOR ENSUING YEAR.

Mr. F. C. BATT moved, Mr. E. DAVIES seconded, and it was resolved,—

"That Mr. J. L. WHITE be the President-elect for the ensuing year; and that the next annual meeting of the Branch be held at Merthyr, at such time as local circumstances may render most convenient."

[Mr. E. Davies was solicited, previously to the adoption of this resolution, to accept the office of President, but declined, from a pressure of engagements.]

It was moved by Mr. CHERRY, seconded by Mr. BATT, and resolved,—

"That the following gentlemen be nominated as the Council for the ensuing year: EX-OFFICIO MEMBERS: the President-elect,

President, and Ex-President: Mr. J. D. Brown (Pembrokeshire); Dr. Lawrence, Mr. B. Thomas (Carmarthenshire); Mr. H. L. Prichard, Mr. J. French, Mr. W. Rowland (Swansea); Mr. T. J. Dyke (Merthyr); Mr. T. King (Chepstow); Mr. Jehoiada Brewer (Newport); Mr. E. Y. Steele (Abergavenny); Mr. J. Essex (Pontypool); Mr. J. Lewis (Cardiff)."

THE SWANSEA MEETING.

Mr. E. DAVIES moved, Mr. WILLIAMS seconded, and it was resolved,—

"That this Branch express their gratification at the prospect of meeting their professional brethren at Swansea, at the annual meeting of the Association; and that the members of the Association be invited by this Branch to a *soirée*, to be held at the National School Rooms, Swansea, on Wednesday evening, August 11th, at eight o'clock.

LORD LYTTELTON'S VACCINATION BILL.

Mr. E. EVANS proposed, Dr. BIRD seconded, and it was unanimously resolved,—

"That a petition be presented to the House of Commons against certain clauses in the Vaccination Extension Bill of Lord Lyttelton; and that a clause be added, nominating all duly qualified medical men public vaccinators; that the fee allowed be 2s. 6d. (instead of 1s. 6d., the present fee), in consideration of the additional duties to be imposed by the proposed measure."

This motion gave rise to an animated discussion, in which Mr. Evans, Mr. Michael, Dr. Bird, Mr. Williams, Mr. Morgan, Mr. Audland, and Dr. Steele, contended that vaccination ought to be made compulsory. Dr. Edwards had grave doubts as to the propriety of adopting the principle of compulsion. All of the speakers adverted to the necessity of impressing upon the legislature the claims of the medical profession to be justly dealt with in any such measure as that of Lord Lyttelton.

MEDICAL REFORM.

It was moved by Mr. WATKINS, seconded by Mr. ESSEX, and resolved,—

"That the Secretary be requested to prepare a petition to the House of Commons in favour of the Medical Reform Bill, to be signed by the President on behalf of the members of the Monmouthshire and South Wales Branch of the Provincial Medical and Surgical Association."

THANKS TO RETIRING OFFICERS, ETC., ETC.

Dr. STACK moved, Mr. ROGERS seconded, and it was unanimously resolved,—

"That the thanks of this meeting be given to the Council, for their services during the past year."

Dr. EDWARDS moved, Mr. EVANS seconded, and it was resolved,—

"That the thanks of this meeting be given to Mr. Michael, for his excellent services as Secretary; and that he be appointed Secretary for the ensuing year."

Mr. EVANS moved, Dr. SYLVESTER seconded, and it was resolved,—

"That, in future, the charge for the annual dinner (now one guinea) be 10s. 6d."

Dr. SYLVESTER moved, Mr. MICHAEL seconded, and it was resolved,—

"That the thanks of this meeting be given to Dr. Morris, for his able and impartial conduct in the chair."

The PRESIDENT having briefly acknowledged the vote, the meeting separated, and met, at half-past five o'clock, at the Beaufort Hotel, at

THE DINNER,

which had been provided, in the accustomed excellent style of that famed hostelry, for the members and their friends.

Dr. MORRIS presided; and Mr. MICHAEL occupied the vice-chair. After dinner the chairman gave "The Queen," "Prince Albert, and the rest of the Royal Family"; "the Bishops and Clergy of the Diocese" (acknowledged by the Rev. J. R. Gurnall); "the Army and Navy"; "the Lord Lieutenant of the County" (acknowledged by J. L. Baldwin, Esq.). Other toasts named, viz.: "the President", by Dr. Bird; "the Hon. Secretary", by Dr. Morris; "the President-elect", by Dr. Morris; "the Council, Sir Charles Hastings"; "the Hon. Secretary"; "Kindred Associations in Ireland, and Scotland, having for their object the advancement of sound medical knowledge, and the elevation of the medical profession", by Mr. King.

SOUTH EASTERN BRANCH: ANNUAL MEETING.

The Annual Meeting of the South Eastern Branch took place at Tunbridge Wells, on Wednesday, June 29th, under the presidency of Isaac Hargraves, Esq.

The following members were present:—Joseph H. Baller, Esq. (Penshurst); J. M. Barry, M.D. (Tunbridge Wells); William Bayes, M.D. (Brighton); G. Bottomley, Esq. (Croydon); J. Cordy Burrows, Esq. (Brighton); Joseph Delves, Esq. (Tunbridge Wells); Robert Duncan, Esq. (Tunbridge Wells); H. M. Gould, Esq. (Watlington); Richard Gravely, Esq. (Newick); William A. Greenhill, M.D. (Hastings); Isaac Hargraves, Esq. (Tunbridge Wells), President; Constantine Holman, M.D. (Reigate); Thomas Hunt, Esq. (London); G. Bell Irving, Esq. (Lamberhurst); Robert M. Rathill, Esq. (Westerham); Edward Ray, Esq. (Dulwich); Peter Roscoe, Esq. (Folkestone); Frederick Sankey, Esq. (Wingham); W. C. Satchell, Esq. (Tunbridge Wells); Amelius Sicard, Esq. (Bridge, near Canterbury); Thomas H. Silvester, M.D. (Clapham); James Stedman, Esq. (Guildford); Charles M. Thompson, Esq. (Westerham); Charles Trustram, Esq. (Tunbridge Wells); Richard Turner, Esq. (Tunbridge Wells); Henry B. Tuttiell, Esq. (Ventnor); William Wallis, Esq. (Hartfield); Henry Whitfield, Esq. (Ashford); J. L. Worship, Esq. (Riverhead).

The chair having been vacated by FREDERICK SANKEY, Esq., was taken by ISAAC HARGRAVES, Esq.

PRESIDENT'S ADDRESS.

After an exordium referring to matters local and personal, to the Income Tax question, and to other topics of interest, the President thus proceeded:—

MEDICAL REFORM is now under parliamentary consideration, and will probably occupy your attention to-day. I must confess that I think the medical corporate bodies might do the thing better than the legislature; the Colleges of Physicians and Surgeons have already advanced some steps in the right direction. Lawyers regulate themselves; and if we had the same *esprit de corps* which they have, we might do the same. This Association has done great good in bringing us together in social contact, and diffusing amongst us a more harmonious feeling, which must ultimately lead to happy results.

THE VACCINATION BILL deserves your anxious attention. A petition concerning it will be laid before you.

THE JOURNAL. The very improved state of our Journal is highly satisfactory; and I trust that your general approval of it will stimulate continued exertions.

MEDICAL BENEVOLENT COLLEGE. The success which has attended Mr. Probert's exertions in the cause of the Medical Benevolent College is highly gratifying; and doubtless it will become a valuable acquisition, an ornament and a honour to our profession, out of which nothing but good can come. To the kind sympathy of a generous public in this great work, we owe much gratitude for the extensive support they have given it.

PHOTOGRAPHY, from the rapidity and truthfulness with which it pictures objects of deep interest which run into too rapid decomposition for the draughtsman, is a great acquisition to pathology; and in connexion with the microscope, produces wonderful results. Some beautiful specimens of the art of photography, through the kindness of my friend Mr. DELVES, I am enabled to exhibit to this meeting.

After expressing regret at the necessary absence of the secretary, Mr. Hargraves concluded by calling upon his substitute, Dr. HOLMAN, to read the Report of the Council.

REPORT OF THE COUNCIL.

Dr. SOULBY. In reporting the proceedings of the past year, the Council desire to commence by giving expression to the regret which has been universally felt by the members, at the death of their lamented president, Dr. Soulby. Although the advancing progress of the malady which eventually proved fatal, prevented Dr. Soulby from presiding over the meeting at Folkestone, yet the members of the South Eastern Branch were too well acquainted with the honest, open, and friendly character of their late associate—not to speak of his high professional attainments, which were well known to all those who had the advantage of his friendship—not to feel much sorrow at the loss which has been sustained by the Branch and by the Association.

THE JOURNAL. At the Folkestone meeting, it will be recollected that a motion was carried, calling the attention of the general meeting at Oxford to the condition of the Journal. The proceedings at that meeting are matter of notoriety; and the committee think they may congratulate the members on the improvement which has taken place in the character of the Journal. They trust that it will always be borne in mind that the func-

tions of a Journal, the organ of an Association like ours, can never be entirely similar to those of a publication emanating from a single mind, and owning no responsibility to any but a single proprietor. The special mission of our Journal should be the announcement of the proceedings of the Association, and the publication of facts connected with the progress of medical science to the remote points in which members reside.

MEDICAL REFORM. With regard to Medical Reform, the Bill of the Association is now before the members. It will be for this meeting to decide whether it should now express any opinion on the Bill. The committee believe that the chief difficulty will reside in the formation of the governing council; for the framers of the bill have not been able, in the formation of the council, to carry out the representative principle, which has hitherto been one of the main points on which the Association has rested.

The Colleges of Physicians and Surgeons will be represented in the council by members chosen by those colleges; but the great body of general practitioners not enjoying the franchise in either of those colleges will be represented only by gentlemen delegated *ad hoc* by the Secretary of State. This may work well in practice; but undoubtedly it is a derogation from one of the leading principles of the Association, and shows forcibly the want of an organisation in that class of the profession whose interests are thus taken out of their own hands, and vicariously cared for.

INCOME TAX. The adjustment of the income tax as affecting precarious incomes has been a leading topic during the last year. The committee did not deem it advisable to call a special meeting of the Branch on the subject; and, since the appearance of the Budget of the Chancellor of the Exchequer, they have not, whilst still maintaining the unfairness of the present amount of assessment on the medical profession, felt that there was much ground for expecting relief from the legislature. The consideration also, that there is a prospect of the final abolition of the tax in 1860, induces your committee not to recommend any further agitation on the subject.

THE VACCINATION BILL carried through the House of Lords by Lord Lyttelton now rests in the House of Commons. That more effective means of extending vaccination are desirable there cannot be a doubt; but the present bill, besides being really impracticable in its enactments, imposes too much on the already overburdened readiness of the medical profession to work for the public good. Your committee strongly recommend the adoption by the Branch of a petition against the bill.

Considerable discussion followed the reading of the report upon the different topics mentioned in it.

It was moved by Mr. CORDY BURROWS, of Brighton, seconded by Dr. BAYES, of Brighton, and carried—

"That the Report now read be received by the members, and entered on the minutes."

MEDICAL REFORM.

It was moved by Mr. TRUSTRAM, of Tunbridge Wells, seconded by Mr. CORDY BURROWS, and carried:

"That this meeting considers that the want of a direct representation of the general body of the profession in the council, as proposed in the Reform Bill of the Association, prevents the Bill from receiving the support and approval of this meeting; and that a copy of this resolution be forwarded to the parties in charge of the Bill."

[Mr. BOTTOMLEY, upon arriving after this resolution had passed, expressed regret at his absence, as he was prepared to have opposed it.]

THANKS TO RETIRING OFFICERS.

It was moved by THOMAS HUNT, Esq., of London, seconded by HENRY WHITFIELD, Esq., of Ashford, and carried:

"That the thanks of this Branch are due, and are hereby offered to Mr. SANKEY, the acting President for the last year, and to the other officers of the Branch."

PLACE OF MEETING IN 1854: ELECTION OF OFFICERS.

A requisition, numerously signed by the medical practitioners in Chichester and its neighbourhood, inviting the Branch to hold its annual meeting in that city in June 1854, was presented.

Mr. TRUSTRAM moved, and Mr. SANKEY, of Wingham, seconded:

"That the General Meeting for 1854 be held at Chichester; and that the following gentlemen be requested to act as officers for the year.

"President: J. M'Carogher, M.D. Vice-Presidents: N. Tyacke, M.D.; Allen Duke, Esq. Council: R. Elliott, Esq., Chichester; C. Hurlstone, Esq., Chichester; W. Caffin, Esq., Chichester; G. Bottomley, Esq., Croydon; J. C. Burrows, Esq.,

Brighton; Wm. Newnham, Esq., Farnham; W. Bayes, M.D., Brighton; W. A. Greenhill, M.D., Hastings; P. Blakiston, M.D., St. Leonard's-on-Sea."

DESIGNATION OF THE PARENT ASSOCIATION.

It was moved by J. C. BURROWS, Esq., seconded by CHARLES TRUSTRAM, Esq., and carried:

"That the General Council of the Association be requested to consider the desirability of altering the name of the Parent Association to that of the 'British Medical and Surgical Association.'"

LORD LYTTELTON'S VACCINATION BILL.

The following resolution was adopted:—

"That, in the opinion of this Meeting, the Bill for the extension of Vaccination, now before the House of Commons, is in many respects objectionable; and that a petition against the Bill in its present shape be adopted; that it be signed by the Chairman on behalf of the Meeting; and that Thomas Alcock, Esq., M.P. for East Surrey, be requested to present it to the House of Commons."

The following is the petition which was adopted:—

To the Honourable the Commons of Great Britain and Ireland in Parliament assembled.

The humble petition of the Members of the South-Eastern Branch of the Provincial Medical and Surgical Association, sheweth—

That there is now before your Honourable House a Bill for the promotion of Vaccination, and for rendering Vaccination compulsory among all classes of Her Majesty's subjects.

That your petitioners are most anxious for the adoption of all well considered means for the extension of vaccination, but that some of the provisions of the Bill in question are objectionable, and will tend to interfere with the success of the measure.

That the clause compelling vaccinators to vaccinate in all cases directly from the arm is unnecessary, in remote places very frequently impracticable, and could not be enforced.

That the Bill does not contain any enactment compelling the parents of vaccinated children to bring their children for inspection, without which registration would be very imperfectly carried out.

That the Bill does not contain any sufficient provision for the remuneration of vaccinators; that the payment made to them under the present system is for the most part insufficient; and that the Bill in question imposes new duties on them, in one instance of an objectionable character, without providing any remuneration—thus injuriously affecting the medical profession.

Your petitioners therefore pray that your Honourable House will not pass the Bill in its present form, but will refer it to a select committee, who may take evidence of competent persons, and your petitioners believe that a Bill may thus be framed which will be acceptable to the public and to the medical profession, and will be successful in the object proposed, viz., the extension of vaccination, and thereby the diminution, and it is hoped, under Providence, the eventual extinction of small-pox.

And your petitioners, as in duty bound, shall ever pray.

(Signed) ISAAC HARGRAVES, *Chairman*.

PHTHISIS IN HASTINGS. BY W. A. GREENHILL, M.D.

Dr. GREENHILL made some remarks on the ratio of mortality from phthisis in Hastings, as influenced by the number of strangers who die there. Dr. Greenhill's communication was followed by an interesting and lengthened discussion.

MEDICAL ATTENDANCE ON SICK CLUBS. BY J. REID, ESQ.

Mr. REID, of Canterbury, made the following communication: When the South-Eastern Branch of the Association met at Tunbridge Wells in 1848, Mr. Thompson, of Westerham, introduced the subject of medical clubs to the meeting, and in a forcible and eloquent speech pointed out many of the evils arising from them; laying particular stress upon the unnatural and injurious rivalry and jealousy that was frequently created on their account, and the gross imposition that was practised upon the profession. The general feeling of the meeting agreed with Mr. Thompson's observations, and certain resolutions were unanimously passed. A subcommittee was formed to carry out these resolutions, and to make a report at the next meeting. I was not present at the meeting at Brighton in the following year, but from the printed report it appears that the subject was again brought before the Association, and the report of the progress which had been effected during the year was made by Mr. Thompson. No specific result had been obtained; but the feeling of the members present seemed again in favour of seeking and applying some remedy. No further allusion to the

subject appears in the printed reports, nor do I remember to have heard any further remarks upon the subject at the subsequent meetings that I have attended.

The remarks made at the meeting at Tunbridge Wells in 1848, impressed me strongly with some of the evils of the existing club system; and I have been anxious ever since to see a fairer and more equitable plan adopted, by which the real benefit of medical aid might be ensured to the industrious and prudent labourer alone. It was, therefore, very satisfactory to find that, in the latter part of last year, circumstances existed which made it probable that something might be definitely effected on this point in Canterbury.

The evils of the system had been long acknowledged and felt by most of the profession, to the extent with some of many condemning the entire system of the connexion of medical men with clubs and friendly societies, etc. Although this feeling was strong, yet the degree of mutual confidence and reliance was not such as to insure a uniform mode of action. In September 1852, a better prospect appeared, and it seemed likely that mutual understanding might be come to.

The members of the profession particularly interested in the subject met, and adopted the following agreement, which had been drawn up in accordance with the spirit of what had been urged at the meetings of the South-Eastern Branch of the Association. It was signed by all present, and other members of the profession subsequently added their names, as wishing to sanction the agreement.

COPY OF THE AGREEMENT

relating to Medical Clubs and Friendly Societies, signed by members of the medical profession in Canterbury.

Canterbury, Oct. 8th, 1852.

It having fallen within our knowledge and experience that the professional services rendered by medical men, in this city and neighbourhood, to friendly societies and medical clubs, are received, under cover of membership, by persons whose pecuniary circumstances and position in society place them above the necessity of using privileges intended for a more needy class, we agree that it is advisable to adopt means for modifying a system which so materially injures the interests of the profession, and induces many, covertly and unjustly, to avail themselves of its charitable tendency.

Whilst we approve of the present system of medical attendance by the surgeons of friendly societies and medical clubs, so far as it is the means of adding to the independent character of the mechanic and farm labourer, and of aiding them in the time of sickness, we are strongly of opinion that the benefit of such assistance should be strictly limited to the working classes, and that master tradesmen, and persons above the rank and means of the day labourer, ought not to receive or avail themselves of such privileges.

We, therefore, agree and pledge ourselves, for the future, not to hold any professional appointment to, or engage with any friendly society or medical club, etc., unless the society or club guarantees that the services required of us shall be limited to the class of persons before specified as the proper recipients of such services.

In order distinctly to define the class we indicate by the term mechanic, farm labourer, day labourer, etc., we agree to include in it all those whose wages and means are equivalent to twenty shillings a week and under.

It may be well to add, that beyond the confidence and honourable trust we hereby place in one another, we consider it incumbent on each of us, in order to carry out an agreement like the present, to cultivate a mutual respect and forbearance as regards each other's interests.

(Signed) THOMAS ANDREWS.
THOMAS SANKEY COOPER.
CHAS. HOLTTUM.
GEORGE RIGDEN.
ALFRED B. ANDREWS.

JAMES REID.
WILLIAM JAMESON.
CHARLES HOWELL.
HENRY DEKKE.
WM. EVANS.

With regard to the sum of 20s., fixed upon in the agreement, it should be observed, that it was decided upon as giving a wide margin to the class of persons indicated. It was known that many, receiving only 12s. or 15s. a week, were not content with the customary charges of their medical attendance, which, of course, much exceeded the payment made by the member. It was felt that, in the absence of any satisfactory information on the point, whatever the limit might be more or less arbitrary; and there would be no just above the limit, that would consider it a duty to attend their own case.

The result of this agreement, up to the present time, has been very satisfactory. There were four societies in Canterbury, which had surgeons attached to them upon the usual plan of payment. Three of these have modified their rules, in accordance with the requirement of the profession; the fourth is only waiting for the appointed time to consider the matter; for it was resolved, at the meeting of medical men, that sufficient time should be allowed the clubs to modify their rules, if they were so disposed, as many could only do so at their annual meeting. Some difficulty occurred with the Manchester Unity, but it was finally settled, as the accompanying printed paper will show. As the society is one that is widely spread through the kingdom, and one in which the evil sought to be remedied exists to a great degree, and as the alteration made in its by-law has been confirmed by Mr. Tidd Pratt, the decision may be considered as an important one, and one that will materially assist in forming a precedent in any district where it may be desired to take a similar step to that made at Canterbury. Should the fourth society, before alluded to, not think fit to alter its regulations, the surgeon who at present acts for them will leave them, and they will be unable to obtain a surgeon in the neighbourhood.

The step which has been taken relates principally to one of the evils only of the club system, namely, the abuse that is made of the services of medical men; but in that step I think a remedy, to some extent, is implied against the other evils which involve, and are injurious to, the proper harmonious feeling that should exist amongst members of the profession in every district. I would especially point to the last sentence of the agreement, as the basis upon which every similar plan should be placed, in order to be effectually carried out; and would add, that, in carrying out that principle to its full extent, less of the mercenary, and more of the charitable view, will be entertained, as regards the benefit accruing from club appointments.

Mr. THOMPSON (of Westerham) stated that as chairman of a committee appointed by the Branch in 1848 to consider the subject of medical attendance on clubs, he was well aware of the very great abuses which arose from this system of attendance upon the classes just above pauperism.

MALIGNANT DISEASE.

Mr. DELVES read a report of two cases of malignant disease, which had been under the care of Mr. Hargraves in the Tunbridge Wells Infirmary, and which were interesting on account of their rapid progress.

THE DINNER: PRESENTATION OF A TESTIMONIAL TO THOMAS MARTIN, ESQ.

The business of the day being concluded, the members sat down to dinner—at the conclusion of which, after the usual loyal toasts—Mr. Hargraves proposed in terms of handsome eulogy the health of the late secretary of the South Eastern Branch, Thomas Martin, Esq., of Reigate, who attended the meeting this day at his request. He called upon Mr. Bottomley, of Croydon, to present to Mr. Martin in the name of the subscribers, a very handsome offering in the shape of an ornamental timepiece.

Mr. BOTTOMLEY recalled to the recollection of the meeting, that, at the last annual meeting at Folkestone, it had been determined to present to Mr. Martin a testimonial of the regard of the members, on the occasion of his retirement from the office of Secretary; and the timepiece now before them was the result of the subscription then commenced. Mr. Bottomley alluded to the various services rendered by Mr. Martin to the profession, in founding the Surrey Medical Benevolent Society, in 1812,—a society which had been very useful, not only in relieving the wants of the widows and children of its members, but in keeping up an improved social feeling among the practitioners of the county. This society had greatly added to the scope of its usefulness, by having recently subscribed the sum of two thousand five hundred pounds towards the building and endowment of the Medical Benevolent College, which he trusted would have the support of every medical practitioner in England. Mr. Martin had also been the founder of the South-Eastern Branch of the Provincial Medical and Surgical Association, which again brought together a larger number of medical practitioners, who, by their united efforts, maintained the dignity, prosperity, and usefulness of the healing art. For these, and many other acts, so laudable in their objects, and emanating from one who had all his life addicted himself to acts of benevolence, and done so much for the support and dignity of the medical profession, in the name of the South-Eastern Branch, he begged Mr. Martin to accept a timepiece, as a small token of regard and esteem, trusting that he would live long to look upon it, and, whenever he did so, he would feel that he was esteemed and respected by the members of this Branch.

Mr. MARTIN, in rising to express his best thanks for the handsome present, and the terms of honourable distinction which had been conferred upon him, observed, that most of the gentlemen then assembled were not aware that he was the oldest Tunbridge Wells practitioner then present, having officiated as assistant to the late Mr. Prince for fifteen months, in the years 1798 and 1799; of which period of time, and the events which occurred to him, both professional and social, he entertained a pleasing recollection. Having been engaged in the practice of medicine for such a long series of years, he felt it a duty to retire from its active pursuit, and, at the same time, to decline a re-election to the office of Secretary and Treasurer to the South-Eastern Branch of the Association,—a position which had brought him more particularly acquainted with the gentlemen then present, and others who were absent; for all of whom he entertained sentiments of the greatest respect. In co-operating with his brother members of the South-Eastern Branch to carry out the objects of the Association, he had always experienced the highest gratification: and, in retiring from his official connexion with them, he had his great reward, in the cordial expression of their kindly feelings of friendship; for which he desired permission most respectfully and gratefully to thank the gentlemen who had been instrumental in presenting to him so handsome and complimentary a testimonial.

METROPOLITAN COUNTIES BRANCH. ANNUAL MEETING.

The First Annual Meeting was held on Tuesday, the 19th instant, at the Brunswick Hotel, Blackwall. The following gentlemen were present:—

E. B. Bowman, M.D. (Dalston); W. J. Bryant, Esq. (Bathurst Street, Sussex Square); Charles T. Carter, Esq. (Hadley); Thomas Charles, Esq. (Lower Belgrave Place, Pimlico); W. Collyns, Esq. (Harlow); John Rose Cormack, M.D. (Putney); John Davies, M.D. (Hertford); Robert Elliot, Esq. (Denmark Hill, Camberwell); John Forbes, M.D. (Old Burlington Street), President; John Grabham, M.D. (Islington); George Grant, M.D. (Richmond); Alexander Halley, M.D. (Queen Anne Street, Cavendish Square); Alexander Henry, M.D. (Alfred Street, Bedford Square); Edwin Howard, M.D. (Harley Street, Cavendish Square); Thomas Hunt, Esq. (Alfred Place, Bedford Square); Charles F. J. Lord, Esq. (Hampstead); William O'Connor, M.D., (George Street, Portman Square); J. Propert, Esq. (Old Cavendish Street); John Pursell, M.D. (Harleyford Place, Kennington Common); Edgar Sheppard, Esq. (Enfield); F. Sibson, M.D. (Lower Brook Street); W. Tyler Smith, M.D. (Upper Grosvenor Street); Joseph Toynbee, Esq. (Saville Row); T. Ogier Ward, M.D. (Kensington); George Webster, M.D. (Dulwich); Thomas Workman, Esq. (Bayswater).

At four o'clock Dr. Forbes took the Chair, and after a few gratulatory remarks upon the progress and prosperity of the Association, called upon Dr. T. O. Ward, the *Honorary Secretary*, to read the Report of the Council.

* "No. 982, a. INDEPENDENT ORDER OF ODD FELLOWS, MANCHESTER UNITY, CITY OF CANTERBURY LODGE. At a summoned committee of the whole of the members of the above Lodge, on Monday, Nov. 29th, 1852, the following propositions were unanimously agreed to: That the 16th bye law be erased, and the following substituted:—

"That Thomas Sankey Cooper, Esq., be the surgeon of this Lodge, and remain in office during the pleasure of the Lodge; and whose duty it shall be to examine all candidates for admission, to attend, prescribe, and supply medicines, leeches, etc., to the sick members, whose average earnings do not exceed £1 per week, and who are clear on the books of the Lodge, whether they claim the sick gift or not; and that for the above, he shall receive 4s. 4d. per annum each member, payable quarterly: the said surgeon shall also attend, prescribe, and supply medicines, leeches, etc., to those members whose incomes exceed £1 per week; and that his charges for the same be paid from the Incidental Expenses Fund. (Members engaging other than the Lodge surgeon, to be deprived of the said provision.)

"Any member requiring the advice of the surgeon, shall produce to him his contribution card, at the time of applying for the same. Members to return or pay for all bottles, etc.

"That the surgeon's circle comprise a distance of two miles from the city, and that he be paid 1s. per mile each visit beyond that distance; the mileage of members beyond two miles and under five miles, to be paid from the Incidental Expenses Fund; but members beyond the distance of five miles requiring his assistance, to pay 1s. per mile each visit over the aforesaid five miles. Fractures, dislocations, etc., to be paid for extra.

"William Pilch, G.M., George Norton, N.G., James Nightingale, V.G., John W. Thomas, Permanent Secretary.

"REGISTRAR'S CERTIFICATE. I hereby certify, that these alterations of rules are in conformity to law, and to the provisions of the statute in force relating to registered friendly societies.

JOHN TIDD PRATT,
The Registrar of Friendly Societies in England.

"Copy kept, J. TIDD PRATT.

18th day of Feb. 1853."

REPORT OF THE COUNCIL.

In presenting their first Annual Report, the Council of the Metropolitan Counties Branch of the Provincial Medical and Surgical Association think it desirable that the attention of the members of the Branch should be recalled to the circumstances under which it was established, in order that they may be enabled to judge how far the hopes entertained with regard to its usefulness have been realized.

At the last anniversary meeting of the parent Association in Oxford, the number of members resident in and around the metropolis was fifty-seven. It was then thought by some of them, that the medico-political objects of the Association, such as Medical Reform, the suppression of quackery, etc., might be promoted by the formation of a Metropolitan District Branch, which, by holding frequent meetings, and taking advantage of the facilities for communication, might exercise greater influence than could be exercised by any of its individual members, however eminent and respected. It was also believed that, by the formation of an active Branch in their immediate vicinity, the great body of metropolitan practitioners might soon be led to take an interest in the Association and to join its ranks, and thus co-operate with the provincial medical men for the furtherance of the interests of the profession throughout the kingdom.

It having been found that a considerable number of the members of the Association participated in this view, and that it also met with the concurrence of Sir Charles Hastings, the founder of the Association and president of the General Council, a preliminary meeting was held on Nov. 26, 1852, when Dr. Forbes took the chair. It was then resolved to call a General Meeting of the members of the Association, residing within thirty miles of London.

The first general meeting was held on January 11, 1853, when it was determined to establish a Branch, including the metropolis and such parts of the adjoining counties as are not included in any other Branch, under the name of the Metropolitan Counties Branch; laws were adopted, and a President, President-elect, Treasurer, Secretary, and Council, were appointed in accordance with the rules for the regulation of district Branches.

The first meeting of council was held February 8th, 1853, when a series of bye-laws was enacted for its guidance. At the same meeting, rules for the regulation of the Branch were revised, and transmitted to the Central Council at Worcester for approval. This consent was obtained, and the rules were then published.

The Metropolitan Counties Branch, immediately on its establishment, began to turn its attention to the relief of the medical profession from some of the disadvantages which seemed peculiarly to oppress it.

On March 1st, a committee was appointed to prepare a petition to Parliament against the unequal pressure of the Income-Tax on medical men. The petition was presented to the House of Commons by Lord Dudley Stuart, after it had received the approval of a special general meeting of the Branch, held on March 16th.

At the same general meeting, a petition to the Houses of Parliament in favour of giving the parliamentary franchise to the University of London, was proposed and adopted.

At a special general meeting, held May 10th, 1853, it was proposed to form a committee to watch the progress of the Medical Reform Bill in Parliament, to communicate with the Medical Reform Committee of the Parent Association, and with other Medical Reform Committees; and to report its proceedings to the Branch. No report has as yet been received from the Committee; but an account of its proceedings appeared in the JOURNAL for June 3rd.

A petition against Lord Lyttelton's Vaccination Extension Bill has also been adopted; and a deputation has been appointed to wait upon the Secretary of State for the Home Department, to request him to refuse his assent and support to any Vaccination Bill, until the profession has been consulted regarding its provisions, and until more information on the subject has been laid before the public.

A petition to Parliament in support of the Lord Advocate's (Moncrieff) Bill, for regulating the admission of professors to the lay chairs in the universities of Scotland, was adopted, and entrusted to Mr. Cowan, the member for Edinburgh, for presentation. The council is glad to perceive that the Bill has passed through the second reading in the House of Commons by a large majority.

The number of members who have paid their subscriptions to the Branch is seventy: but the Council have reason to believe that all, or at least the majority, of the members of the Parent Association, residing within the limits of the Branch, are likely to enrol themselves among its numbers. It does not appear to be generally understood that members of the Association may become members of the Branch, merely by the payment of half-a-crown annually; and this will account for the much smaller number of members belonging to the Branch, as compared with the great number of medical men residing within its limits, who have joined the Association.

From the Treasurer's Report, it will be seen that the expenditure of the Branch has exceeded its income by a small sum. This deficiency has been caused by the heavy expenses for advertisements, postage, circulars, etc., unavoidably connected with its first establishment. These extra disbursements will be entirely avoided in future: and the Council have every reason to expect, not only that the Branch will pay its expenses from the half-crown subscribed by each member, but have a good balance in hand at the next annual meeting.

On the motion of Mr. COLLYNS, seconded by Mr. LORD, the report was unanimously adopted, and ordered to be printed.

THE VACCINATION BILL.

Dr. CORMACK stated (in reply to a question) that he, Dr. Fraser, and Dr. Semple, had not been forgetful of the trust confided to them as a deputation to wait upon the Home Secretary, Lord Palmerston, to remonstrate against any general measure of Vaccination Extension being carried through Parliament, without ample time being afforded to the profession to consider its provisions. Understanding, however, that Sir J. Pakington, who had charge of the Bill in the House of Commons, in deference to the opposition of the medical profession, had agreed not to urge the Bill during this session, they had not as yet fulfilled their mission. In these circumstances, it would have only have been subjecting Lord Palmerston to unnecessary trouble had the deputation waited upon him. They could, of course, still do so, if circumstances emerged which rendered such a step necessary. This was not anticipated; and, indeed, he (Dr. Cormack) might almost venture to congratulate the profession upon obtaining what they wanted—time to deliberate on the Bill of Lord Lyttelton, and the valuable information which had recently been published on the subject of small-pox and vaccination.

GRATUITOUS ADVICE.

Mr. CHARLES moved that a committee be appointed to inquire into the practice of giving gratuitous advice. He said that it was far from his wish to lessen, in the least degree, the liberal and charitable conduct of the profession toward the necessitous poor; but the present "advice gratis" system was so indiscriminate and so extensively adopted in objectionable forms, through every grade of the profession—from top to toe—that inquiry was necessary. The system, he (Mr. Charles) believed to be fraught with many evil consequences, not only to the profession, but to the parties who receive such advice, and to society generally. Instead of being disinterested kindness on the one side, and a grateful boon on the other, it is, in very many instances, a collusion of selfishness and hypocrisy. The question has been prominently taken up by the ASSOCIATION JOURNAL, and it is evidently deeply agitating the profession at the present time. The terms of the motion do not prejudice the question; but if one half of the current rumours be true, an investigation cannot fail to elicit some startling revelations. Mr. Charles then concluded by moving:—

"That a committee be appointed, to inquire into the evils which are said to flow to society and to the medical profession from the practice of giving gratuitous advice indiscriminately and unnecessarily."

Mr. LORD had great pleasure in seconding the motion. There were great evils connected with the present system of club medical relief, benefit societies, and advice gratis at hospitals and dispensaries. It was undoubtedly the duty of the medical profession to be charitable; but it was likewise necessary that the members of the profession should be just to each other. The circumstances which rendered Mr. Proctor's Medical Benevolent College so necessary, might readily be traced to the reckless manner in which unpaid labour was gratuitously given by the profession.

Dr. OGBURN WARD said, that it was very difficult for the young

physician to make himself known in these times, except through the system of gratuitous advice, given either at his own house, or at some hospital or dispensary with which he might become connected. He asked if there was any other way in which a young physician, settling down in a neighbourhood, could make himself known. Through gratuitous cases, he obtains his experience, which may be the basis of introduction to remunerative patients. No young physician can get fees till he be recognised by the public as a man of experience: and how is he to get his experience, except by giving gratuitous advice?

Dr. O'CONNOR, in supporting the resolution, said, that no one could have damaged the position of the young physicians more than Dr. Ogier Ward, by his attempt at a defence of any of their class who resorted to the practices complained of in the resolution. He thought, though he gave his hearty support to the resolution, that to carry it out effectually would be attended with much difficulty. The practices existing at present in London require some check; they are not alone confined to young physicians. We constantly see dispensaries, for special diseases, springing into existence, not to meet the exigencies of the poor, but to bring before the public gaze the name of some individual, whose education, professional or general, does not justify his presumption. He is generally found to be *merely* a member of the College of Surgeons of England, or an honorary fellow under the charter of 1843. Reports of those institutions, whose very existences are so many frauds, are frequently to be seen in the daily papers, and in some of the medical journals. Dr. O'Connor regretted to be compelled to say, that the unprofessional practices complained of in the resolution are not peculiar to young physicians and surgeons. Men of no mean distinction are at the present day, in London, associated with chemists and druggists, in a system of secret formularies, when prescribing for patients, which is disgraceful to the profession; and it is notorious that some who have lately put themselves forward as the champions of the professional morality of the pharmaceutical body—men high in the councils of the Pharmaceutical Society—are parties to such practices. He knew of men who now, to use the words of Mr. Charles, and to adopt them, enter into collusions with chemists, and, though they give advice gratis, receive a per centage on every prescription. It is currently reported, that there is in London at present a Fellow of the College of Physicians, who is the proprietor of a chemist's shop, and who constantly attends there to audit his accounts. It is melancholy to state that, in this metropolis, the system complained of is more common than in the provinces, where the professional character of medical men is far more honourably upheld. He would recommend Dr. Ward's young physician to pursue the toilsome career of the respectable general practitioner, rather than lower his character and that of his profession.

Dr. OGIER WARD explained. He said that he had no wish to oppose the appointment of a committee in terms of the motion of Mr. Charles; for he knew well the great abuses of the advice gratis system. At the same time he had felt that it was right to remember that the question had two sides. He would like Mr. Charles to state how a young physician was to get into practice.

Mr. CHARLES said that it would be for the interests of society and of the profession, if all young physicians would commence as general practitioners. They would then obtain a honourable field in which they could simultaneously gather both fees and experience. There would then be less jostling, and less penury in the profession.

Dr. DAVIES admitted the evils of giving indiscriminate gratuitous advice; but he was doubtful if any abatement of those evils was to be gained by the appointment of the committee.

Dr. BOWMAN mentioned some flagrant violations of professional propriety which had occurred at Dalston, in connexion with the giving of gratis advice by the staff of the German Hospital at that place.

Mr. CARTER mentioned that a gentleman in his neighbourhood, by calling himself a "retired practitioner" and giving "gratis advice," had soon formed a very large connexion. He then gradually made his patients pay, in the first instance upon pretence that the medicines could only be compounded at his own house. At last no one was allowed to leave the house with medicine unless it was paid for; and now he took as much as he could get from those who consulted him. Such cases were very bad; and the other abuses of the gratis system were manifold; but he thought with Dr. Davies that it was hardly to be hoped that the proposed committee could do any good.

Dr. CORMACK doubted very much whether, at the present stage, good would result from a public discussion of special

cases of abuse. He was convinced, however, that if a committee set to work in a conciliatory spirit, some of the enormous evils now prevailing in London from the exercise of a spurious medical philanthropy, might be mitigated. The committee asked for was simply a committee of inquiry: and he therefore hoped that the motion would be carried without opposition.

The PRESIDENT said that it was now his duty to put the question. Before doing so, however, he would wish to say that he hoped it would never be forgotten that our profession is essentially a generous profession; and that, in fact, the physician lies under a moral obligation to give unpaid advice, not merely to the very poorest of the community, but to many gentlemen and gentlewomen of restricted means, such as artists, governesses, and others. He had heard of cases in which some unworthy medical men had treated such persons very harshly, by sending in bills and threatening legal proceedings. The members of the medical profession must not descend to the level of attorneys, who do nothing for nothing. Unless we do much for nothing, we cannot do what is right. (Applause.)

The motion was then put, and carried unanimously.

It was then moved by Mr. CHARLES, and seconded by Mr. TOYNBEE,

That the Committee consist of the following gentlemen:
 Henry Ancell, Esq. Charles F. J. Lord, Esq.
 Thomas Charles, Esq. William O'Connor, M.D.
 John Rose Cormack, M.D. T. Ogier Ward, M.D.
 Patrick Fraser, M.D. George Webster, M.D.;
 with power to add to their number.

CONSTITUTION OF THE COUNCIL OF THE BRANCH.

Some conversation took place regarding the manner in which the members of Council of the Branch should be in future elected. By Rule VII, one-third go out annually, viz., those who have attended the smallest number of meetings. Dr. Davies complained of this as pressing hard on country members, who had twenty or thirty miles to travel to town. Upon the suggestion of the President, Dr. Davies promised to bring the subject before the Council at its next meeting.

VOTE OF THANKS TO THE EDITOR.

Mr. CARTER said that he had a motion to propose, which, though not upon the paper, might be introduced without a long preface. At the annual meeting of the Association, held last year at Oxford, he had strenuously opposed the project of publishing the JOURNAL in London; but he was now ready to admit that the system had worked well, and that the present weekly publication had been commenced and maintained with great energy and ability by Dr. Cormack, who, for his labours, merited the best thanks of this meeting. He (Mr. Carter) had observed that a similar motion had been lost at the annual meeting of the Lancashire and Cheshire Branch, apparently because some members thought that approval of the present implied a censure of the past. He disclaimed any such intention in bringing forward this motion. He admired the manner in which the JOURNAL was now conducted; and he simply asked the meeting to concur with him in expressing its approval. He therefore moved—

"That the best thanks of this meeting be given to Dr. Cormack, for the able and satisfactory manner in which he has discharged the important office of editor of the ASSOCIATION JOURNAL."

Dr. SIBSON had great pleasure in seconding this motion. Perhaps he might be allowed to say, that in some recent numbers he had thought that topics not purely medical had occupied too prominent a position; and that the letters of some correspondents ought to have been pruned by the editor before they were published. As regarded the policy of transferring the JOURNAL to London, he entertained such grave doubts at the Oxford meeting, that he had not then voted. He then felt that they had an excellent journal; and he was not anxious to risk the prosperity of the Association by trying to get a better. In conclusion, he would only say, that he cordially seconded the motion, because he was well satisfied with the JOURNAL, and because he knew that the present editor would truckle to no one, that he was an honourable man, and one who was well qualified to maintain the character of the profession.

Dr. WEBSTER could not give a silent vote in support of Mr. Carter's motion. Upon him, along with a few others, had devolved the great responsibility of selecting an editor; and it was with feelings of the deepest pleasure that he heard from every one with whom he had professional communication, that the manner in which the JOURNAL was conducted gave universal satisfaction. His own opinion coincided with that of an eminent physician, whom he had that day met, viz., that the ASSOCIATION

JOURNAL was not only an excellent medical journal, but the best medical journal. The gentleman to whom he referred had requested to be proposed as a member of the Association, entirely from his admiration of the JOURNAL; and he (Dr. Webster) knew that the vast majority of the four hundred and odd members who had recently joined the Association, had been attracted chiefly by its excellence; and many old members had remained members, who would have resigned, had the Oxford decision not been carried out.

The motion was then put, and carried by acclamation.

The PRESIDENT, addressing Dr. Cormack, said that he had much pleasure in communicating to him the vote which had just been unanimously passed.

Dr. CORMACK said, that the kindness of the meeting had entirely taken him by surprise; and he was therefore not prepared to speak on various topics which the subject naturally suggested. There was one point, however, to which he felt happy in having afforded to him this opportunity of alluding. He knew that it was correct to ascribe much of the present and increasing prosperity of the Association to the great acceptance which the Journal had received from the profession; but then he could not claim more than a fraction of the merit of this result. At Oxford, there had been an anxious contest as to the continuance of the Journal at Worcester, or its removal to London. There was a division of opinion among the best friends of the Association. Many, after the decision, believed and stated, that the chagrin and disappointment of the vanquished party was so great, that they would not co-operate with the other side in supporting the new arrangements, and that they would keep together as a party, that they might ultimately gain the mastery. Now, a very different and a more generous course of action had been adopted. When it was seen that the Journal Committee was really empowered to make the changes which it had made, a cordial union was speedily established among all parties; and, indeed, the very dread of disruption had become a prolific source of strength, as it had roused the energies of all the true friends of the Association. The present prosperity was, therefore, mainly due to this noble and generous conduct; and it was by it that he (Dr. C.) had been placed in so peculiarly advantageous a position—a better position than any of his predecessors had ever enjoyed. To the kindness, courtesy, and confidence which had been bestowed upon him by Sir Charles Hastings, the President of the Council, and Mr. Sheppard, the General Secretary, he owed much; and he was quite sure that there was no man more delighted at the success of the Journal than Sir Charles Hastings, whose conduct in this, as in all other Association affairs, was simply regulated by a desire to promote the good of the profession. (Applause.) Sincerely thanking the meeting for the vote of encouragement and confidence which they had passed, Dr. Cormack concluded by saying that he hoped, by industry and integrity, to continue to merit their approbation.

VOTES OF THANKS TO THE OFFICERS.

It was proposed by Dr. DAVIES, seconded by Dr. BOWMAN, and unanimously carried—

"That the thanks of the meeting be given to the President, President elect, Treasurer, Secretary, and Council, for their labours since the establishment of the Branch."

It being now past six o'clock, the meeting adjourned.

THE DINNER.

The party reassembled at half-past six o'clock, in the large dining-room of the Brunswick Hotel, which so pleasantly looks down upon one of the most interesting and ever varying scenes of the busy Thames. The entertainment, both for body and mind, was excellent; and all seemed to feel that such festive occasions ought to be looked upon as contributing in a very important degree to promote the brotherly communion, unity, and usefulness of the profession. The President, Dr. FORBES, occupied the chair; and the President-elect, JOHN PROPERT, Esq., officiated as vice-chairman.

After the cloth was removed, the following toasts were given in succession:—

1. "The Queen", by the Chairman; who, after passing a high eulogy on Her Majesty, said that she had a peculiar claim at present upon doctors, as she was a patient, having measles. This toast was most loyally responded to; and the company, upstanding, sang "God save the Queen", the lead being very effectively taken by Dr. Ogier Ward.

2. "The Prince Albert, the Prince of Wales, and the Royal Princes and Princesses", by the Chairman. After the toast had been drunk, the Chairman having asked if any one would give

an appropriate song, Mr. Collins volunteered, and sang some verses in honour of the Royal family, composed by himself.

3. The Chairman next gave "The Provincial Medical and Surgical Association—continued and increased prosperity to it; and with it the health of Sir Charles Hastings", whom to name is to praise, a true, honest, and good man, whose single minded ambition is to benefit the profession. (Loud applause.) This toast was drunk with three times three, upstanding.

4. "The Metropolitan Counties Branch of the Provincial Medical and Surgical Association"; which, though not yet one year old, is already a strong and flourishing member of the parent trunk.

5. Mr. PROPERT, the Vice-chairman, proposed the health of "The President", in a very eloquent speech, which was received with great applause. Dr. FORBES, in returning thanks, said that, although he felt that he was not now the man he had been, and although old age had caught him in its clutch, he trusted he might yet have strength left for some time to come, to co-operate with his friends in promoting the great objects of the Association.

"The Fine Old English Gentleman" was then sung by Mr. Carter of Hadley.

6. Dr. WEBSTER, of Dulwich, gave "John Propert, Esq., the President-elect". He expatiated upon the philanthropic and successful exertions of Mr. Propert in the cause of the Medical Benevolent College. It was indeed wonderful to contemplate what Mr. Propert had achieved. It would be remarkable under any circumstances; but when it was known that Mr. Propert was immersed in one of the largest London practices, the results which he had obtained were truly astonishing. The name of John Propert would go down to future generations, inseparably connected with the history of the medical profession.

7. "The Irish Medical Association and its President", by the CHAIRMAN.

8. "The Honorary Secretary, the Treasurer, and the Council", by Mr. COLLYNS. Dr. Ogier Ward and Mr. Toynbee returned thanks.

9. "Dr. Cormack, the Editor of the Association Journal", by Mr. HUNT. Dr. Cormack returned thanks.

The CHAIRMAN then gave "Good Night"; and the party broke up about 10 o'clock.

EDITOR'S LETTER BOX.

THE ALLIANCE BETWEEN RELIGION AND MEDICINE.

LETTER TO THE EDITOR FROM ΠΡΕΣΒΥΤΕΡΟΣ.

SIR,—I have before me the numbers of the ASSOCIATION MEDICAL JOURNAL for the present year. I have carefully perused these numbers as they issued from the press; and I am anxious to bear my testimony that they contain an efficient supply of valuable practical information, and a powerful advocacy of the rights and privileges of the medical practitioner.

I am now an ex-member of the practising body of medical men, in the ordinary meaning of the term, having been for a few years past engaged in a profession of a still more sacred kind; and it may not be conceded to me to judge of practical matters in medicine. But, having spent twenty-seven of the best years of my life in medicine, and taking as warm an interest now as I ever did in watching and relieving the sufferings of those around me, who cannot pay for a doctor, may I not still be allowed an opinion in matters of this kind? It shall, however, be expressed at present in very few words. I feel, then, the greatest possible satisfaction in giving it as my humble conclusion, that the practical department of the Journal has become more valuable, and I heartily concur in what may be called the spirit of the statements made at the recent Branch meetings, that if members continue to support you as they have hitherto done, we shall have a treasury of knowledge of the greatest value.

But my great object at present, is to bear my humble testimony to the bold, energetic way in which you have advocated the rights and privileges, while you have not sought to hide the responsibilities of your noble profession. In the cause of Medical Reform, you have been vigilant in keeping before the Association the necessity of action at the proper periods; and this assisted to keep alive, I trust, that *esprit de corps* which is necessary, and which is indeed alone able to secure this all important object. May the flame thus excited not be quenched till quackery, with its innumerable evils, be finally rooted out.

To me, it has always been a painful subject; and, when so placed that it cannot be said I am interested peculiarly (for I have often had it rung in my ears that "the doctors fear quackery, lest their own gains should suffer from it"), I can venture to assure you, that the *expression* of my honest indignation daily increases, when I see how my parishioners and others are deluded by quacks. That which has always been to me a source of disquiet, is the little hope that the mass of people can ever be sufficiently well informed on those points, a knowledge of which is necessary to enable them to judge of the *dangers* of quackery, and of the inestimable value of scientific practice. My feelings have been put to the most painful trial, again and again, when, going my rounds as a spiritual adviser of those committed to my charge, I have seen persons committing their lives unreservedly to the uneducated charlatan. Would that the members generally of the sacred profession, to which I now more particularly belong, had the means of acquiring a sufficient amount of anatomical and physiological knowledge, to enable them to discern what constitutes sound medical treatment; and then there would be no necessity for your bringing any of them before the public as abettors of any species of quackery. I was in the company of an aged clergyman and two or three ladies, a very short time ago. One of the latter spoke in favour of "homeopathy", not knowing that I was an M.D. I proceeded to dispute the accuracy of her statements, when, to my surprise, my clerical friend rushed to her aid! He is, perhaps, better informed in divinity and literature than most of the clergy, and is a good specimen, therefore, of his profession; but he is totally ignorant of the theory of medicine, and consequently of its right practice. I mention this case, to show you that it is absolutely necessary, either to educate gentlemen in the science of medicine, to a certain extent, or to enact laws to protect them from the quack. The latter might readily be done: the former, only to a very partial extent, I fear. If the population at large of this country could but for one moment see into the depths of danger, on the one hand, from quackery, and of safety, on the other, from educated practice, what a rush there would be made to petition to Parliament for a "Medical Reform Bill". Lord Palmerston would then have no difficulty in his way, save one, and that would be to get their earnest cravings sufficiently soon satisfied. Go on then, sir, in your denunciations of quackery; and my earnest wish is, that the medical men of the provinces may rally round you, and show to the world that our Association is in earnest, and that the cause it has in hand is not individual, but general,—is not only worldly, but also heavenly in its tendencies; and that, while they desire for themselves and their families an honest livelihood, and a respectable position in this world, their grand aim and end is the relief of their fellow men from pain and suffering of body and mind.

Thus far have we *implied* the dangers that follow to the body from ignorant practice, but there is a moral evil which we cannot any longer with safety overlook. I mean that resulting from quack advertisements. You have brought this matter forward in a manner that cannot be gainsaid, in the number for 17th June, and I hope these and other papers may do much good in drawing special attention to this most glaring evil. You do not allude to the fact that a society has been formed for the suppression of "vicious advertisements". Last year, I laid hold of a tract (which I now enclose), published by an union established for this purpose.* If it still exist, it should certainly be aided by medical men and clergymen, and indeed, by all right minded persons.

I admire the Christian spirit with which you embue your remarks. Be assured the time has gone past when medical men shall hesitate to mix up with their godlike profession a Christian confession. Glad am I to know (although I never favoured the too prevalent notion that they were, as a body, contemptuous on the point) that there are vast numbers of "good men and true" in the medical profession who "earnestly contend for the faith once delivered to the saints", and that they are not ashamed to acknowledge Him who set them the noble example of going about doing good. The petition to Parliament against the opening of the Crystal Palace on Sunday, by so many medical men, speaks loudly in favour of my opinion. The letter in opposition to this movement, in the number for 1st July, you have convincingly combated.

It is a very easy matter, for any one who chooses, to say: "You cannot get the people who would visit the Crystal Palace to go to church, and they had better be at the former than in a worse place." To deny the latter clause of this assertion, would be simply absurd. But, I would just ask this simple question:

* This Society may now be revived.—EDITOR.

"Is it not our business *rather* to devise means to induce people to serve God, than to indulge their senses?" To say that because people won't go to church, we are to prepare places of amusement for them on Sunday, is, indeed, a palpable absurdity on the part of a Christian—nay, may I not say, a positive act of sin. If we cannot lead them to the house of God, shall we set up a "temple of pleasure" in opposition to it? The spirit that actuates man in this direction, benevolent though it be, has *caused*, and, I fear, will *cause*, much evil. Moreover, it cannot be insured to us that *the mass* who indulge in vicious habits on Sunday will go to the Crystal Palace, if it were open to them. On the contrary, they are the persons who could not afford to do so. This sinful indulgence must be paid for, and would be the privilege of those who could do so, and would lead to the desecration of the Lord's Day to a fearful extent, and, as you justly observe, be the means of bringing upon a *certain* class *extra* toil. In a word, it would become a national and individual sin, the consequences of which would be incalculable.

But, to conclude a letter, which some may perhaps call a "sermon", already too long. A love for *scientific medicine* induced me to continue a member of the Association after I had entered the sacred office which I now occupy; and it gladdens my heart to find, that my wish to continue a *faithful alliance* between divinity and medicine, was not setting up a false theory, for it is daily shown to me that medical men are now more strongly inclined than ever, to consider them "compatibles"; and as it was meat and drink to Him, in whom is all our hope of good, for time and eternity, to join bodily with spiritual relief, so are we content to do His will. In letter No. 4, in the last number of the JOURNAL, on this Sabbath question, I read the workings of the heart and mind of a man, at whose feet I should feel it an honour to sit and learn wisdom. He evidently feels his advocacy is on the right side of the question.

I trust, sir, none of my medical brethren will set down this expression of my feelings as a piece of clerical "cant" so called, for I have not the slightest disposition to indulge in it. The *educated, manly, straightforward, honest hearted, humble minded*, Christian is the person I admire; and I would always endeavour to work through the *understanding* as well as the heart, in engaging my people to follow in the steps of Him who "is the way, the truth, and the life". I am, etc.,

Peter Burgess, M.D.

July 18th, 1853.

[We are again obliged to defer the letters which were in type last week; they shall soon appear, together with the Petitions on the Sunday Question from Edinburgh, and from the Macclesfield Medico-Ethical Association. Many letters on Anæsthesia in Parturition, on Life Insurance Companies, and other topics of interest, have been received.]

NEWS AND TOPICS OF THE DAY.

THE AZTECS IN LONDON.

The *Times* has created an extraordinary interest in two children, now exhibiting in London under the name of Aztecs; but which, according to Mr. Owen's statements at the Ethnological Society, are more probably the dwarfed offspring of a cross between the Spanish inhabitants of Mexico, and a mongrel breed containing a slight admixture of Indian blood. Premising that we incline to the theory of Professor Owen, we subjoin the greater part of the circumstantial statement on the other side which was published by the *Times*. It is eminently calculated to captivate the wonder loving multitude, and to make the Aztecs a lucrative speculation.

"The scientific public has lately been much interested by the arrival of two children, of a race hitherto strange to London, from a mysterious region of Central America. That they were introduced to the Queen on Monday last is one of the facts of the *Court Circular*.

"Professor Anderson, by whom the children are accompanied, has arrived at the conclusion that the boy is 17 years of age and the girl 11.

"The boy is the type of the pair. His forehead is retreating; and this, with the size of his nose, which is strongly marked aquiline, gives the face a birdlike appearance. The upper jaw projects, while the lower jaw recedes, so that when the mouth is closed the under teeth do not touch the upper, but approach the middle of the palate. The countenance produced by this

strange combination of features is at the first glance idiotic, but the impression of idiocy is soon removed by the bright intelligence which sparkles in the large eyes, and by a restless curiosity, which is visible in every gesture of the little creatures.

"The sight of a new type of humanity only three feet high, without the deformities of ordinary dwarfs, is of itself highly curious; but these children are rendered still more remarkable by an historical theory which is connected with them. The region whence they are brought is said to have been the place of refuge chosen by the Aztecs when driven from Mexico by the conquering sword of Cortes, and it is supposed that they are among the last surviving relics of that ill-starred race, with whom we have recently been made familiar by the researches of Mr. Prescott and Mr. Stevens. The children bear the strongest resemblance to sculptured figures unquestionably of Aztec origin; and on one occasion, when an ancient Mexican idol was brought to them, they recognised it, and embraced it at once. It seems that while they were at New York (where they created a great sensation) this idol was accidentally broken, and that the boy burst into an agony of grief at the calamity. The smallness of the children's stature is accounted for by a well known cause of degeneracy—namely, a prohibition against marriage with strangers or members of an inferior caste. It is to the sacerdotal caste, which would rank like that of the Brahmins in India, that the children are assigned; and so rare have the individuals of this race become, that it is said they have been advanced from the position of priests to that of gods—no very difficult advance under a system of theocracy. The fact that when the children sit down they fall into a posture which is general among Mexican idols, and which would be extremely difficult if it were not the result of early training, is in favour of this supposition.

"Having given the chief particulars of internal evidence that the children are really Aztecs, we now subjoin the external evidence in the shape of a statement furnished by the exhibitors:—

"In 1848 Mr. Huertis, of Baltimore, and Mr. Hammond, of Canada, attempted to explore Central America. They had read Stevens's account in his *Central America* of a conversation between himself and a priest residing at Santa Cruz del Quiche, relative to an unexplored city on the other side of the Great Sierra range, the glittering domes and minarets of which the priest averred having seen from the summit of the Sierra. The people, manners, and customs of this city were supposed to be precisely the same as in the days of Montezuma. Messrs. Huertis and Hammond arrived at Belize in the autumn of 1848, and, turning south-west, arrived at Coban on Christmas Day. They were there joined by Pedro Velasquez of San Salvador, a Spaniard. From Coban they proceeded in search of the mysterious city. From Velasquez alone is any account of their travels to be obtained. Huertis and Hammond have never returned to tell their tale. According to the statement of Velasquez, on the 19th of May they reached the summit of the Sierra, at an altitude of 9,500 feet in lat. 15° 48' N., and beheld in the distance the domes and minarets of a large city, apparently of an Egyptian character, and about 25 leagues from Ocosingo, in the same latitude, and in the direct course of the River Usumacinta. This city they eventually reached. Velasquez describes it to be of vast proportions, with heavy walls and battlements, full of temples, gigantic statues, and pagan paraphernalia; the people having Peruvian manners combined with Assyrian magnificence, and bound to remain within the walls, seeking no intercourse with the world around. The name of the city is Iximaya. The travellers were informed that white men had previously entered it, but that no white man had ever returned. Hammond and Huertis were both slain—the former in entering the city, the latter in endeavouring to make his escape.

"Velasquez being more wary, lulled his captors into security, and not only escaped himself, but brought with him two children belonging to the priests—the two now in England."

THE ABORTION CASE, to which we referred at p. 410 of the number for May 13th, was tried on Wednesday, 6th July. Cunningham, the principal party implicated, was convicted and sentenced to fifteen years transportation. In the indictment he was designated "a surgeon"; but so far as we can learn he had no right to be so described. In the present state of the law, it appears that any miscreant may with impunity assume a medical or surgical title as a cloak for iniquitous practices.

APPOINTMENTS.

[*An asterisk is prefixed to the names of Members of the Association.]

- GIBBON, Septimus, M.D., elected Assistant-Physician to the London Hospital.
GUTHRIE, G. J., Esq., F.R.S., elected Vice-President of the Royal College of Surgeons of England.
*HALLEY, Alexander, M.D., elected Physician to the Blenheim Street Dispensary.
LAWRENCE, William, Esq., F.R.S., elected Vice-President of the Royal College of Surgeons.
LUKE, James, Esq., Surgeon to the London Hospital, elected President of the Royal College of Surgeons.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were Members of the Association.]

- DEARNS, R. P., Esq., Staff Assistant Surgeon of Her Majesty's Forces, at Antigua, of yellow fever, aged 27, in June last.
FORBES, William D., Esq., Surgeon, at Comrie, Perthshire, on June 28th.
GREEN, Henry, Esq., Surgeon, at the Oven Diggings, Melbourne, South Australia, aged 44, lately.
JERROLD, Thomas, M.D., at Greenhill Street, Manchester, aged 84, on June 24th.
LANE, J. HUNTER, M.D., of Brook Street, Grosvenor Square, at Brighton, on June 23rd. Dr. Lane was for some years a practitioner in Liverpool and Lancaster; and the author of many works on medical science.
O'FLAHERTY, Dennis, M.D., at Croom, County Limerick, Ireland, on June 20th.
*OUTLAW, A. M., Esq., Surgeon, at Wellesborough, Northamptonshire, aged 87, on June 4th.
WAINHOUSE, Alfred, Esq., Surgeon, at Halifax, on June 29.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XXX.

LONDON: FRIDAY EVENING, JULY 29, 1853.

NEW SERIES.

GENTLEMEN WISHING TO JOIN THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION ARE REQUESTED TO APPLY TO THE GENERAL SECRETARY, TO THE BRANCH SECRETARIES, OR TO THE EDITOR OF THE JOURNAL. The Annual Subscription is One Guinea. The Subscription runs from January to January; and members now joining will receive the Numbers of the JOURNAL from the commencement of the year. Members receive the JOURNAL free by post.

IRREGULAR DISTRIBUTION OF THE FEES OF PAROCHIAL MEDICAL OFFICERS.

A LETTER from Dr. PHILPOT BROOKES, which in February last appeared in the *Cheltenham Examiner*, on the subject of the fees of medical officers, lies now before us. It reminds us that an important fact ought to have been stated in our last week's leader on poor-law medical relief, viz., that the beggarly salaries which the law allows for medical attendance on the sick poor are distributed so irregularly, that the hardest worked practitioner is not uncommonly the worst remunerated.

Dr. Brookes's letter was written to the "Medical Committee of the Board of Guardians of the Cheltenham Union". Some complaints had been lodged against him by the Rev. C. B. TYRE, and he wrote to prove that they were utterly unfounded.

It seems that the number of cases that come annually under the care of Dr. Brookes are 856, amongst which are included several serious surgical cases. To these also may be added numerous others not returned in the weekly medical book. His own statement is: "I have upwards of 1,000 new cases yearly, and generally from eight to ten patients daily."

It will thus appear—our calculations of last week being remembered—that Dr. Brookes performs at least four times the average amount of parochial service, and he ought therefore, in common fairness, to receive four times the amount of salary, or £332 per annum. We do not know what the amount of Dr. Brookes's salary may be. That it does not reach the sum we name, we are fully convinced; and if it did, the miserable meanness of the poor-law authorities would stand out just as prominently as ever, inasmuch as Dr. Brookes either reduces the average sum of £83, which, as before stated, falls to the 3,233 parochial medical officers of this country, by receiving himself an unusual sum, or he suffers three or four times the penalty by receiving an amount that approaches only to the average share.

Dr. Brookes's case is not an exceptional one. We are acquainted with several instances in which a union practitioner, with six and eight hundred patients annually, receives no more pay than another with half that number. Still more painful is it to know the fact, that the extent of an union district scarcely affects the salary in an appreciable degree. Far down in the country, an union district often extends over many miles of dreary, dirty, broken

country, where no chaise can travel. On horseback, early in the morning, starts out the medical officer, and except that he has a saddle, that he dismounts occasionally, and that he possesses generally a *tame* horse, he is for the day as close an equestrian prisoner as was Mazeppa.

In the neighbourhood of London, on the contrary, the district practitioner has his patients very near to his own door; his travelling is attended with few difficulties, his time is saved, and his surgery necessities are obtained from town with little trouble or expense.

Still, as we said before, the two officers thus dissimilarly situated receive salaries exceedingly similar; nay, in some instances, that of the country practitioner is less than that of the suburban, or metropolitan. Nor is there any probability that this state of matters will end, until the Government removes the power of affording medical relief to the poor from boards of guardians, who, in all cases, purchase the services of the medical man on the same miserly scale as they purchase from the hay and corn dealer the constituents of that water gruel, with which they drench the miserable inmates of their gaol asylums.

In making these remarks, we wish particularly to state that it is no object of ours to draw painful distinctions betwixt the services and rewards of parochial medical officers. It is our object to benefit the whole class of parish doctors, than whom, no men more worthily deserve to be benefited. To equalize the wretched pittance at present given for their services would be impossible, since the endeavour to subtract from the salary of the best paid, would be well nigh equivalent to "taking the breeks off a Highlander".

THE MEDICAL SOCIETY OF LONDON AND THE SCIENCE OF PHYSIOLOGY.

SOME months since, on the 18th of February, we informed our readers that the Council of the Medical Society of London was projecting the establishment of a section, or sectional committee, for the cultivation of physiological science. We have now the gratification of stating that the project is in a great degree realised; that an active physiological committee has been elected; that this committee is open to receive papers written or communicated by any fellow of the Society; and that special evenings are to be appointed for the reading and discussion of such papers as may be approved of by the committee.

Few members of the profession will fail to approve of this movement of the London Medical Society. It was every day becoming more and more obvious that a physiological society in London was absolutely required; while side by side with this feeling, existed another, viz., that separate medical societies were already so numerous, that to belong to all of them, and to pay a yearly subscription to each, gave rise to an expense which many earnest scientific men were not able to meet without great self sacrifice. It was

also pretty well understood that such an expense was quite unnecessary; that it was simply absurd to allow a set of rooms to be filled one night in the week with a scientific throng, and to be allowed to remain dark and vacant all the other nights; and that it would be possible for one of the old and distinguished scientific societies to make the excellent precedent of establishing within itself a section, which should, at one and the same time, encourage the prosecution of an important special science, lessen the demands on the purse (often not the richest) of the truly scientific man, and add additional lustre to the parent body.

This precedent the Medical Society of London has established; and, with heart and soul, we wish the project every success. Moreover, we have every reason to believe that the experiment must be successful. The Fellows of the Society, with a few exceptions, have, as far as we can learn, entered warmly into it; the committee have already received promise of sufficient papers for the next session; and many physiologists, who have no connexion whatever with the Society, have expressed to us the interest they take in a movement so well calculated to lead to important results.

So long as the Physiological Committee of the Medical Society of London continues to carry out its functions in a spirit of earnest devotion to the advancement of science, it will be our desire to render to it all the support we are able to give.

PROPOSED SOCIETY FOR THE SUPPRESSION OF FRAUDULENT AND OBSCENE ADVERTISEMENTS.

THE organization of this Society proceeds favourably. Gentlemen who desire to become members are requested to communicate with Dr. Cormack, Putney, who has consented to act for a short time as Honorary Secretary. A list of the Provisional Committee will be published about the 1st of September, when the period of the first meeting of the Society will likewise be intimated.

We rejoice to find that we are certain to have some warm allies among the better class of newspapers. The *Scottish Guardian*, a Glasgow newspaper of very large circulation, thus refers to our labours.

"The ASSOCIATION MEDICAL JOURNAL which has done good service to the Sabbath cause, as our readers have lately seen, has commenced a vigorous attack upon the publishers of quack advertisements. Warmly approving of the views of this excellent periodical, we give a place to them in the first page, and recommend them to the serious attention not only of the publishers of quack advertisements, but of the heads of families who receive this pollution into their households."

THE HISTORY OF THE ROYAL MEDICAL SOCIETY OF EDINBURGH TEACHES A LESSON TO OUR ASSOCIATION.

THE Royal Medical Society of Edinburgh is one of the most interesting, and one of the most useful medical institutions of this country. From the circumstance of its being a student's society, it necessarily experiences many vicissitudes, both in the number and the vigour of its members; but, nevertheless, at the end of one hundred and sixteen years,

it is truthfully declared to be in as palmy and prosperous a condition as it ever enjoyed. It has lately yielded to the pressure of migratory reform, and removed from Surgeon's Square, to a splendid new Hall in a modern and more favoured quarter. Alluding to this change, Dr. W. M. Dobie, the senior annual President, said in his valedictory address, recently printed at the expense of the Society:

"Gentlemen, I am sure you will agree with me in thinking that we have now brought to a conclusion one of the most remarkable and eventful sessions which it has been the lot of our Society to complete, during the whole period of its long and illustrious career. If we may be allowed to judge by the testimony of the older members, the Medical Society has now attained an eminence, equal to that of any period in its past history."

We must quote another extract from Dr. Dobie's address, because we think that it conveys a lesson to our own institution, which ought not to be neglected. It shows that a well nursed *reserved fund* forms the best hope of prosperity and perpetuity; and it painfully reminds the members of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION that they have no such source of reliance.

"The easy transition we have made from the murky region of Surgeon's Square to this commodious building, makes one almost ready to fancy that some magic has been, in this instance, at work, and that, like an Aladdin's palace, our Hall has risen up by enchantment. But I would now remind you, gentlemen, that the case is far otherwise; these splendid results are the effects and fruits of the well directed labours, and the self-sacrificing liberality, of those who have immediately gone before you. Through the careful economy of our predecessors, and more especially from the prudent management of the finances of the Society by our esteemed Treasurer, Mr. Macfarlan, the Society has been able to lay aside a sum of money, which has gradually accumulated to £1,300. In the year 1850, when the members of this Society resolved to accept the offer of purchase of the Hall in Surgeon's Square, made by the managers of the Royal Infirmary, the Society reluctantly agreed to sacrifice, if necessary, a portion of this fund to assist in the building of a new Hall. But, that this encroachment on a sum that has more than once rescued the Society from destruction, might not be required, every attending member came forward in the most liberal manner to procure advantages, not to be enjoyed by themselves, but by you,—their successors."

Mark the words—and we know them to be true—"The reserve fund has more than once saved the Society from destruction." Now our Association has, it is true, no buildings and no library to maintain; but it has great expenses to meet, which cannot well be curtailed, and which perhaps ought to be increased. At present, all may be *couleur de rose*, and it may not be difficult to keep our expenditure within our income: yet evil days may come upon us; our best men may die, or become unpopular; and then, with funds enfeebled by resignations, where would the ASSOCIATION be, without the temporary aid of a reserve fund? In great difficulty and peril, we hesitate not to reply. In this, then, the time of our prosperity, let this momentous question of a reserve fund be fairly considered; and, if it be patiently and profoundly examined, we have no fears as to the result. Ere another anniversary come round, we trust that a good scheme for a reserve fund may be matured; and that perhaps even a nucleus may be formed by the donations of the generous and wealthy.

ORIGINAL COMMUNICATIONS.

INVERSION OF THE UTERUS AFTER PARTURITION, FATAL IN SIXTEEN WEEKS; WITH REMARKS.

By F. W. MACKENZIE, M.D.Lond., Physician to the Paddington Free Dispensary for Diseases of Women and Children.

FRANCES GRIFFITHS, aged 26, married three years, of short stature, but well proportioned, was admitted into the Paddington Infirmary, December 15th, 1852. She was suffering from anæmia in an intense degree. From her history, it appeared that it had followed a confinement, which had taken place rather more than two months previous to her admission. This had been attended by an unusual amount of hæmorrhage, which had frequently recurred subsequently; and her husband being out of work, she had since been in a very destitute state, and obliged to undergo much physical fatigue. On admission, the hæmorrhage had ceased; and, as she neither complained of any uterine symptoms, nor stated anything which led to a suspicion that any particular lesion had occurred during labour, no immediate examination of the uterus was made. She was ordered to be kept perfectly quiet in the recumbent position, and to have a light nutritive diet; and the mineral acids were prescribed, with occasional mild aperients. For three weeks, she continued progressively to improve, scarcely any hæmorrhage occurring during this period. She gained strength and colour; and the only alteration made in the treatment consisted in the addition to each dose of the mineral acids of ten minims, increased to fifteen, of the muriated tincture of iron.

Her favourable progress continued until January 4th, 1853, when menstruation began. This commenced normally, without pain, and without being excessive; but, in anticipation of its becoming profuse, she was ordered to take gallic acid in five grain doses every four hours. Everything went on favourably until the 6th, when a profuse and unexpected loss of blood took place.

In my absence, she was seen by Mr. Norway, who, finding her blanched and nearly pulseless, ordered her stimulants, and directed the dose of gallic acid to be increased from five to ten grains. In the course of the day, she had somewhat rallied; and, on visiting her, I directed the same treatment to be continued, with some unimportant additions. The next day, the hæmorrhage had considerably lessened. On the 19th, it returned, and several large coagula passed. After this, it again lessened, and on the 22nd she was removed to the lying-in ward, where an examination of the uterus was made.

On introducing the finger into the vagina, a somewhat elongated pyriform tumour was found to occupy the upper part of this organ. It was about the size of an egg, was firm and somewhat elastic to the touch, and its surface had a fine velvety character. On tracing it upwards, it became somewhat narrower, and was at length felt to be embraced by the uterus, which completely encircled it. Inferiorly, its transverse diameter might be about an inch and a half; superiorly, it was somewhat less. It was smaller in its antero-posterior than in its transverse diameter, and in length might be about two inches. On pressing it with the pulp of the finger, the patient stated that she felt no particular pain; and, as far as could be judged from repeated trials, the tumour was not very sensible to this kind of pressure. On introducing a speculum very cautiously, the surface of the tumour was found to be covered with a layer of coagulated blood, which gave it a dark purplish appearance. On wiping this away, a convex body was brought into view, of a pale red or salmon colour, and, on touching it with the blunt end of a probe, pain was distinctly felt; whilst, from the several points of the tumour touched, fine capillary streams of blood poured forth. There could thus be no doubt that the tumour was an inverted

uterus; and, on inquiring more particularly into the history of the case, the following particulars were elicited.

The patient had been married nearly three years, and had given birth to two children. The first was born on the 11th of February, 1851, about ten months after marriage; the second, on the 11th of October, 1852. The first labour was long and difficult; and the child, though born alive, died two days afterwards. The placenta was retained, and had to be separated manually from the uterus. She, however, did well, and recovered without any unfavourable symptom. Menstruation returned in due course, and she neither experienced any uterine pain nor leucorrhœa subsequently to this labour. In the beginning of January 1852, she again became pregnant, and went the full period of gestation without any unfavourable symptom. She was confined on the 11th of December, 1852. The labour was easy and expeditious, as far as the birth of the child was concerned. With regard to the placenta, the gentleman who attended her informs me that, in this labour, it was not adherent, and that it came away at the usual time, by simply pulling moderately, and without any force, upon the cord. After its removal, he made an examination of the uterus, and felt something protruding into the vagina, which he suspected to be an inverted uterus. He accordingly made several attempts to replace it, and after a time was led to believe that he had succeeded in doing so. These attempts, however, the patient appears to have considered to have been made for the purpose of removing the placenta; for she stated that it was adherent; that, half an hour after the birth of the child, an attempt was made to remove it, which failed; and that it was not brought away until an hour and a half after the child had been born. Soon after its supposed removal, she stated that she experienced, in the uterus, intense pain of a burning character, which was attended with profuse hæmorrhage. The pain was so severe, that it occasioned her to be delirious; and, although it was somewhat allayed by the remedies employed, it nevertheless continued for three days, with occasional intermissions, in a very severe form. The day after her confinement, she was visited by her medical attendant and another practitioner; and the latter attempted, she stated, some manipulations, but failed to give any relief. Matters thus continued for five days longer, when another consultation was held upon her case, and a third medical man attempted, but unsuccessfully, the reduction of the uterus. From this time, she continued to suffer more or less from uterine hæmorrhage for some weeks, and her stomach became so irritable, that she could scarcely retain any food. Under the treatment adopted, however, she eventually improved; and, as previously stated, on her admission into the infirmary, the hæmorrhage had ceased.

From the 22nd to the 27th of January, there was scarcely any return of hæmorrhage. The bowels had been regulated by castor oil; but, on account of the irritability of stomach, and the expressed wish of the patient, no other medicine was given. Her diet was light and nutritive, and she was allowed 6 oz. of port wine daily.

On the night of the 26th, she was seized with faintness, and profuse hæmorrhage again took place. This was attributed by the nurse to her having fretted about her child, who had been attacked with whooping-cough the preceding day. Gallic acid was again ordered in ten grain doses every four hours; and pledgets of lint, soaked in alum water, were applied to the uterus. As, however, it became evident that these hæmorrhages could not be prevented, and as it was equally certain that she would sink under their continuance, I determined to take steps for the removal of the inverted portion of the uterus.

On the 28th, the hæmorrhage had almost entirely ceased, and she was visited by Mr. Marshall, to whom I had communicated my intention of removing the inverted portion of the uterus by the electric cautery. He thought favourably of the operation, and I accordingly gave directions for the preparation of the necessary apparatus. In the mean time, the gallic acid was ordered to be continued, as well as the application of the solution of alum to the fundus uteri.

The propriety of attempting the forcible reduction of the uterus under chloroform was considered on this and other occasions: but it was abandoned, on the grounds, 1, that attempts had already been made at an earlier and consequently more favourable period, and had failed; 2, that the attempt had almost always been unsuccessful, when made at such a late period after the accident; and 3, that, if it were attempted without success, considerable injury might be done the patient in her then exhausted condition. I was not then aware that reduction had been effected under chloroform at an equally late period, or the attempt would certainly have been made.

January 29th. No particular hæmorrhage had occurred; but a large quantity of serous fluid was passing from the vagina; the countenance was extremely exsanguine, and the bowels were flatulent and confined. The patient was directed to take twenty drops of oleum terebinthinæ every four hours, in addition to the gallic acid.

January 30th. She was still suffering from a profuse serous discharge, and was excessively weak and anæmic. The face was swollen and cedematous, especially under the eyes, and she felt a disinclination to take food. The turpentine was not given on account of her excessive objection to it. She was ordered to have four ounces of brandy daily, in addition to six ounces of port wine, three eggs, beef-tea, and arrow-root. The gallic acid was continued; and, if restless or sleepless at night, she was to take ten drops of laudanum every half-hour, until sleep or quietude were obtained.

January 31st. She had passed a comfortable night, and felt somewhat better, although no opiate was given. There had been scarcely any hæmorrhage; and the serous discharge

from the vagina had very much lessened. Twenty drops of dilute nitro-muriatic acid were now ordered to be taken in water with each dose of the gallic acid.

February 1st. No hæmorrhage had yet returned; but a serous fluid still passed from the vagina. She was extremely prostrate and exsanguine; and her stomach was so irritable that she could with difficulty retain the gallic acid pills. They were accordingly discontinued, and she was directed to take the dilute nitro-muriatic acid alone in water, with an opiate at night if restless.

February 3rd. There had been no return of hæmorrhage; and the colourless discharge was now very slight; but the expression of the patient was one of extreme prostration, and her breathing was laboured and at times difficult. Her stomach was now so irritable, that she took food with reluctance. She was ordered to continue the dilute nitro-muriatic acid in water, and to take with each dose ten minims of tincture of opium. The symptoms of exhaustion continued to increase throughout the day, and she died at half-past eleven, P.M.

POST MORTEM EXAMINATION, made on 5th February. No abnormal appearances were met with, beyond those connected with the uterus, and the exsanguine state of the system to which it had given rise. The condition of the uterus is well shown in the accompanying woodcut, and therefore little need be added in explanation. It will be seen to be in a state of partial inversion. The relations of the fundus uteri to the cervix and vagina, and the entrance of the round ligaments and Fallopian tubes into the peritoneal *cul de sac* of the fundus are very clearly shown, as well as the form, size, and general characters of the inverted portion of the uterus.

A. Fundus uteri.
B. Cervix uteri.

C. Vagina.
D. D. Round ligaments.

E. Fallopian tubes.
F. F. Ovaries.

REMARKS. In reviewing the circumstances of this melancholy case, I will confine myself to a brief consideration of some of the more practical questions which arise in connexion with the causes, consequences, and treatment of inversion of the uterus.

CAUSES. At the present day, a difference of opinion appears to exist as to the nature of the causes which give rise to this displacement, in connexion with parturition. By some writers it is regarded as the consequence of improper mechanical interference or traction upon the cord; whilst by others it is supposed to occur independently of any such causes, and to be the consequence solely of a preternatural or perverted action of the uterus. I believe, however, that a careful consideration of the facts of various recorded cases will tend to shew that neither of these extreme views is correct; and that, whilst in a large number of cases it has been immediately occasioned by improper interference, in others it has occurred spontaneously, or at

least in the absence of any such cause. Smellie, for instance, relates a case in which it was occasioned "by the midwife's pulling at the placenta with too great force." (*Cases in Midwifery*, vol. iii, p. 494.) Mauriceau gives a case which was occasioned by "violent extraction of the placenta," and was followed by hæmorrhage during a period of eight months. (Tom. ii, obs. 355, p. 294.) Gifford reports a case, in which "the midwife, in attempting to bring away the placenta, inverted the uterus." (*Cases in Midwifery*, p. 421.) Chapman relates a case, of which the midwife told him "that the afterbirth stuck so fast in one part that she was not able, with all her strength, to take it from her, though she had gained the most of it." Upon this, the patient having died, he desired to see the corpse, and found, to his great surprise, "that the uterus was inverted, and entirely out of the body, with the placenta adhering to its fundus. The patient," he adds, "had a very good and easy delivery of the child; but that born, the midwife pulled hard at the string and so brought down the uterus."

as soon as she could take hold of she did, and then pulling with fresh violence, and not being deterred by the loud cries of the poor miserable woman, who, in a few minutes, fell into strong convulsions and deliquia, and so expired." Perfect relates two cases of inversion, which were caused by improper mechanical interference. In the first, the midwife, "after waiting some time in expectation of the secundines, was at length induced to pull with very great force at the funis, by which the accident was occasioned." In the second, "the patient had a severe labour of three days and nights, and lost her life by the hasty and violent manner in which the midwife pulled at the funis, and by which means an entire inversion of the womb was brought on." (*Cases in Midwifery*, vol. ii, pp. 6-9.) Mr. Barker reports a case which was occasioned from the interference on the part of a midwife. "At the end of half an hour after the birth of the child the placenta had not separated, and she accordingly proceeded to remove it, in doing which she employed so much force that she dragged out the after birth and uterus together." (*Med. Phys. Journ.*, vol. xxv, p. 210.) Other cases might be quoted to show that this accident has evidently arisen solely and entirely from undue traction upon the cord or some improper interference in the management of the placenta.

On the other hand, well authenticated cases may be adduced to show that inversion of the uterus has occurred spontaneously, or at least in the absence of any mechanical interference. Dr. Humphreys Storrer relates the following. "He was called to a woman in labour. In ten or fifteen minutes there came two smart pains, and the child was born. In five minutes the placenta was thrown off. The cord was not touched, except to divide it and remove the child. On putting his hand under the clothes, to take away, as he supposed, the placenta, he found that he had hold of the placenta with the uterus attached." (*Medical Gazette*, December 1842, p. 428.)

Two cases of spontaneous inversion of the uterus are referred to by Dr. Mitchell, in the *Dublin Medical Press* for September 23rd, 1846. The first occurred in the practice of Dr. Ashwell, who states, "that it was entirely spontaneous; for a friend, who was present during the labour, assured him that the midwife did not touch the cord. The child was expelled very quickly, and the patient felt a sudden pain, and said that something else was coming. On examination, Dr. A. found the uterus completely inverted, with the placenta adherent." In the second case, quoted from Dr. Lever, "the patient was delivered after a quick labour of a living child. In a few minutes, without any traction upon the cord, the patient complained of sudden pain, and said that something more had been expelled. The surgeon immediately passed his hand above the pubes, but could not detect the womb; and an attempt to make a vaginal examination satisfied him that the uterus was completely inverted." Mr. Clarkson reports the following. "He was called to a lady, aged 34, a short stout woman, then in labour of her eleventh child. He found her walking about the house apparently very comfortable, having had but few pains, and those at long intervals, during the day. Her former labours had been quick. On examination *per vaginam*, the head was found low down in the cavity of the pelvis, and the labia and perineum soft and dilatable. As yet, there had been no uterine contraction since he had entered the room; but just as she was getting off the bed, in order that it might be more comfortably prepared, a violent pain came on, and almost before he could apply his hand to the perineum the child was expelled, and the placenta brought to the os externum by the continuance of the same pain. Having hastily tied and divided the funis, and removed the placenta, which was perfectly loose, he found, on examination, that the uterus was partially inverted." (*Lancet*, vol. ii, p. 406.)

In the case I have related, I am informed by the gentleman who attended, that no undue traction was made upon the cord, that the placenta came away with ease, and that until he made a vaginal examination he had no reason to suspect that the uterus had become inverted. I think it

impossible to conclude from these facts otherwise than that inversion of the uterus may be both spontaneous and the result of improper mechanical interference; and from a knowledge of this circumstance, we may learn, not only the necessity of extreme caution in the management of the placenta, but also the possibility of inversion occurring even where no violence has been used.*

SYMPTOMS AND DIAGNOSIS. The symptoms of inversion vary very considerably in different cases, and in all are materially modified by the extent or degree of the displacement. When complete, the symptoms are for the most part of a marked and severe character. The constitution is profoundly impressed, and the immediate consequences are, in the words of Mr. Newnham, "hæmorrhage more or less considerable, accompanied with pain and expulsive efforts, and rapidly followed by syncope, convulsions, nausea, vomiting, hiccup, and sometimes death". When, on the other hand, the inversion is partial or incomplete, the character of the symptoms will mainly depend upon the extent of the displacement. In simple *depression* there may be little more than hæmorrhage, and an unusual prostration of the constitutional powers. In *introversion*, in addition to increased constitutional disturbance, as indicated by pallor, clammy skin, feeble pulse, and other symptoms of nervous depression, there is usually inordinate hæmorrhage accompanied by fulness, weight, uneasiness in the vagina, and constant expulsive efforts. In *perversion* the local and constitutional symptoms are of a still more aggravated character. There is great distress, alarming restlessness, clammy perspirations, cold extremities, a rapid feeble pulse, vomiting, with, in some cases, convulsions, delirium, and syncope. In the case I have reported, there was profuse hæmorrhage and uterine pain of such an agonising character as to render the patient delirious. I do not, however, feel it necessary to dwell at greater length upon this part of the subject, but will content myself with observing that, when in connexion with a rapid labour or any difficulty in the extraction of the placenta, a patient is attacked with either syncope, restlessness, hæmorrhage, inordinate uterine pain, or expulsive efforts, the possibility of the existence of inversion should be suspected, and a careful examination made of the hypogastrium, and of the uterus *per vaginam* and *per rectum*, which will inevitably lead to its discovery, if present.

In the chronic stage, inversion of the uterus may be confounded with either prolapsus or polypus. From the former, its diagnosis is comparatively easy; from the latter, more difficult. Much stress has been laid upon the sensibility of an inverted uterus on the one hand, and the insensibility of a polypus on the other; but this ground of diagnosis, so far as it rests upon mere tactile examination, appears to me to be of a very doubtful character. In the case which I have recorded, the sensibility of the uterus to the pressure of the finger was extremely questionable, and repeated trials left me uncertain as to whether any distinct pain was occasioned by pressure or not. I would suggest that the fact of the inverted portion of the uterus being in a state of strangulation, from the constriction of the surrounding cervix, must very materially modify, if not in many cases completely annihilate, its sensibility; and that a better test of the character of the tumour would be the cautious introduction of the speculum. This, at least, was attended with considerable advantage in the case I have recorded. As distinguished from a polypus, which was ob-

* It forms no part of the object of this paper to inquire into the mechanism of inversion; but in using the term spontaneous, I may be permitted to observe that it is intended to apply to cases which have occurred in the progress of labour, independently of any artificial assistance. In such, doubtless, the causes which tend to the displacement are of a complex character, and require not only that the placenta should be attached to the fundus uteri, but also that some undue pressure should be made externally upon this part of the organ, or some traction upon the funis below. This latter may occur, in the unassisted birth of the child, either from the funis being preternaturally short, or shortened by being coiled round some part of the child, or by the child being expelled with great force or otherwise, so as to produce a strain upon the cord. Inversion, thus commenced, will doubtless be increased and completed by the action of the uterus; but, being throughout independent of any extraneous force or assistance, may fairly be regarded as spontaneous, although both physical and vital causes co-operate and are necessary for its production.

served by Dr. Gooch to be of a pale flesh colour, mottled, or rather streaked with large blue veins, the inverted uterus was found to present an uniform pale red or salmon colour; and on touching it with the blunt end of a probe, not only was pain distinctly felt, but fine capillary streams of blood were seen to issue from the several points of the tumour touched by the instrument.

PROGRESS AND TERMINATIONS. The progress and termination of inversion of the uterus, when uninterfered with by art, is well illustrated in the case I have related; and it is more especially instructive, as showing not only how sudden and profuse are the hæmorrhages to which it may give rise, but also how little amenable they are to remedial measures, and consequently how uncertain is the tenure of life under such circumstances. Reverting to the occurrence of hæmorrhage in this case, it would appear that, for some weeks after labour, it had been more or less persistent and profuse. At the end of two months it had entirely ceased, and under the treatment adopted in the infirmary did not recur for three weeks. Then came a menstrual period, which for four days appeared to be normal; then followed a sudden and profuse loss of blood, so considerable as to endanger her life. Then came a cessation, followed again by hæmorrhage, equally profuse; and when red blood had ceased to flow, a drain of colourless fluid continued to escape from the inverted uterine surface, until the constitution of the patient was undermined and her vitality exhausted. With regard to the danger and fatality of inversion of the uterus, Mr. Crosse, in his memoir on the subject, states that, upon by far the most extensive data that have yet been furnished, he is prepared to affirm that above one-third, under whatever circumstances, or in whatever degree it may occur, prove fatal either very soon or within one month after its occurrence. Of one hundred and nine fatal *post partum* cases, collected from various authenticated sources, he found that seventy two, or two-thirds, proved fatal within a few hours after delivery, and most of them within half an hour or an hour. Eight proved fatal in from one to seven days; six in from one to four weeks; one in from four to five months. Of the remaining twenty-two, twelve proved fatal at the following periods; one at eight months, three at nine, one at twelve, two at twenty-two, one at two years, one at three, two at four, and one at five.

TREATMENT. Such being the natural course and tendency of inversion of the uterus, we have in the last place to consider what means can be adopted for its cure or mitigation. And first, it may be observed that all writers are agreed as to the extreme importance of promptly recognising it when present and immediately attempting its reduction; for the delay of even a few hours has sometimes rendered this impossible. Dr. Denman found it impossible to replace the organ after a lapse of four hours. Dr. Merriman was called to a case but a few hours after the accident had happened, and was unable to reduce it. Mr. Nelson relates a case, where reduction was impossible half an hour only after the inversion had taken place; and in the case I have reported, attempts were made to replace the uterus on the first and sixth days after delivery without the least success. The general experience, moreover, of the most eminent obstetricians, supports the observation that the most favourable period for effecting a reduction is that which immediately succeeds its occurrence.

But, at the same time, it may be observed, that cases are recorded in which the attempt was successfully made many days and weeks after the accident had occurred; and I am more particularly anxious to direct attention to the advantages likely to be derived from the induction of anæsthesia, when any difficulty arises in the reduction of the organ. I am the more led to do so, because I was not myself aware that this practice had been successfully adopted when the case I have reported was under treatment; and because, on suggesting it to various professional friends who visited the patient with me, I found that they were decidedly opposed to it, as being altogether futile. The following reference to cases where reduction was effected

under anæsthesia, at lengthened periods after the accident had happened, may therefore prove useful, and serve to induce a trial of it in others.

M. Valentin reports the following:—On the 8th of April, 1846, a female, aged 20, of good constitution, was delivered of her first child. Inversion followed, and was attended by leucorrhœa and syncope. The former continued during an entire month, and was then replaced by a persistent hæmorrhage. On the 15th of August, 1847, the reduction was attempted; but the screams of the patient caused the operation to be abandoned. On the 26th, another attempt was made with the aid of ether inhalation. The patient being rendered insensible, the same manipulations were gone through; but, as before, the uterus was altered in form, without the fundus yielding as was wished. The attempt was persisted in for ten minutes without progress, when etherisation was carried to the extent of relaxation of the sphincters. At this moment, the collapse of the system was complete; and the uterus partaking of the relaxation, the fundus allowed itself to be depressed under the finger, until it at length became suddenly restored to its normal state. In order to assure himself that the reduction was complete, the operator introduced his finger into the uterine cavity. (*Revue Médico-Chirurg.*, Nov. 1847.)

Dr. Merriman quotes a case in which reduction was successfully performed, long after its occurrence, by M. Barrier, at Lyons. The operation is thus described. The patient being placed on her back, the hips brought to the edge of the bed, the thighs separated, and etherisation effected, M. Barrier introduced his hand into the vagina. To give the uterus as much fixedness as possible, he placed it in the hollow of his four fingers; then, by pressing with the ball of the thumb applied directly to the fundus uteri—the most dependent part—he pushed it back in the direction of the axis of the outlet, with the intention of placing the neck of the uterus against the sacrum, and of supporting the extremity of the vagina by a resisting medium, in order to guard against its rupture. After a few minutes of gentle but sustained pressure, the fundus uteri had entered into itself from two to three centimètres. The same pressure was still kept up for an instant, when, feeling the organ gradually give way, the operator passed his index and ring fingers into the depression, where his thumb had begun to lodge itself, as he pressed back the fundus uteri. With these two fingers, he changed the direction of the force, without increasing its amount; he then pushed back the fundus uteri from below upwards, and from before backwards. Immediately the uterus yielded completely, and took again its natural position. (*Med. Times and Gazette*, Sept. 4th, 1852.)

Mr. Canney publishes a case of chronic inversion, in which reduction was successfully performed some months after the occurrence of the accident, under the following circumstances. The patient was laid on her right side diagonally across the bed, the nates projecting over the edge of the bed, and the knees being well drawn up, chloroform was administered to the extent of producing complete relaxation of the sphincters. The fingers of the right hand, formed into a cone, were now applied to the os externum; and, as soon as the chloroform had been inhaled for a short time, the entire hand passed almost without resistance into the vagina. The tumour was now grasped between the fore and ring fingers; it was supported in front by the thumb, and the point of the middle finger was applied to the apex of the tumour: the hand, with the wrist extended, was carried up, until the vagina was put fully on the stretch; and then, by slightly flexing the wrist, the tumour was gently pushed forwards and upwards, in the direction of the axis of the brim of the pelvis. As soon as the patient came under the full anæsthetic influence of chloroform, the tumour gradually receded, and the inversion was successfully reduced; the whole operation, from the first inhalation of chloroform, not occupying more than five or six minutes, and the force used being almost trifling. (*Med. Times and Gazette*, Sept. 18th, 1852.)

In a fourth case, Dr. Ayer succeeded in reducing an

version, thirty hours after it had taken place. He observes, "Having reflected on the relaxing effects of ether on the tissues, I determined to give it a trial, and, accordingly, while the inhalation was gradually conducted by an assistant, I grasped the fundus uteri, and made gentle pressure. As the system became relaxed, the tumour gradually diminished. In thirty minutes, the vulva became perfectly flabby, and the tumour soft and compressible. I made firmer pressure, and it was reduced to the size of a hen's egg; the finger could circumscribe it. It remained from twenty to thirty minutes of this size, uncertain whether further ground could be gained, and then disappeared *per saltum*, with the peculiar feel of a receding hernial tumour." (*Canada Med. Jour.*, July 1852.)

The success attending the reduction of the uterus in these cases, in a state of anæsthesia, appears to have been of an unequivocal character, and such as to justify our having recourse to it in others, before deciding upon the impracticability of reducing the organ.

But, should such attempts fail, and the patient's life be endangered by hæmorrhages or other exhausting discharges, we have then to consider the propriety of removing the inverted portion of the uterus. For this purpose, two methods have been employed, viz., excision and ligature; but the results of neither, it must be added, have been of a very encouraging character. The dangers attending excision are so great, that we are told, with reference to a case in which it was successfully performed by Velpeau, that the jeopardy of the patient was such, that it will doubtless not be often repeated; and, with regard to ligature, although many successful cases are reported, there is yet a formidable array of others in which it has proved fatal. Under these circumstances, I was led to believe that the electric cautery might be more successfully employed for the extirpation of the organ; and in this opinion I was supported by Mr. Marshall, who, after visiting and examining the case, expressed himself favourably of the operation. Unfortunately, unforeseen difficulties arose in the preparation of the necessary instruments; and, before their completion, the patient had sunk under the influence of sudden and profuse losses of blood. As, however, these difficulties have now been overcome, I will, before concluding, describe the nature of the apparatus by which the operation was proposed to be performed.

The battery intended to be used was necessarily one of considerable power; and to its terminal poles a modification of Gooch's canula instrument for the removal of uterine polypi was to be affixed. As now completed, this consists of two rods, one of which is solid, the other hollow, and covered with a wave flax surface, coated with solution, to insulate the platinum wire or chain which passes through it. One end of this wire or chain, of proper thickness, is soldered to the extremity of the solid rod; the other, having passed through the interior of the tubular one, is attached to a rack and windlass, affixed to the lower part of it. In using the instrument, the two rods are introduced together parallel to each other, and, having reached the neck of the inverted portion of the uterus, are then separated, and passed round it, as in the ordinary operation for removing a polypus: their upper extremities are fixed together by means of a silver sliding rod, having rings at its superior extremity. The platinum wire having been now tightened by means of the rack and windlass, the two rods are respectively affixed to the poles of the battery; and the platinum wire being heated by closing the circuit of electricity, it is gradually tightened by turning the windlass until the division of the organ is accomplished.* I am unable to speak from experience of the practical working of this contrivance; but I am disposed to think that it, or some modification of it, may be usefully employed for the operation in question.

Reviewing, then, the chief circumstances of the case I have reported, I would more particularly wish to direct

attention to the importance of the following considerations:—

1st. A due appreciation of the circumstances under which inversion of the uterus is most liable to occur in connexion with parturition, viz., rapid labours on the one hand, and those attended with any difficulty in the extraction of the placenta on the other.

2nd. The necessity of immediately effecting the reposition of the organ. Should any difficulty arise, we may either have recourse to anæsthesia, or adopt the suggestion of Millot, of incising or dividing the cervix, so as to take off the constriction thereby exercised upon the fundus uteri.

3rd. In cases of chronic inversion, where serious symptoms arise, the possibility of effecting the reduction of the organ whilst the patient is in a state of anæsthesia.

4th. The futility of any local or constitutional treatment in arresting the hæmorrhages which occur in these cases, and consequently the expediency of attempting the removal of the inverted portion of the uterus where reduction is impossible, and where these evince a tendency to recurrence.

5th. The dangers attending removal of the uterus both by ligature and excision being considerable, the propriety of attempting its extirpation by means of the electric cautery, aided by the apparatus I have proposed, or some modification of it.

Chester Place, Hyde Park Gardens, July 1853.

STATISTICAL ACCOUNT OF OBSTETRIC CASES, IN PRIVATE COUNTRY PRACTICE.

By R. U. WEST, Esq.

THE following statistics may perhaps interest some of the readers of this Journal. They give the history of about nineteen years of a private midwifery practice. In arranging my materials, I have found considerable pleasure in looking back upon a vast number of troubles, doubts, anxieties, and difficulties. I hope that they will not be looked upon as interesting to myself alone. Without further preface I subjoin my statement.

NUMBER OF CASES.

2,083 labour produced 2,106 children, viz.: 1,060 boys and 1,046 girls. 364 cases were primiparous, or 1 in 5½.

These 2,106 children were born with the following

PRESENTATIONS:

2,042 children presented some part of the head. Of these, 1,962 were expelled with the *occiput under the arch of the pubes*: In

3 cases where the head was so expelled, a *hand was down by the side of the head*.

3 were cases where the head was expelled with the *occiput turned to the left acetabulum*.

59 were cases where the *face or forehead came round to the symphysis pubis*, or 1 in about 35½: In

49 of these cases the head was so expelled: In 1 case where the head was so expelled, a *hand was down by the side of the head*. In

1 case where the face had come round to the pubes, the pains forced the chin under the arch, and the *face disengaged itself first*. In

1 other case, feeling the nose arrested at the symphysis, I pulled at the orbits till the chin came under the arch, and the child was born with the face first.* In

* In both these instances the labour was completed almost immediately after the alteration of position. They were both conversions of the worst form of cranial position into the easiest form of face-position. Madame Hoin says: "Nous avons vu un exemple de cette manière de dégager la tête. Feu Bédard, professeur à la Faculté de Médecine, nous en a cité un cas semblable."—*Mémoires de l'Art des Accouchemens*, tom. i, page 230.

* The apparatus in question has been constructed by Mr. Coxeter, who will give any further information that may be required respecting it.

- 8 other cases, after the face had come round to the pubes, I rectified the position of the head by pressing the temple, and bringing the occiput to the arch of the pubes.
- 3 were cases where the head was expelled with the face turned to the acetabulum. In
- 2 cases, the ear remaining at the symphysis, with the anterior fontanelle presenting, I turned the head round till the occiput came to the arch.
- 10 children presented the face, or 1 in 210, in addition to the two cases of secondary face-position mentioned above. In
- 6 of these cases the labour was marvellously quick and easy, although in four out of those six the chin was at first turned backwards towards the sacro-iliac synchondrosis. In
- 4 only did there appear to be any increase of difficulty in the progress of the labour. In one of these, a primiparous case, the face was forced through the pelvis, with the lower jaw pressed back on the neck or chest. And in one, a hand presented with the face.
- 1 child presented the occiput, shoulder, and one hand.
- 2 presented the ear. In
- 1 of these cases the shoulder presented with the ear.

2,042 Total presentations of some part of the head.

- 56 children presented either the breech or the inferior extremities. Of these,
- 27 presented the breech; and
- 29 presented one or both inferior extremities. In
- 3 instances a knee was first felt. In
- 8 instances the breech was down as low as the feet. And in
- 1 instance a hand was felt just above the feet.

56 Total presentations of breech or inferior extremities, or 1 in 37½.

- 8 children presented one or both hands, in addition to the six cases above mentioned, where a hand was down by the side of the head or face. In these eight cases turning was performed. In
- 2 of them, a foot being felt just above the hand, turning was very easy. Thus,
- 8 was the whole number of strictly transverse presentations, exclusive of the two cases mentioned, where the shoulder was down with the side or back of the head—1 in 266½.

COMPLICATIONS.

- 9 labours were complicated with prolapsed funis. In
- 2 of these cases the children were born alive, the delivery being hastened with the vectis in one instance. In
- 2 the children were putrid. In
- 2 the placenta was near the os uteri, and the labour was attended with hæmorrhage. In
- 6 there was malposition of the child, viz.:—feet presentation in three cases; arm down in one case; hand with head in one case; breech presentation in one case.
- 32 were cases in which instruments were used; viz.:
- 22 vectis.
- 2 long forceps.
- 2 blunt hook.
- 6 craniotomy.

The vectis was used, once on account of hydrocephalic head; twice in one patient on account of an exostosis projecting into the pelvis; once to hasten the birth in a case of prolapsed funis; twice where the face had come round to the pubes; and once in a case of face presentation. The rest were cases of impaction from various causes, such as

unusual size of the child's head, and presentations of the anterior fontanelle, all terminating with the occiput under the arch of the pubes.

In all the cases in which either the vectis or forceps was used, the children were born alive, and, with two exceptions, were quite uninjured. In those two instances (both of them vectis cases), one of the children died two days after (a face to pubes case); the other survived only five hours, being the one which had presented the face.

The blunt hook was used in two cases of impacted breech. In one of them the child weighed thirteen pounds and a half. Both children were born alive.

In two of the cases in which craniotomy was practised, I had the advice and assistance of other practitioners. In the other four cases I used my own judgment. In all of them the vectis and forceps were first tried in vain.

In all the cases in which instruments were used, the mothers recovered without the occurrence of a single unfavourable symptom.

48 labours were complicated with hæmorrhage.

21 of them were cases in which considerable hæmorrhage preceded and accompanied the labour. In

7 of these cases the placenta was felt over or near the os uteri.

In these 21 hæmorrhagic cases all the children survived, with the exception of three where the placenta had presented, one in the other cases, and three which were decomposed before birth.

9 were cases in which considerable hæmorrhage followed the birth of the child, in consequence of retained placenta.

3 labours were attended with hæmorrhage both before and after the delivery of the placenta. And

15 labours were complicated with hæmorrhage after the removal of the placenta.

2 cases occurred of secondary hæmorrhage, one at the end of a week, the other thirteen days after delivery.

In all the instances in which hæmorrhage occurred, the mothers recovered. The proportion of hæmorrhagic cases is 1 in about 43 cases.

34 cases occurred in which the placenta was retained or adherent, requiring the introduction of the hand,—1 in 61.

7 examples occurred of knots on the funis, two of them being very complicated.

4 cases were met with, in which the coccyx was projecting and ankylosed, three of them being in one patient. In all of them the bone gave way at last with an audible snap.

9 cases were noticed in which there was disease of the placenta. And in

1 case, the funis divided into its vessels before its insertion into the placenta.

23 labours, or 1 in 90, were cases of twins. One of them was a case in which the children were united at the sternum, constituting the form of monstrosity denominated by Geoffroy St. Hilaire, "Sternopage".*

Malpositions are much more frequently met with in twin cases than in single births: thus, my practice has furnished the following

PRESENTATIONS IN TWIN CASES.

- 9 cases—first child, vertex; second, breech or feet.
- 1 case—first child, vertex; second, face to pubes.
- 1 case—first child, vertex; second, face to pubes with a hand down.
- 3 cases—first child, vertex; second, hand presentation.
- 1 case—first child, feet; second, face to pubes.
- 1 case—first child, breech; second, feet.
- 1 case—both feet (in the monstrosity case.)
- 1 case—first child, face to pubes; second, vertex.
- 5 cases only in which both children presented naturally.

* *Anomalies de l'Organisation*, tom. III, page 98.

MATERNAL DISEASES.

13 mothers were suffering from different diseases at the time of labour, viz.:—

- 1 from scarlatina.
- 1 from fever.
- 1 from peritonitis.
- 1 from chronic bronchitis.
- 1 from pneumonia.
- 2 from chronic abscess under the fascia of the thigh. Both these cases occurred in the same patient in two consecutive confinements.
- 1 from cholera.
- 1 from excessive œdema.
- 2 from measles. In one case the child was born with the eruption.
- 1 from chronic gastritis.
- 1 from umbilical hernia.

13

88 cases of puerperal and other diseases arose within the month.

- 22 cases of peritonitis, puerperal fever, or hysteritis.
- 14 cases of intestinal fever or irritation.
- 6 cases of phlegmasia dolens.
- 6 cases of mania. Three times in one patient.
- 2 cases of intermittent fever.
- 1 case of intermittent pain with fever.
- 1 case of "hystericalgia" (Burns).
- 5 cases of ephemeral fever.
- 6 cases of diarrhoea with quick pulse.
- 1 case of pleurisy.
- 2 cases of rheumatic fever.
- 3 cases of convulsions.
- 5 cases of retention of urine without other disease. Three of these cases required the catheter.
- 1 case of pneumonia.
- 13 cases of inflammation and suppuration of mamma, with severe constitutional disturbance and fever.
- 2 cases of hysteria.

88

MATERNAL DEATHS.

16 mothers died either from puerperal diseases, or from other diseases arising during pregnancy. Of these—

- 10 died of diseases strictly puerperal; viz.:—
 - 2 of mania: 1 on the fourteenth day, primiparous: 1 on the eighteenth day; this was the third attack with the same patient.
 - 4 of peritonitis: 2 on the tenth day: 2 on the seventh day.*
 - 2 of intestinal fever: 1 on the thirteenth day: 1 on the thirtieth day.
 - 2 of phlegmasia dolens: 1 on the thirty-sixth day, from gangrene of both legs: and 1 on the tenth day from metastasis.
- 6 mothers died within the month from diseases arising during pregnancy, most of them inducing premature labour, viz.:—
 - 1 of scarlatina, commencing three days before the labour. Labour at full time. Death on eighth day of lying-in. Child living.
 - 1 of peritonitis, commencing eight days before delivery. Labour premature. Death on the sixth day of lying-in. Child living.
 - 1 of pneumonia, preceded by cynanche tonsillaris, inducing premature labour in seventh month. Death three hours after. Child still-born.
 - 1 of chronic bronchitis, existing long before delivery. Labour premature. Child living.
 - 1 of cholera, beginning two days before delivery. Labour premature. Death two hours after. Child still-born.

* One of these cases occurred with a woman who had been forty-eight hours under the care of a midwife with arm presentation, before I was sent for. The other was with a *primipara*, after a rather sharp labour. All the other deaths occurred with women who had had particularly easy labours.

1 of chronic gastritis, with vomitings and diarrhoea during latter months of pregnancy. Labour at full time. Death on the twenty-seventh day of lying-in. Child living.*

Therefore, the proportion of deaths from all causes would be one in 130 nearly; of deaths from diseases strictly *puerperal*, one in about 208 cases. But can we, from such data as I have here given, arrive at any knowledge of the average danger of death to lying-in women? If a correct average of the number of times each woman is confined can be made out, by comparing the number of cases in one's practice with the number of *primiparæ*, we have only to take the number of deaths and the number of *primiparæ*, and we shall arrive at a result. There were 364 *primiparæ* among my 2083 cases, and 10 puerperal deaths. I would conclude, therefore, that one lying-in woman in about 36 may probably die of some puerperal malady; that is, always supposing that my statistics give anything like an average.

DISEASES, MALFORMATIONS, MONSTROSITIES, OR OTHER CONGENITAL PECULIARITIES IN THE FETUS.

- 1 hydrocephalus, uncomplicated; lived two or three years.
- 1 hydrocephalus, with spina bifida; lived three days.
- 1 lobes of ears wanting.
- 1 eyes diseased through apparent want of power to close the lids. Eyes burst, and child died at the end of about six weeks.
- 4 well marked cases of the peculiar swelling of the scalp, in some respects analogous to spina bifida, and called by German writers, *kopfblutgeschwulst*.
- 1 palate wanting.
- 2 double harelip.
- 1 ascites; lived a few days. There was redundancy of liquor amnii in the case.
- 1 united, or "Siamese twins"; the sternopage of Geoffroy St. Hilaire. Still-born.†
- 1 spina bifida, uncomplicated at birth, but followed by hydrocephalus and club feet. Child lived six months.
- 1 a swelling of the nature of spina bifida on the sacrum. Child died of hydrocephalus when about a year old.
- 1 large hernia into sheath of funis; the opening through the abdominal parietes being as large as a crown-piece. I returned the intestines into the abdomen, and put on a bandage. The child survived, and is now living (aged five years), with a dense membrane filling up the original opening.‡ A little more, and the sheath of the funis would have burst, so that the case would have been one of eventration.
- 1 an exencephale,§ with eventration of all the abdominal viscera. The placenta was enormously hypertrophied. Still born.
- 1 inverted feet.
- 1 the cerebellum was contained in a bag of integuments hanging down the back. There was an opening through the centre of the occipital bone as large as a two shilling piece. The child lived five weeks. A case of partial nomenclature (St. Hilaire.)||
- 1 born covered with the eruption of measles, with which the mother was affected at the birth.
- 1 supplementary little finger.
- 1 born with a tooth.

STILL-BORN CHILDREN.

Of 2,106 children, 74, or 1 in 28½ nearly, were *still-born*, from various causes. Of these,

* When this patient died, she had been about three weeks under the care of another medical man.

† I published an account of this case in the *Edinburgh Med. and Surg. Journal* for October 1847.

‡ A remark made by an old nurse who was present at the birth of this child amused me excessively. She had been with me also at the birth of one of the spina bifida cases a short time before in the same village. She said: "Well! I don't know what's going to come to all the bairns. Not long ago, one was born without a back; and now here's one come without a belly!"

§ A monster with the brain uncovered by the skull, and with cleft spine; so named by St. Hilaire. *Anomalies de l'Organisation*, tom. ii, page 311.

|| *Anomalies de l'Organisation*, tom. ii, page 231

40 were decomposed at birth; 33 being premature, and 7 at the full time. I observed that, with one of the premature cases, there was *ramollissement* of the placenta; the heart was beating, though the cuticle was peeling off, as with putrid factuses. With one there was hypertrophy of the placenta; with one there was a kind of fatty degeneration of the funis, partially obliterating the vessels; and with one there was scirrhus of the placenta. With one of the decomposed children at the full period, I observed great redundancy of the liquor amnii; another was the first of twins. The proportion of decomposed children was 1 in 52 births.

6 craniotomy.

3 primiparous footling cases—delivery of head difficult.

5 from prolapsed funis. Of these, one was a case of arm presentation, in which the arm had been long down before turning was performed; one was a case of feet presentation, in which the edge of the placenta presented with great hæmorrhage; one was a case where the arm was down by the side of the head; one was a case of feet presentation, in which the pulsation had ceased in the funis when I first examined, the liquor amnii having been evacuated some hours with the funis down; and the fifth occurred in a case of vertex presentation, which, as it proceeded with great rapidity, I left to nature.

3 under placenta prævia (inclusive of one of the prolapsed funis cases mentioned above).

6 from the labour being unusually severe and protracted.

1 apparently caused by ergot, labour easy.

2 the monstrous twins.

2 ovum expelled entire in seventh month.

1 exencephale.

1 a midwife's case of arm presentation.

1 premature, placenta diseased.

1 premature, cause not manifest.

2 premature; mothers moribund, one from pneumonia, one from cholera.

1 premature, labour preceded by hæmorrhage.

The liability to recurrence in the same patient of any particular kind of obstetric disease or irregularity, is unquestionably of practical interest. A private country practice offers, I think, especial advantages to any one disposed to pay attention to such a subject; for, the number of practitioners being necessarily limited, and in some districts the practice being almost monopolised by a single individual, patients have scarcely the opportunity, even if they had the inclination, of changing their medical advisers. But, even with these advantages, it is, for obvious reasons, not possible to furnish from any practice a perfect list of such cases. The first set of patients have, for the most part, been attended in previous confinements by predecessors in the practice; and the obstetric history of a great many, in the latter years, can have only just commenced. In my own case, these causes have been doubly in operation; for having, after nearly sixteen years' practice in a village distant seven miles, removed to this place about three years and a half ago, I have, of course, added many altogether new patients to my list, while I do not retain more than half of my old practice. Nevertheless, I subjoin the following particulars, such as they are:—

Face to Pubes. Three times in succession with one woman out of ten labours; twice with one out of four labours; twice with one out of nine labours; twice with one out of five labours.

Presentation of Breech or Feet. Twice with one woman in four labours; twice with one in five labours; twice with one in five labours; three times with one in five labours; twice with one (the two last) in six labours.

Funis prolapsed. Twice with one woman in four labours; the first time with arm presentation, the second with vertex.

Peritonitis. Three times with one woman in five labours; twice with one woman in four labours.

Hæmorrhage post partum. Twice with one woman, in the last two of six labours.

Adherent Placenta. Six times with one woman in eight labours; three times with one in six labours; three times with one (the three last) in seven labours; twice with one in three labours; twice with one in six labours.

Still-born Putrid Children. Four times with one woman in five labours; three times with one in ten labours; twice with one in two labours; twice with one (the first and last) in six labours; twice with one in two labours; twice with one in three labours.

Mania. Three times with one woman in four labours, proving fatal on the last occasion.

Dysuria. Twice with one woman in three labours; twice with one woman in three labours.

Chronic Abscess under the Fascia of the Thigh. Twice in succession with one woman in four labours. This is rather a strange kind of case to be connected with pregnancy. The woman had recovered from the first abscess.

Anchylosed projecting Coccyx. Three times with one woman (the last three) of ten labours.

A particular kind of rigidity of the os uteri will occur repeatedly with some parturient women. I think I have observed two distinct kinds of rigidity. In one, the os is *thin*; it is met with most frequently in primiparous patients, and the head often presses the expanded cervix down into the pelvis so tightly, that it requires a practised hand to distinguish, at the first touch, the cervix from the head itself. I do not think this variety of rigidity is liable to recur with subsequent labours; in fact, it is seldom met with in any but primiparæ; at any rate, such has been my experience. In the other, the most troublesome and tiresome kind, the os uteri is *very thick*, and sometimes oval in form,—it is like an unexpanded or undeveloped cervix; the labour is excessively tedious and hard, and for many hours there will be unavailing suffering. This kind of rigidity seldom occurs with primiparæ, but will recur again and again with women who have borne one or more children; their previous labours, and now and then an intermediate one, being often remarkably quick and easy. Scarcely anything but patience will avail with such cases; but I fancy I have observed good effects from the application of belladonna ointment—the “pommade dilatatoire” of Professor Chaussier, from enemata, and from chloroform. I subjoin a few examples of recurring cases of this exceedingly unpleasant complication:—

Os uteri thick and rigid—labour very hard and tedious.

1. The second, fourth, sixth, and seventh of 7 labours.
2. The second and third of 4 labours.
3. The second, third, fourth, and fifth of 7 labours.
4. The second, third, fifth, sixth, seventh, and eighth of 8 labours.
5. The last four of 5 labours.

And there would seem to be great capriciousness in the recurrence of this affection, for the excepted labours were all particularly easy and quick; in one or two of them there having been literally “no time to fetch the doctor”. No. 5, in the above list, had peritonitis, requiring bleeding and much anxious attendance after the first and two last of her bad labours; and after the second of them, she had very severe afterpains, with deficient lochial discharge, but without abdominal tenderness or acceleration of pulse. No. 2 has had two very severe confinements since I left her neighbourhood, I suspect from the same cause; and yet her first (primiparous) confinement was very easy, and her fourth ridiculously so.

The list given above includes none but such cases as came under my own observation. I am enabled to add, from information derived from the patients themselves, and from other sources, the following facts.

The patient who had retained placenta on the second of the three last of seven labours attended by myself.

the same complication with her three first children under the care of my predecessor; thus suffering from the same cause six times in ten labours altogether.

One of the patients, who had *dysuria* twice under my care, has since suffered from the same malady under the care of another medical man.

A patient whom I attended a few years ago with *puerperal convulsions*, has since died of that disease under the care of another medical man; having had convulsions *twice* in four labours.

A woman, whom I delivered a few months since of a *still-born* decomposed child, which presented footling, had had four children previously; all still-born, all premature, all decomposed, and all footling.

One practical inference to be drawn from these facts must be, that when once a patient has had certain obstetric irregularities, she is liable to them again. And a second may be, that the proportion of individual women liable to certain obstetric irregularities is less than would appear from merely taking the proportion of such cases singly to the whole number of labours. Let us take, for example, the cases of adherent or retained placenta. I have registered thirty-four such cases. But it would be incorrect to assume from that fact that thirty-four women out of the whole number attended had suffered from that complication; for when we look at the table of cases just given, we find that sixteen of those cases were divided among only five patients, so that no more than twenty-three women were the subjects of adherent or retained placenta.

I have never attempted in my register to make any distinction between *quick* and *lingering*, or between *easy* and *hard* labours. In the first place, we are called in at all stages of labour; and it is impossible to arrive at any certain knowledge of the commencement of the process from the report of the patient herself, as women sometimes fancy themselves in labour many hours before there is any effect on the os uteri. And in the second place, no line can be drawn between *easy* and *hard* labours; because the two kinds run into one another by imperceptible gradations, and because some labours, which have commenced with rigid os uteri, will frequently, all at once, after hours of unavailing suffering, proceed with extraordinary rapidity; so that an accoucheur, arriving just at that moment, would certainly class as *easy* a labour which, if he had to his misfortune been sent for earlier, would as certainly have been classed as *hard*. Therefore, because we do not see all the labours in all their stages, I take it to be impossible to arrive at anything like a satisfactory division of labours into either quick and lingering, or easy and hard.

My statistics may to some persons seem incomplete in another respect. I have not given the different *cranial positions*. When I commenced my register, I did not consider myself competent to decide on points respecting which writers say there is so much difficulty;* and though, after some experience, I found little or no difficulty in distinguishing the fontanelles in the great majority of cases, I continued my register as I had begun it, marking no particulars but such as I have here given. I have, however, for the last three or four years been taking some pains with the *vexata questio* of cranial positions; and during the last year and a half I have registered the following particulars, adopting a classification of my own.

Of 235 children born in my practice since January 1, 1852, 222 presented the cranium. Of 57 of these, I was unable to ascertain the original position, either through putridity of the child, the too advanced stage of the labour, or because I was not present when child was born. Of the remaining 165 children,

106 presented the cranium in the first position, *i. e.*, with

the occiput coming round to the arch of the pubes from the left side;

49 presented the cranium in the second position, *i. e.*, with the occiput coming round to the arch of the pubes from the right side;

6 presented the cranium in the third position, *i. e.*, with the face or forehead coming to the symphysis pubis from the left side;

4 presented the cranium in the fourth position, *i. e.*, with the face or forehead coming round to the symphysis pubis from the right side.

In five of these ten face to pubes cases I rectified the position, after the face had come round.

The frequent occurrence of cases where the anterior fontanelle was felt, in an early stage, near the pubes, the occiput eventually coming quite round to the arch with the greatest facility, by degrees induced me first to search for an explanation in the works of obstetric authors, and secondly, when I could find nowhere any satisfactory explanation, but, on the contrary, the most discordant opinions among different writers, to study the subject for myself in my own practice. I have noted that among the 165 cases of cranial presentation above referred to:—

26 well-marked cases were observed where the anterior fontanelle was felt at first to the *left side* of the pubes. And

13 well-marked cases were observed where the anterior fontanelle was felt at first to the *right side* of the pubes.

All these cases terminated naturally and easily with the occiput under the arch. I have, therefore, classed them among the cases of the second and third positions respectively.

I consider that a classification of cranial positions, on any other principle than that of the four positions I have adopted for my own use, is fanciful and theoretical; because scarcely any two writers can be found to agree who make such an attempt. Between Ritgen, for example, who gives nine positions of the vertex,* and Nägele, who insists on forcing all cases into a sort of Procrustean arrangement of two positions only, I find a whole host of writers who give variously from eight to four positions, and who all differ from one another still further with respect to both the arrangement, and the relative frequency of those positions. And certainly of all subjects on which doctors differ, this would seem to be the most hopeless; for in the last published authority I have consulted, I find the writer dismissing the subject in a footnote, acknowledging himself staggered but not convinced by the arguments and assertions of Nägele.†

In making my observations on the progress of labour in cranial presentations, I have noticed one point which I have not found any writer refer to. Books tell us that when the head passes down the pelvis with the occiput to the left side, the right ear having been nearest the pubes, the right shoulder will come to the arch of the pubes when the trunk is expelled, and conversely. And that such is considered to be *invariably* the case, we have a proof towards the end of the footnote, in Dr. Ramsbotham's work already referred to; where he suggests that, when there remains any doubt as to the original position of the fetal head in the pelvis, we may decide on that position by observing how the trunk passes.‡ But, of course, if the trunk in coming to the outlet does not *invariably* follow the rule given, we cannot depend on the test proposed. Now, I noticed that in the 165 cases of cranial presentation, in which I distinctly made out to which side of the pelvis the occiput lay originally, having also in many of them verified my diagnosis by the presence of the

* Busch and Moser, after describing eight positions contended for by Ritgen, adds: "In einem Falle nimmt er sogar noch eine Lage zwischen der fünften und sechsten Stellung an."—*Handbuch der Geburtskunde*, b. iii, p. 327.

† *Principles and Practice of Obstetric Medicine*, etc., by F. H. Ramsbotham, M.D. Third edition. 1851. pp. 185-188.

‡ "By attending, therefore, to the mode in which the trunk passes, we may inform ourselves of the position which the child held in utero, and of the original direction of the fetal face."—*Vide note in Ramsbotham's Obstetric Medicine*, p. 188. Third edition.

* Nägele says, after making one of his dogmatic assertions in opposition to other writers: "Wer aber dieser Aeusserung wegen sich zu eutristen seyn möchte, der möge doch erwägen, für wie schwierig die Diagnose der Kopflagen von den grössten Meistern ausgegeben worden." And then he goes on to say that Roederer, speaking of face to pubes cases asserted, "nequit penitus cognosci, antequam caput est natum." And also that Smellie had freely acknowledged he had been mistaken.—Nägele, *Die Lehre vom Mechanismus der Geburt*, p. 40.

caput succedaneum, which is always found on the side which has been next the pubes, the shoulders were reversed no fewer than sixteen times; that is, where the right ear had been next the pubes, the left shoulder came to the arch, and conversely. Nägele, indeed, says that sometimes with roomy pelvis he has observed the shoulders entirely expelled with their greatest breadth in the transverse diameter,* that is, without either shoulder coming to the arch; but he alludes to no other deviation from the rule usually laid down. In my cases, the head twisted round soon after its expulsion, and the wrong shoulder came distinctly to the arch, not only in easy cases, but in some very hard ones. I need only mention one where I could not be deceived. In the early part of the labour I had felt the anterior fontanelle near the left acetabulum. The labour went on very slowly, though the pains were severe. The anterior fontanelle approached nearer the pubes. Thinking the labour was likely to be very protracted, I applied the long forceps, and with some trouble brought away the head. Just before expulsion, I felt the anterior fontanelle under the arch close to the left side of the symphysis. I found after birth the marks of the forceps, one on the right temple in front of the ear, the other on the side of the neck under and rather behind the left ear. My diagnosis was thus confirmed, by finding that the left side of the head had been the lowest, and consequently next the pubes in the first stage. But even in this case the right shoulder came to the pubes, and it required considerable traction to draw away the trunk, the child being a very large one. As I have been somewhat curious on this point, I have always been particularly careful after the birth of the head to allow the shoulders to take their own direction.

As I have given a hard case where the shoulders were reversed, I may as well add from my notes, written at the time, an example of an easy one, where the same phenomenon was observed. This case was one which occurred before January 1852, and is not included among the sixteen already referred to.

"No. 1846, December 13th, 1851. Anterior fontanelle felt near pubes, very close to it. Head quite disposed to descend, after rupture of the membranes with well dilated os uteri. Thinking this a case for spontaneous rectification, I contented myself with keeping a finger gently applied during the pains to the fontanelle, that I might accurately observe the changes. The sagittal suture was directed obliquely backwards, and the posterior fontanelle was felt distinctly near the sacrum, the anterior fontanelle being inclined slightly to the left side. Very rapidly, during one pain the head revolved, the anterior fontanelle passed upwards and to the left side of the pelvis, the posterior descended and passed round to the right side of the pelvis, and thence to the arch of the pubes with about two more pains, when it was expelled in the natural position. But the head continued to revolve, and the right shoulder passed under the pubic arch instead of the left, and thus the shoulders were expelled with the face turned to the right side of the mother, and the occiput to the left; although, as before said, in passing through the pelvis, the occiput was turned to the right side, and the face to the left". (Note in Register.)

In a future paper, I hope to be able to give the results of my observations on those interesting cases, in which, as in the one just quoted, the anterior fontanelle is felt in the first stage near the pubes. I think they can be satisfactorily explained.

Alford, Lincolnshire, July 25th, 1853.

CASE OF IMPERFORATE ANUS, WITH ABSENCE OF THE RECTUM.

By HENRY DAYMAN, Esq., Surgeon.

(Read before the Medical Society of Southampton.)

ON the 7th of March, 1853, I delivered Mrs. M., aged 36, of a fine healthy male child. On the 10th, I discovered that the infant was the subject of that peculiar arrest of development to which the term "imperforate anus" has been given. In the present instance, however, the anus was perfect; and within the apparently natural orifice there was a mucous surface, ending about three-fourths of an inch up, in a shut sac. Now, although the prognosis under this peculiar condition is confessedly unfavourable and the prospect from surgical interference most uninviting, yet, in this case it became at once evident that something must be done to relieve the pent up meconium. Accordingly I consulted with my friend Mr. Spear, of Eling, on the best plan of proceeding; and we arranged to meet the following day and perforate the sac, with the view of establishing a communication between the gut above and the imperfect rectum.

Mr. Spear and myself met on the next day, the 11th, having delayed our meeting several hours to allow the child to be baptized. Our services were not required for the living; the child had died a few hours before our arrival at the house.

A *post mortem* examination was at once obtained; and, with the assistance of Mr. Spear, I had the opportunity of making a thorough and elaborate investigation of the parts involved in this singular malformation.

The child was large and well formed, of natural colour everywhere, except over the abdomen, which was black, tense, and swollen, and its walls appeared so attenuated that one might almost imagine the convolutions of the intestines were visible through the parietes. On opening the abdomen, one immense object presented itself, which seemed to obscure every other. This was the descending colon, distended with meconium, and closed at its distal end, so that it rested on the bladder anteriorly, and on the iliac fossæ and lumbar vertebræ at the sides and behind. No portion of the colon was below the brim of the pelvis; but from it descended to the anal pouch a fibrous cord, which, on closer examination, appeared to be made up of condensed bands of pelvic fascia. I carefully removed the colon, together with the entire contents of the pelvis; and of these I subsequently made a minute dissection, with a view to discover whether any other, and what structures were implicated.

- | | |
|---|---|
| 1. The divided sacrum. | 6. The anal pouch. |
| 2. The divided os pubis. | 7. The levator ani, on the right side, which has been divided, and shown to show the connection of the pouch 4. |
| 3. The colon distended, and ending in a shut sac. | 8. The fibrous band between the colon and anal pouch. |
| 4. The bladder. | |
| 5. The fibrous band between the colon and anal pouch. | |

The only peculiarity which I observed was the absence of the rectum. The fibrous band mentioned was decidedly not a tube, but its entire length of being

and was continuous with the pelvic fascia before and behind. It possessed, so far as I could see, no vestige of proper muscular tissue; nor did the recto-vesical fold of the peritoneum appear. That membrane, on leaving the fundus of the bladder, was reflected over the enormous colon.

At the anal extremity, the appearances were natural. There was the retraction and puckering of the skin; and on dissecting deeper, the external sphincter was found perfect; but I cannot say that I discovered any circular band of muscle surrounding the pouch, which could be called the internal sphincter. The levatores ani were present and well developed, and together encircled the pouch just within the sphincter.

Milbrook, Southampton, June 27th, 1858.

HINTS ON THE CLIMATE OF AUSTRALIA.

By W. J. STERLAND, Esq.

[This paper has been communicated to us by Dr. COWAN, of Reading, who states that the author, though not a member of the medical profession, is entitled to speak with authority on the climate of Australia. EDITOR.]

THE salubrity of the Australian climate has been so much vaunted by almost every writer on the colonies of that vast continent, that it may appear an act of temerity in me to lift up my voice in opposition to the many who have lauded it as the healthiest climate in the world. Yet it is doubtful if these pages would have been written, had not an eminent physician suggested to me, that, having left England for Australia solely on the score of health, my experience of the climate might perhaps be useful to others; and it is on that account alone that I have ventured to pen the following remarks.

Before I set out for Australia, I had been suffering from ill health for some time; and, ere taking the important step of leaving my home for the antipodes, I very naturally consulted all the writers on the climate on whose works I could lay my hands. All (with only one exception) agreed in their accounts of its advantages. The exception was a little work by Dr. Clutterbuck,* a nine years resident in the colony; his statement alone varied from the rest, and he alone painted the climate in the colours which my subsequent experience has found to be correct. I believe his little book met with a good deal of opposition from the advocates of the colony, the writer being described as a disappointed man, who was endeavouring to revenge himself by depreciating the colony on a point which had always been strenuously insisted on as one of its chief advantages. However that might be, I know not; but, so unfavourable was his statement as to the healthiness of the climate, that I studiously kept back this book from some of my friends on this account.

The principal part of Australia that is colonised lies between the 28th and 40th degrees of south latitude, the mean annual heat being about 65° Fahr. In general, the atmosphere is a brilliant one; the extreme rarity and dryness of the air enabling one to see a far greater distance than is possible in England; indeed, the latter named quality, dryness, I believe to be its great characteristic. During the summer season, when there is a cool air stirring, there is a buoyancy in the atmosphere which I never felt elsewhere. Even during the rainy winter season, the air possesses the same quality; it may rain with almost tropical violence, but the air is free from dampness and clamminess; there are no walls streaming with condensed moisture, nor do the clothes steam on approaching the fire, as is so common in this country.

The season of spring commences in September, and is the most delightful part of the year; the ground is covered with an emerald verdure; and, though there are occasional showers, yet the sun shines brightly and cheerily, drying the ground which the heavy winter rains have deeply softened; too

much so, indeed, for the poor pedestrian, but not too much to fertilise the soil. In November, the summer heat commences, and then begins also that bane of the climate, the hot wind.

The interior of the vast continent of Australia, as far as it has been explored by Mitchell, Leichhardt, Sturt, and others, appears to be an interminable waste of sandy and rocky desert. Captain Sturt, who penetrated further to the northward than any other traveller, found himself in a desert of sandy hummocks alternating with bare rocks, and without a trace of vegetation or water. The heat was terrific; stones, that had lain on the ground in the sun, could with difficulty be held in the hand; the stirrups of the saddles became so hot, that the men could not always keep their feet in them; their nails became as brittle as glass; and all the horn handles of their combs and instruments split to pieces with the intense heat. A thermometer, hung in the shade at the back of a tree, rose to 132° Fahr., and in the sun to 157°! Only one living creature was observed: the wonder is, that any should be found in such a glowing region; but, perched on the highest and most exposed points of the rocks, where it was too hot to bear the hand for long, sat a beautiful little pigeon, with a long crest, the *geophaps plumifera* of Gould, seeming to find enjoyment in the heat which had driven all else living away.

The general opinion as to the cause of the hot wind is, that it becomes greatly heated in passing over the burning deserts just described; and I think the theory is so rational and sufficient to account for the effects, that no other need be sought for. The great proof of its correctness is, that the hot winds invariably blow from the interior to the colonies affected by them. In Port Phillip (now Victoria) they always blow from the north, and indeed I do not remember a north wind that was not a hot one.

We could always tell on rising in a morning, and sometimes before we left our beds, if the wind was in the north, even if we could not feel the heat. The sky, though generally free from clouds, wears a hard leaden aspect; and though at first there may be only a gentle breeze, yet it soon increases in intensity until it blows a perfect gale, driving the dust in clouds, while the sky has deepened into a lurid tint, and the sun has a coppery appearance. Every effort of course is made by those who have experienced the effects of these winds, to close all doors and windows, and every crevice that would admit a breath, in order to husband as long as possible the cool air which the house contains. In small houses the temperature within and without doors soon assimilates, while in larger ones the air can be maintained cool the whole day.

As the day advances, the heat of course increases, and the thermometer soon reaches 80°, but it still keeps rising until 82°, 84°, 86°, and sometimes 88° and 90° is attained; and this is within the house, and free from every breath of hot air. Out of doors in the shade the thermometer ranges from 90° to 105°, and sometimes higher; and I have known one instance in which it rose on a south wall (the cool quarter) in the shade, and within three miles of the sea, to 110°!!

During the summer season, rarely a week passes without one or two days of hot wind. Sometimes it blows for two days together; and on one occasion I experienced it without the slightest intermission for five consecutive days. I was told by a medical man in Melbourne, that one day more would have "laid half the people in Melbourne on their backs". The effects upon the human frame are, as may be imagined, extremely depressing; all energy is gone, one feels utterly exhausted, and gasps for breath like a fish out of water; but it is in vain that one opens a window to admit a little air to keep off the feeling of suffocation; a blast rushes in as hot as if it had just traversed a furnace, and one is quickly glad to close the window. Night draws nigh, and the wind generally changes at night; yet still it rushes on in the same violent monotonous manner. Suddenly there is a lull: one hastens to open the door. The hot wind has ceased; and in two minutes, sometimes less,

* Port Phillip in 1849. By J. B. Clutterbuck, M.D. London: J. W. Parker.

sometimes, though rarely, more, roaring over the tree-tops comes a south breeze, charged with cold from the Arctic ocean, and for a few minutes driving back the dust which all day long had been blowing in the opposite direction. When this has subsided, doors and windows are thrown open with a glad welcome, and thicker clothing is put on.

But if the wind should not change in the evening, matters are still worse. In the daytime there is something to attract attention, if one is almost melted; but at night there is no such resource, and one feels totally exhausted. Yet sleep is impossible; for the thermometer in the bedroom is never less than 84° or 85°, and the heavy monotonous groaning of the wind, as it rushes past, sings anything but a lullaby. There is nothing left but to lie on the bed, waiting and hoping for a change with as much patience as can be mustered. Often have I risen in the night and opened the window, in the vain hope that perhaps the wind might have changed without our hearing it.

It is, I believe, the extreme vicissitudes of the Australian climate, the great and sudden changes of temperature, that are so injurious to the constitution and so productive of disease. In the summer of 1851-2, on one occasion the thermometer at the back of my house, in the shade and facing the cool quarter, stood at noon during the prevalence of a hot wind at 107°; the next day at the same time and place it stood at 52°! This, I grant, was an extreme case; but I have frequently known a difference of from 10° to 30° in from two to five minutes, and indeed I never recollect an instance of a hot wind occurring, when the change to a south wind did not take place in the sudden manner I have described.

It must strike the most careless observer that such vicissitudes cannot be beneficial to health, when one hour you are perspiring copiously under the thinnest possible clothing, and the next glad to get to the fire-side, or put on winter clothes.

Fever and dysentery (as might be expected) are very frequent; and rheumatism, notwithstanding the dryness of the air, is far more prevalent than in England, a fact clearly to be attributed to the sudden changes of temperature. Consumption, too, is frequent, and fearfully rapid in its course; but I believe that, in its incipient stages, before any ulceration of the lungs has commenced, the Australian climate would prove remedial in its effects, if the extreme changes mentioned above were guarded against. Ophthalmia is very common, arising from the intense heat and glare of the sun, and the dust with which the air in summer is constantly loaded. During the summer of 1851-2, influenza made its appearance in the colony, and was very general in its ravages, few persons escaping a more or less severe attack.

I have found disease of every kind far more rapid in its course than in England; and generally speaking, it may be stated that the climate is fatal to the extremes of life, particularly to childhood, great numbers of children being annually carried off by dysentery and inflammatory diseases.

I have stated, at the commencement, that I visited Australia for the benefit of the climate, and the reader will be glad to learn with what success. The chief disorders from which I suffered, were a delicacy of chest without the presence of actual disease, and an extreme susceptibility to take cold. On these two points I found the climate highly beneficial; I have never felt the least symptom of weakness of chest since I landed in Australia nor since my return, nor have I ever had but one cold or cough during the same period. But, on the other hand, I suffered much from the depressing influence of the hot winds, and twice I was laid up with low typhoid fever, and fully expecting that the last attack would prove fatal.

I do not pretend to account for the manner in which the diseases I have mentioned are produced; this I leave to the physician. I have merely chronicled the result of my own experience during a few years residence in the colony; and the reader will be at no loss to gather that, on the whole, my opinion of the climate is unfavourable.

Great stress has been laid by writers on the Australian colonies on the fact, that persons, they say, may sleep out of

doors without any danger. During the summer season, when little or scarcely any dew or rain falls, a man may easily do this without risk, wrapped in his blanket or opossum rug; but at other times of the year it is almost as impossible as in England, and it argues great ignorance, or perversion of the truth, to take a few isolated months and hold them forth as a specimen of the whole year.

I may, perhaps, usefully conclude these notes by a brief description of the seasons as they occur. Spring, as I have elsewhere said, commences in September; and during this and the following month the weather is particularly fine and exhilarating, with frequent genial showers.

Summer sets in with November, and continues until the end of February, the latter being the hottest month of the year; the hot winds prevail during the whole of this season, and the dust during the same period is a constant plague. Within fifteen or twenty miles of the sea coast, the summer heat is tempered by the sea breeze; but beyond that distance it is much more intense. In general, little rain falls during the summer; but destructive floods occasionally occur in December, from heavy rains on the distant mountain ranges. March, April, and May, are the autumnal months, the last being frequently showery.

Winter begins in June and continues through July and August. The rains during these months are heavy and frequent, approaching the tropical in character. In the lower-lying country, the cold rarely produces more than occasional slight frosts, which are dissipated in an hour; on the high grounds and mountain ranges snow frequently falls to the depth of several inches, and ice is formed, of the thickness of a shilling, but neither last many days.

The mean annual depth of rain in Victoria is about forty-eight inches, the mean of London being only about twenty-two inches; a proof of the tropical nature of the winter rains, and of the rapid evaporation going on during the remainder of the year.

Reading, July 1853.

MASTURBATION IN A FEMALE APPARENTLY WITHOUT AN UTERUS; WITH REMARKS.

By EDWARD WADDINGTON, Esq.

THE following case came under my notice in the year 1848, while in practice in the country. By a reference to my case book, I find ample details of the case; but, as it would take up too much space to publish the whole, and as the case will lose nothing by being abridged, I shall adopt the latter plan.

Catherine Stevens, a finely formed, but sickly looking servant girl, aged 22, applied to me on account of frequent pains in the back, passing round to the loins. Upon inquiry, I found that these pains were first noticed about the age of sixteen, but were of so slight a nature, and so short in duration, as to attract but little notice. For the last few years, however, she had suffered more and more; the pains in her back appearing gradually to increase in strength and duration, recurring as nearly as possible every two or three weeks, seldom leaving so long an interval as a month, and lasting about three days. When first noticed, some years since, they did not continue more than half a day, or a night. She had never menstruated. From the peculiar pearly yellow appearance of the features, the tumid, discoloured skin, circle beneath the eyes, the pearly conjunctivae, the gummy white tongue, and feeble pulse, I came to the conclusion that this was simply a case of anasarca. For months I continued to treat this person for anasarca. She took at various times, one after almost all the emmenagogues in repute; but all avail. She was cupped on the loins; had leeches the vulva, and insides of the thighs; used hip-baths with no apparent benefit. I therefore insisted upon examination, to satisfy myself that no unnatural in- existed to render the

ment unavailing. I first directed my attention to the chest, and found the breasts well and fully developed, though rather more pendent and flaccid than usual in an unmarried woman at her age. The body was rather thin, but not emaciated; the muscles were relaxed and flabby. I found the organs of generation fully developed; the labia majora were large, and peculiarly flaccid; while the clitoris was prominent, appearing tumid, and very vascular. There was no appearance of the hymen. It was quite clear that this young woman had long been addicted to illicit connexion, although this was strictly denied. On introducing my finger into the vagina, I could find no os uteri. As the os externum was by no means small, I had no difficulty in making an extensive and careful examination. I found the vagina a perfect *cul de sac*; there was no trace at all of uterus. I was equally unsuccessful in finding the slightest indication by the rectum, or through the abdominal parietes. A medical friend (Mr. Ed. Gibson, of Huxey, Lincolnshire) by my request, made a long and careful examination, but came to the same conclusion, that no uterus could be found, and that this organ did not exist. A peculiar feature, remarked by this gentleman, as well as myself, was the large size of the vagina.

By strictly watching this young woman, and by frequent close questioning of her, the case was soon cleared up, or at all events, rendered more intelligible. Not only did she confess that she was in the constant habit of indulging in sexual intercourse upon every opportunity, but that she was addicted to the crime of masturbation to an extent scarcely credible. The failure of the constitutional effort at the establishment of the menstrual function, would partly account for her chlorotic appearance, and the pain in the lumbar region; but the feelings of exhaustion and nervous depression were doubtless the results of the vice of self-abuse. Had it not been for these consequences of indulgence in this vice, there is very little doubt but that this young woman might have passed through life without suspicion of the real cause of the non-appearance of the menses; as I am inclined to believe that the pains in her back and loins were more the result of loss of nervous energy, from excessive masturbation, than symptomatic of menstrual nusus. That the ovaries existed in this case is clear, from the presence of sexual appetite, and from the indications given of the attempt to establish menstruation, which the constitution appeared to have made at the time of puberty; a function in the performance of which the ovaries participate with the uterus. In this case, the uterus being absent an augmented activity would perhaps be induced in the endowments of the ovaries.

The last account I heard of this person was about a year since. She was then living in Sheffield, and cohabiting with a married man.

Masturbation is too often the only explanation of that chlorotic appearance the regular action of the uterus seems to abnegate. Medical men naturally shrink from bare suspicion, and will only deal with positive proofs, always most difficult to obtain in such cases; but once let the tongue be loosened by detection, and the modest motive for secrecy swept away, what a flood of disgusting relations is poured upon us, sickening to hear! Painful as it is, we cannot resist the conviction that the artificial system of education, and the mock morality now taught in some of our large educational establishments for young ladies, greatly tend to foster this vice, not only by the laxity of principles allowed, but by carrying out, almost to an insane extent, the system of outbidding one another in the scale of low charges, and the indiscriminate admission of all persons of respectable appearance or plausible connexion. This plan has admitted into schools improper characters—even kept women, who, under the denomination of "parlour boarders", have had full license and opportunity to corrupt juniors. The theory of immorality may have been "looming in the future", in the imagination of the young girl, long before she reaches school; and only at the latter place does she become acquainted with the practice of it.

2, Guildford Street, Russell Square, London, July 1853.

BIBLIOGRAPHICAL NOTICES.

ON DISEASES OF WOMEN AND OVARIAN INFLAMMATION IN RELATION TO MORBID MENSTRUATION, STERILITY, PELVIC TUMOURS, AND AFFECTIONS OF THE WOMB. By EDWARD JOHN TILT, M.D. Second edition. 8vo. pp. 276. London: 1853.

THIS volume is designated a *second edition*, whereas it is in reality a new work. The matter is greatly amplified, the arrangement is very much improved, and the composition, formerly too ornate and ambitious for the subject, is changed into a sober scientific style. The work, in its present form, is entitled to high commendation, both for its matter and its manner. It is not a treatise which claims or possesses originality; but it has the merit of being the best digest of the information which exists regarding ovarian inflammation. It is, however, something more than a compilation of other men's facts and opinions; for the author frequently expatiates, in a most instructive manner, from the abundance of his own resources. We may add, that Dr. TILT has filled, to as great an extent as it was possible, an acknowledged vacuum in our medical literature. The labours of many must, however, be devoted for years to come to supply the information which is still required, before we can be satisfied that we have learned all that is within our grasp regarding ovarian inflammation and its consequences.

Dr. Tilt's work is divided into an Introduction and twenty-five Chapters. A copious table of contents is prefixed to the volume, which gives the reader a good bird's-eye view of the subject before he commences to study it in detail; and for those who may wish to consult the book upon an emergency, there is appended an admirable alphabetical index.

In the Introduction, Dr. Tilt alludes to the defective nomenclature of the diseases of menstruation, as illustrated by the terms amenorrhœa, dysmenorrhœa, menorrhagia, leucorrhœa, and hysteria. For example, he says:

"LEUCORRHOEA stands either for—

1. Chronic catarrh of the Fallopian tubes. [*Rokitansky.*]
2. Uterine catarrh.
3. Hypersecretion of the mucous follicles of the neck of the womb in most cases. [*Tyler Smith.*]
4. Ulceration of the neck of the womb in most cases. [*H. Bennet.*]
5. Various inflammations of the vagina or external organs in most cases. [*Lisfranc.*]" (p. 2.)

The frequency of ovarian inflammation is proved by the statistics of hospital *post mortem* examination. We are reminded that—

"Mr. Pollock has shown that, out of 583 women opened at St. George's Hospital (from 1841 to 1850), 205 presented lesions in some parts of the generative apparatus, and in 116 were found the following lesions:—

"Adhesions of ovaries	-	-	13
Congestion	-	-	17
Scrofulous deposits	-	-	4
Fibrous deposits	-	-	1
Cartilaginous deposits	-	-	1
Calcareous deposits	-	-	2
Cystic tumours	-	-	51
Cancerous tumours	-	-	18
Atrophy [not senile]	-	-	8
Displacement	-	-	1

116"

The topographical anatomy of the ovarian region, and the methods of exploring the ovaries, are explained. Remarks are made upon abdominal, vaginal, and rectal exploration; and examination by the double touch and by the speculum are also considered.

Chapter I is occupied with the Theories of Menstruation.

Chapter II treats of the Natural History of Menstruation.

Chapter III contains some interesting observations on Type in Menstruation. By *remittent menstruation*, Dr.

Tilt means "that variety of menstrual derangement which is characterised by a change from the habitual type to another where the menstrual periods are brought nearer and tend to run into each other". Sulphate of quinine is often, as Dr. Tilt points out, a very valuable remedy in such cases. Alternately with this medicine, we are in the habit in such cases of giving sulphuric acid, and also gallic acid in pill with extract of henbane. The preventive treatment of remittent menstruation is thus laid down by the author:—

- "1. Strengthening of the nervous system.
2. Improvement of the blood by tonics and steel.
3. Observance of a judicious regimen during the menstrual crisis.
4. Forbidding the domestic use of purgative medicines, which frequently disturb the regularity of the menstrual type.
5. In general, marriage brings about the adoption of the normal type of menstruation, and parturition has often the same effect." (p. 54.)

Chapters iv and v treat of the Ovarian Nisus, and of the Ganglionic Symptoms of Menstruation. Did our space permit, we might make extracts from and comments upon these chapters.

Chapter vi treats of Cerebral Symptoms and their Classification. The morbid influences of the ovarian nisus upon the brain are thus classified: 1. Pain in the head; 2. Sick headache; 3. Pseudo-narcotism; 4. Hysteria; 5. Epilepsy; 6. Insanity.

By the term *Pseudo-Narcotism*, Dr. Tilt designates a group of cerebral symptoms similar to those produced on the brain by narcotic poisons, and which are familiar to practitioners. He seeks to assign these symptoms to six causes, viz., 1. Cerebral disease; 2. Plethora; 3. Anæmia; 4. Biliary derangement; 5. Toxæmic effects of retained menstruation; 6. A ganglionic nervous influence. The following paragraph is a specimen of Dr. Tilt's least careful and more dashing manner. Criticism races in before sober compilation, in place of taking its proper place in the rear.

"Struck by the fearful consequences of suddenly suppressed menstruation, producing in some cases delirium, cerebral congestion, and death, many observers, and lately Drs. Todd and Cormack, have sought to explain these effects by the toxæmic effects of the retained menstruation on the nervous system; but similar symptoms, and all the less degrees of pseudo-narcotism, are most frequent in the female before first menstruation, and after its cessation; and, as in the girl before puberty, so in the woman who has passed the climacteric, there can be no menstrual secretion to be reabsorbed: the explanation therefrom cannot stand." (p. 81.)

As no available reference is given to the writings of Drs. Todd and Cormack, we are unable to determine the passages to which Dr. Tilt alludes; but we can, nevertheless, state that Dr. Cormack speaks only of toxæmia from *non-elimination* of effete matter from the blood, and not from *re-absorption* of excreta from the blood. The paper referred to by Dr. Tilt is one probably upon Puerperal Convulsions. It has already been briefly noticed at p. 64 of the ASSOCIATION JOURNAL for January 21st; and it originally appeared in the *London Journal of Medicine* for June 1849.

Chapter vii is upon the Spinal Symptoms of Menstruation; chapter viii, upon the Critical Discharges of Menstruation; chapter ix, upon the Sanguineous Discharges of Menstruation; chapter x, upon the Mucous Discharges of Menstruation; and chapter xi, upon the Intestinal Discharges of Menstruation.

Dr. Tilt correctly remarks, that

"The critical discharge from the generative intestine is mucous as well as sanguine; that it generally constitutes the first and last part of each periodic crisis, and the first and last effort of the whole menstrual function; that it is often periodically repeated for years previous to the appearance of first menstruation, and is in some rare cases completely substituted for the sanguineous discharge. Thus, the first result of the ovarian nisus is to determine the pain; the second is to increase the habitual mucous secretion; the third is to determine the flow of blood." (p. 119.)

In chapter xii, Dr. Tilt speaks of the Influence of the Ovarian Nisus on the Cutaneous and on the Urinary Surfaces.

"If", says he, "cutaneous eruptions very seldom owe their origin to the menstrual function, during the period of its full performance, they are of frequent occurrence during the prodroma of first menstruation, and until it is regularly established. Those who attend large girls' schools know how frequently *acné* and other skin diseases appear on the face, the back, and shoulders, during that time, and how quickly they disappear when menstruation has become regular."

These observations are correct; and they harmonise well with a general remark we made when noticing, at p. 542, Dr. Neligan's book on "Diseases of the Skin", viz., "that it is monstrously absurd to speak of any appearance on the skin, except as a sign indicating a derangement of one or other of the leading functions of the body".

Chapters xiii to xxiv inclusive are devoted to Ovaritis, in its acute and subacute forms, in reference to its diagnosis, treatment, sequelæ, and statistics. A great amount of valuable matter is collected and submitted to the reader in a well arranged form. Subacute ovaritis is represented as assuming the following types, viz., the puerperal, the amenorrhæal, the dysmenorrhæal, the menorrhagic, and the hysterical. Sterility is mentioned as a common consequence of subacute ovaritis; and, by the consideration of that point, the author is led to consider inflammation of the Fallopian tubes as a cause of the same condition. He describes and condemns Dr. Tyler Smith's proposal to catheterise these passages: he doubts the possibility of performing the operation, and affirms that, if it could be performed, it would be both useless and dangerous. The chapters on ovaritis invite to lengthened commentary; but our arrears are so heavy in various departments, that we must pass on, simply commending them as deserving of study.

The xxvth and last chapter is devoted to the Pathology and Treatment of Sanguineous Pelvic Tumours. The subject is by no means exhausted, and the remarks upon diagnosis are particularly in want of additions. The information given is, however, very interesting; and the chapter, as it stands, is a good contribution towards a more extended inquiry. It is impossible satisfactorily to consider sanguineous pelvic tumours apart from other pelvic tumours: and this is a large and difficult subject which is still in much want of elucidation.

We have now rapidly run over the contents of Dr. Tilt's volume; and we hope that the indications of its value which we have given may induce many of our readers to peruse it with the deliberation which it deserves. Though the pages often sparkle with speculations, they likewise abound with telling facts and sound therapeutical data.

ON THE CONSTRUCTION AND USE OF THE MICROSCOPE. By ADOLPHE HANNOVER, M.D., Lecturer on Anatomy in the University of Copenhagen. Edited by JOHN GOODSTIR, F.R.S.E., Professor of Anatomy in the University of Edinburgh.

THE author of this work, after making some judicious preliminary remarks on vision, the different forms of lenses, and the refractive power exerted by the latter in their transmission of the rays of light, divides his work into five chapters, which successively treat of the Simple and Dioptric Compound Microscope; of the directions for the use of the latter instrument; of the Solar Lamp, Oxyhydrogen, and Photo-Electric Microscope; and of the Catoptric Compound Microscope. From this arrangement it will be seen that the method is highly judicious; inasmuch as it passes, by regular gradation, from the most simple to the more complex and difficult parts of the subject. Under each chapter the different parts of the subject appertaining to that division, are set forth with a clearness, conciseness, and precision, which cannot fail to render the work of great use to all who may choose to adopt it as their guide to the correct knowledge of the important subjects which it treats.

Chapter III deserves especial mention, as being full of practical remarks in reference to the preservation and arrangement of the microscope, illumination, the choice of magnifying powers, and the selection, preparation, observation, measurement, delineation, and preservation of objects. In short, the whole work forms a complete treatise on the construction and use of the microscope; whilst it has this special recommendation, that it conveys a vast amount of very valuable information without wearying the reader by a tedious prolixity of detail. We therefore highly recommend it to the notice of the profession, in the full expectation that it will shortly become as great a favourite in England as, we doubt not, it is upon the continent.

REPORTS OF SOCIETIES.

EPIDEMIOLOGICAL SOCIETY.

REPORT OF THE SMALL-POX AND VACCINATION COMMITTEE.

THE Report which the Small-pox and Vaccination Committee presented to the Council on the 26th March, was drawn up by them, as then stated, in consequence of a bill for the extension of vaccination having been laid before Parliament by Lord Lyttelton. It contained a review of the present state of vaccination in this and foreign countries, and concluded with an unanimous expression of opinion on the part of the Committee in favour of a compulsory enactment, and with some suggestions for the improvement of the Vaccination Extension Bill.

The Report having been adopted by the Council, copies of it were forwarded at their desire to the Secretary of State for the Home Department and to Lord Lyttelton; and it has since been printed and published by order of the House of Commons. The bill having passed through all its stages in the House of Lords, is now waiting a second reading before the House of Commons;* and as in its progress it has undergone many alterations, avowedly in consequence of the Report emanating from this committee, the committee consider that it has become their duty to examine how far these changes are in conformity with the suggestions made, and to what extent the bill in its present shape is likely to be successful in attaining the end proposed by its author,—the more general diffusion of vaccination.

To attain this great object, two things appear to the committee to be alike indispensable: a compulsory enactment, and the encouragement and stimulation of those employed to administer it.

They consider that the argument in favour of compulsory vaccination was satisfactorily established, when it was shown that the proportionate mortality from small-pox in England and Wales, where the practice is entirely voluntary, is considerably more than double what it is in any European country in which the practice is compulsory, and *ten times as great as it is in many of them*; and the committee only revert to this point for the sake of recording their satisfaction at finding that the National Vaccine Board, in their Report just presented to Parliament, are equally anxious that vaccination should be made compulsory, and renew the expression of "their conviction that, if England is to be free from the small-pox, the interposition of the legislature alone, by wise and comprehensive measures, can disarm the pestilence of its terrors, and realise the fond hopes and prayers of the friends of humanity." The committee, however, are quite as firmly convinced that any measure of compulsion will fall far short of what may reasonably be expected of it, unless encouragement be given at the same time to administrative zeal and energy. They showed in their former Report how much had been effected, and might be effected, by these alone; and they gave a most striking illustration of their importance by contrasting two provinces of the same kingdom (Belgium), subject, of course, to the same compulsory laws,—in one of which the vaccinations in proportion to the births were nearly twice as numerous as in the other.

These, then, being the essential or fundamental conditions to be kept in view in any measure for the extension of vaccination, the committee have examined the amended bill of Lord Lyttelton with reference to them, and beg to observe:

1. *In reference to compulsion.* That the clause for this purpose (clause viii) is simple and direct, and likely, to a large extent, to be efficacious for its object; but that it would have been more so, had the suggestion of the committee been adopted, and had it been made the duty of some special officer in every union or district, to proceed against persons not complying with its terms.

2. *In reference to encouragement.* That not only does the bill hold out no encouragement to stimulate the zeal and activity of those upon whom it will mainly devolve to carry it into execution, but that by imposing upon them additional duties, while at the same time it expressly provides that they shall receive no remuneration for these duties, it makes it their present interest to oppose the bill in its passage through the legislature, and will disincline them, should it eventually become the law of the land, from rendering that active and spirited co-operation, which the committee have pointed out as essential for the attainment of the object sought. It would need no laboured argument to show, that on the medical men employed as public vaccinators throughout the kingdom, it will depend in a great measure whether the act shall be successful in its operation or not. If they be interested in its success, the universal vaccination of the people of this kingdom is not far distant; if, on the other hand, they be indifferent and apathetic, still more if they be hostile, this or any other measure will fail to a great extent to secure its end; and the real alternative before the legislature is this—whether they will permit some thousands of deaths from small-pox to take place yearly, or whether, by a wise and just expenditure of the public funds, they will evince their earnestness to eradicate this scourge, so disgraceful to the empire and to the age in which we live.

In their former Report, the committee exhibited some of the evils resulting from the present system of medical remuneration, as regards the practice of vaccination. They showed that the average sum paid for each successful case in England and Wales was less than eighteen-pence—a sum so inadequate that in many districts it was the custom to delay vaccination until a sufficient number of cases had accumulated to make it worth the while of the medical practitioner to perform the operation. This serious evil will, to a certain extent, be prevented by the enactment, that all vaccinations shall take place within a given time after birth; but additional trouble will thus be so far imposed on the vaccinator, and this of itself should constitute a ground for increase of remuneration.

Another and great evil of so low a scale of payment has been found to be, that the vaccinator having performed the operation has, in many instances, considered his task as accomplished, and has taken but little pains to ensure the inspection of the person vaccinated. Yet such inspection is alike necessary for ascertaining that the vaccination has taken proper effect, and for keeping up the supply of lymph. It should be one of the first duties of the legislature so to provide for the remuneration of the vaccinator, as to enable him to afford the requisite time, and to make it worth his while to follow each case to its own home (provided it be not brought to the station); so that in no instance should there be any doubt as to the success of the operation, nor any opportunity lost of maintaining a proper stock of good healthy lymph.

But if the payment hitherto given has been found insufficient to secure the attendance thus pointed out as absolutely indispensable, still less can it be expected that the additional duties imposed by the act will be efficiently discharged, unless additional remuneration be afforded. By the third clause the vaccinator will have, besides keeping the books and registers with which he is already furnished, to give two certificates *in every case*—one to the parents, the other to be sent to the registrar; and by the fourth clause, he will be required to examine into the state of health of persons submitted to him for the operation, and to certify thereupon, if they be not then fit for it; and this examination and certificate (which are as much professional acts, and involve as much knowledge and judgment, as vaccination itself) may have to be renewed an indefinite number of times. It is only those who have had such duties to perform who can understand the time they require and the trouble they give. The labour they imply ought not to be unrewarded; and the committee are quite at a loss to understand why a fee should be given to the registrar for each certificate he may give, or entry he may make, and yet be withheld from the medical man for the far more important duties which he has to perform.

Independently of the mischief which has arisen from the insufficient remuneration to the public vaccinators, there are other evils resulting from the mode in which that remuneration is given. Under the present system, payment is made by the

* It has, since this Report was drawn up, been read a second time.

Boards of Guardians—half from the consolidated fund, and half out of the poor's rate.

One serious evil was shown in the Report to be that some Boards, from a mistaken notion of economy, and desire to keep down the rates, actually discourage the efforts of the public vaccinators, and remonstrate with them if the number of vaccinations be large.

Another, to which the Committee did not then advert, appears to be this—that poor law medical relief, and public vaccination, being administered by the same board, and *paid for out of the same funds*, private practitioners, who would willingly be vaccinators under a national system, but who do not desire to be considered as in the employment of the Boards of Guardians, have abstained from taking the office, and thus the number of public vaccinators has been unduly limited.

The first of these evils would be entirely, and the second partially obviated, if the payment for vaccinations were made altogether out of the consolidated fund.

The most effectual remedy, indeed, for all the evils which have been pointed out would be to disconnect public vaccination from the poor law administration, and to place it under the superintendence of competent persons (as in other countries) whose sole duty should be the organizing and carrying out a system for the entire vaccination of the people. But if the legislature should be unwilling at the present moment to make this fundamental, and, as the Committee believe, most essential and ultimately indispensable change, it will yet be a great improvement on the present system that the rate of remuneration should forthwith be increased, and that payment should be made out of the consolidated fund.

To give effect to these suggestions it will be necessary that a short clause be introduced between clauses II and III, requiring the parents or guardians to return with the child on the eighth day after the operation, that the arm may be inspected and the certificate of successful vaccination given: that the fifth clause be omitted altogether; and that a clause be added fixing a minimum fee for the operation, and regulating the manner in which the fee shall be paid.

There are some other points to which the Committee have to advert. They find that clause II of the Bill is still so worded as to interfere with the rights of private practitioners; an obligation being thereby imposed by the legislature on every qualified medical practitioner to vaccinate *any* child which may be brought to him. Such is undoubtedly the effect of the clause, though the Committee know that this is far from the intention of the author and promoters of the Bill; and they suggest that the object of the clause will be attained, and every objection obviated, if all the words from the end of the thirty-fourth line be omitted, and the following substituted:—"for the purpose of being vaccinated (unless he shall have been previously vaccinated by some other qualified medical practitioner, and the vaccination duly certified), and the said medical officer or practitioner, so appointed, shall, and he is hereby required thereupon, or as soon after as it may conveniently and properly be done, to vaccinate the said child."

The Committee regret to observe that no provision is made for the vaccination of children immigrating into this country, for the case of the removal of a child from the district in which he is born to some other district previous to the time till which vaccination may be deferred, for the exemption of children and persons who have had small-pox, nor for securing more frequent periodical returns of the numbers vaccinated to the central authorities.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

JUNE 15TH, 1853.

JAMES Y. SIMPSON, M.D., F.R.S.E., in the Chair.

ANCHYLOSIS OF THE ELBOW-JOINT REMEDIED BY EXCISION.
BY JAMES SYME, ESQ., F.R.S.E.

Mr. SYME placed before the Society what he believed to be the first case, in which anchylosis of the elbow had been remedied by removal of the ends of the bones involved. The satisfactory

results of this operation, as performed for caries, had frequently suggested the expediency of extending its field of usefulness to cases in which the elbow had been rendered stiff by the effects of injury or disease; and four years ago a case presented itself, so urgently requiring relief, as apparently to warrant even a doubtful experiment. The patient was a young man who came from one of the most remote highland glens, with both of his arms stiff in the straight position; the right elbow-joint being nearly, the left completely destitute of motion. The former had suffered a dislocation of the fore-arm backwards, which from being overlooked, remained unreduced; and the latter had been fractured through the condyles of the humerus. The state of helplessness thus resulting was extreme—rendering the patient unable to dress and undress, eat his food, perform his ablutions, or, in short, perform any service whatever either for himself or his neighbours. The left arm, being completely rigid, was chosen for operation, and the Society would now perceive that it had been rendered perfect in regard to form, mobility, and strength. The operation was performed in the Royal Infirmary, and the patient was now attending the normal school, to qualify himself for the duties of a practical teacher.

Dr. MACKENZIE said he had performed the *same operation* in a similar case some time ago, but with a less favourable result than in Mr. Syme's case. The elbow in this case had been ankylosed nearly in the straight position, which rendered the limb comparatively useless. It was now, since the operation, at a right angle, which enabled the patient to bring her hand up to her mouth or to the back of the head. The degree of motion, however, at the elbow was very limited. He would be glad to know how it was to be explained, that the amount of motion after excision of the elbow varied so much in different cases. In some cases in which he (Dr. M.) had performed the operation of excision of the elbow-joint, the amount of mobility (like the present case shown by Mr. Syme) was nearly natural, while in others the new joint was but slightly moveable, and this without any difference in the operation or after treatment, or in the extent of bone removed.

Mr. SYME replied that he could only answer for the results of his own practice, and that the mobility of the new joint depended on the operation being properly performed.

Dr. MACKENZIE said that this explanation was not very satisfactory. Mr. Syme must be aware of the facts he had mentioned. He (Dr. M.) had enjoyed extensive opportunities of seeing Mr. Syme's mode of operating and after treatment, and it differed in no particular from his own. He had asked the question solely with the view of eliciting information.

ANATOMICAL PREPARATIONS. BY JOHN GOODSIR, ESQ.

Professor GOODSIR described and illustrated a new mode of closing bottles containing wet preparations. The preparation-jars, (which were invented and manufactured by Mr. Stevenson, philosophical instrument maker, 9, Lothian Street, Edinburgh,) resembled in form the ordinary cylindrical jars at present in use, but had no lip, the glass being rather thicker at the top of the jars than elsewhere, and being carefully ground flat, so as to receive a circular slide of smooth plate glass, adapted in size to the mouth of the jar. When the jar was filled with fluid, and the plate glass cover accurately adapted, it was found that it could be inverted without the escape even of a single drop; and all that was necessary to maintain this amount of security was to surround the top of the jar by a metal ring, so as to prevent lateral displacement of the slide. The brass ring, as adapted by Mr. Stevenson, rendered the whole apparatus exceedingly elegant. The preparations were suspended by a piece of whale-bone, fitting into two notches on the internal surface of the jar, about three-eighths of an inch below the top; this arrangement displayed them to great advantage, the light being let in on all sides; while, on the other hand, it did not in any degree interfere with the perfect closure of the jar.

A preparation thus adjusted, might at any time be easily removed and replaced in a few minutes. It might, therefore, be without difficulty covered in while still recent, and again at every change of spirit. A great deal of spirit would thus be saved, which is usually lost by evaporation during the numerous changes required by most wet preparations before they are finally covered in. When permanently enclosed, a little thick luting might be placed around the mouth of the jar beneath the metal ring, and thus all access of air would be prevented.

Mr. Goodsir, in the course of his remarks, observed that the method hitherto followed in Edinburgh of covering preparation-jars by two layers of moist decomposing bladder with an intermediate portion of sheet-tin, was, in his opinion, almost as perfect as could reasonably be looked for, and he believed it would

still continue to be best adapted for very large collections. On the other hand, the time and trouble saved by the new method, and its comparative simplicity and cleanliness in the manipulations, as well as the elegant appearance of the result, would make it preferable for private collections. In point of expense he believed that the new method would prove the cheaper of the two, as it added, on an average, not more than one shilling to the expense of the preparation-jar, while the saving in trouble and in spirit would be very great.

The only objection that could be urged against the new method was that it did not allow for changes of temperature, and the consequent expansion and contraction of the fluid. Mr. Sheldon, who had in London pursued a somewhat similar method of enclosing wet preparations, covered the plate glass with bladder; but this method, though apparently very perfect, was found to lead to bursting of the jars under the effect of increased temperature. The principle of the method now proposed was to avoid fixing the top to such an extent as to prevent expansion of the fluid; and by leaving a little air in the jar, all inconvenience and risk would be avoided.

Dr. W. T. GAIRDNER had made a practical trial of the method recommended by Mr. Goodsir, having employed it for the last two months in enclosing a number of preparations. He was convinced that it would fulfil the expectations entertained of it by Mr. Goodsir, and had determined to adopt it in future, although he had found that it was almost impossible to avoid the escape of a very little fluid under increase of temperature, and he believed that any mode of removing this objection and rendering the process theoretically perfect, would endanger the preparation-jars. He had found it convenient, in covering the jars, to use the preservative fluid slightly warmed (to 90° or 95° F.) In this way the glass top was firmly pressed down on the jar from the first, and a vacuum was created, which, although it afterwards filled with air to a certain extent through the slight imperfections of the fitting, maintained for a long time the balance of pressure on the exterior. He believed that external luting would probably be found of no use, as this small amount of imperfection was absolutely necessary to safety, and any luting, not firm enough to endanger the jar by fixing the top, would be displaced so soon as there was any material pressure in either direction. The perfect cleanliness and simplicity of the method, and the ease with which preparations could be removed and replaced, were its great advantages.

Dr. BALFOUR referred to the mode of covering preparations by Mr. Ball, of Cambridge, by glass and India rubber. He intended, however, to give the present method a trial.

STATISTICS OF DEATHS AMONG THE ASSURED. BY ROBERT CHRISTISON, M.D.

The abstract is incorporated with that of Dr. Begbie's paper.

JUNE 29TH, 1853.

J. Y. SIMPSON, M.D., in the Chair.

STATISTICS OF DEATHS AMONG THE ASSURED. BY JAMES BEGBIE, M.D.

Drs. CHRISTISON and BEGBIE laid before the society the substance of reports which they had drawn up on the above subject, for the use of the life offices with which they are respectively connected.* The communications were of considerable length, and contained a great number of numerical details.

The report of Dr. Christison was chiefly directed to the investigation of the causes of death as bearing on the business of life assurance; that of Dr. Begbie, while embracing this view of the subject, entered also more into strictly medical detail, for which the large experience of the Scottish Widows' Fund (embracing considerably more than 1000 deaths) afforded a sufficient basis. Both reports were full of matter interesting to every medical practitioner. A large proportion of deaths in both offices had been caused by epidemic fever; and both reports testified to the fact, that the typhus of this country is not only a frequent cause of death, but that it appears to select its victims very frequently from the most unexceptionable lives of the community, and to terminate these abruptly at the period of greatest activity. The same may be said of cholera, which, during the last epidemic visitation, seems to have fallen heavily upon the assured in middle life. Next to fever, as a source of loss to the community, stands phthisis and tubercular disease, which likewise finds its victims to a great extent before the middle period of life. It was remarked that, in the report of the Scottish Widows' Fund, the number of deaths from phthisis after the age of 40 appeared larger than is usually observed in mortality lists,

or in the general experience of medical men. In apoplexy and palsy, on the other hand, the returns at the different ages corresponded closely with the table given by Rochoux. An accurate analysis of the deaths from these causes showed that, whereas in phthisis most of the lives had, at the period of acceptance, presented some character which might have led to their being considered doubtful, this was not the case in apoplexy. The investigation, therefore, of the premonitory signs of the apoplectic tendency was pointed out as a desideratum by the authors of the papers.

The discussion which followed the reading of Dr. Begbie's paper was of a rather desultory and conversational character.

Dr. OMOND adverted to the general impression, that the more rigorous examinations of the vital organs now in use had given rise to a greater number of refusals than formerly on the part of insurance companies. He said that, in some diseases at least, this was not the case; and referred to hæmoptysis, as an affection which would have been uniformly rejected twenty years ago, but which, in certain select cases, would now be admitted to insurance at a slightly increased premium.

Mr. SYME referred to one probable effect of the information afforded by these reports. It was possible that the evident attention paid by insurance companies to hereditary causes of disease might effect a reform which political economists and philosophers had long attempted in vain; and that the relations of marriage might be regulated to a greater extent than hitherto, by a consideration of the inexpediency of transmitting to succeeding generations hereditary peculiarities, which might exclude them from the benefits of life assurance.

Dr. W. T. GAIRDNER said that, although insurance companies were quite warranted in taking the safe side of a doubtful case, he believed the tendency of the present day was to overrate the importance of hereditary influences in relation to some kinds of diseases. The rule, for instance, established in some companies, that two deaths from phthisical disease in a family excluded its remaining members from the benefits of assurance, could not be very strictly adhered to without causing great and unnecessary hardship. Judging from various statistical data, it appeared to Dr. G. that, in a moderately large family, two deaths from tubercular disease would not necessarily imply a very high average, and could not be held as in general affording such proof of a marked hereditary taint as would justify the rejection of an otherwise unexceptionable life.

Dr. CHRISTISON differed from Dr. W. T. Gairdner in his estimate of the importance of the rule alluded to, and defended the practice of the insurance companies, which, he said, admitted of many exceptions to that rule, and could by no means be justly accused of erring on the side of too great strictness.

Considerable discussion followed, in which Drs. Begbie, Christison, Alex. Wood, and W. T. Gairdner, took part.

EDITOR'S LETTER BOX.

MEDICAL ETHICS.

LETTER FROM W. H. MICHAEL, ESQ., TO THE EDITOR.

SIR,—I shall be glad if you will announce in your next number, that it is my intention to move at the Annual Meeting of the Association at Swansea, "That in the opinion of this meeting it is desirable that a code of laws for the guidance of the members in all matters appertaining to professional ethics should be adopted, and that a committee consisting of the following gentlemen" [to be then selected] "be appointed to deliberate upon the subject, and report to the next Annual Meeting of the Association."

Entertaining a strong opinion as to the desirability of this resolution being carried into effect, and hoping to have your valuable cooperation and support, I am, etc.,

W. H. MICHAEL.

Swansea, July 12th, 1853.

THE BRANCHES OF THE ASSOCIATION.

LETTER FROM JOHN MCINTYRE, M.D., TO THE EDITOR.

SIR,—The perusal of the gratifying reports of the different Branches, which have recently appeared in the Journal, induces me to offer a few remarks on the organization of our body.

The locality in which I reside is so situated, as not (so far as I can find) to be included in any of the existing Branches. I

* The Standard Life Assurance Company and the Scottish Widows' Fund.

am thus deprived of any opportunity of meeting with my fellow practitioners, except at the General Meeting. I very much regret being so circumstanced, as I am fully alive to the many advantages, as well moral, as social and professional, that accrue from frequent intercourse between the members.

I am not aware whether any particular plan was adopted in the formation of the existing branches in the first instance; or whether they accidentally originated wherever a certain number of members resided near to each other. If there was not, it seems to me desirable, with our swelling numbers, that some fixed plan should be adopted; and no one appears so little objectionable as a geographical. England and Scotland might be divided throughout their length and breadth into districts, each of which would assume active operations where a stated number of the resident practitioners had joined our ranks.

It seems to me also that the great objects of our body would be more effectually promoted were we to have meetings more frequently betwixt the members; but this, considering our position with the community, and the difficulty we have in leaving our homes for any length of time, is impossible, if we have forty or fifty miles to travel. I would therefore suggest to the members, for their consideration before the annual meeting, the propriety of having *local*, as well as *district Branches*.

Each *local* branch might comprise an area about twenty miles, meet once a month, and have a central and fixed place of meeting. Its business should comprise the discussion of questions affecting the sanitary condition of the people; the reading of medical papers and cases; the taking cognizance of all irregularities in practice; and the private hearing of, and adjudicating upon, all professional differences and peccadilloes.

The Council of the *district* Branch should be composed of representatives from the local branches—chosen, either in rotation, by ballot, or the suffrages of their fellows—who would carry up the report of the discussions of their several bodies for the opinion, or judgment it might be, of the higher Assembly; and assist in the transaction of the other business of the Branch.

The General Executive should be composed also of representatives from the various local branches; be considered the highest court of appeal in matters medical; receive the results of scientific investigations, and all discussions of the Branches; canvass the correctness of the one, and the justness of the other; issue reports of its transactions through its accredited organ, and be, in fact, a representative council for conducting the business of the Association. The Annual Meetings of the Parent Association, I mean of course to take place, as at present, at the principal towns of the United Kingdom.

With this arrangement the whole country would in time be brought within reach of our operations. We should present to view an organization whose highest objects and greatest efforts were for the welfare of humanity; we should command the attention and the ear of the legislature in all matters connected with the public health; we should be in a position to demand the representation of our body in the councils of the nation, by members of the profession; and be thereby more likely to witness a satisfactory adjustment of all matters connected with that *questio vexata*—Medical Reform.

I am, etc.,

JOHN MCINTYRE, M.D.

Odiham, July 18th, 1858.

ASSURANCE COMPANIES AND THEIR TRICKS.

LETTER TO THE EDITOR.

SIR,—There is a trick of the assurance companies, which I wish you would expose, and warn medical men from falling victims to. I do not think that it has yet been noticed: perhaps it is a new one.

The trick referred to is sending the schedule of the *private friend* to the medical man without a fee. Whenever a man, wishing to insure, says he has never required to employ a medical man, the agent asks him if he is *acquainted* with any. He very likely names the family attendant, and the latter receives a schedule to fill up as the private friend of the former.

This has been done to myself, on two occasions, by different offices; and a third instance has come under my notice as medical referee of a third company: so that in this town there are at least three offices in the practice of this shabbiness.

When I was referred to, I took no notice of the application. Others are not so decided; for as referee I have this very day received a schedule filled up by an M.D., as private friend, and of course no other medical certificate was sent me.

The dilemma is, either to give medical information without a fee, or to refuse to act as private friend to one whose family the practitioner attends, and thus to risk giving offence in that quarter. I need not lengthen my letter by any remarks: the bearings of the trick are obvious enough. I am, etc.,

SOCRUS.

June 20th, 1853.

TO CORRESPONDENTS. We are still unable to publish the letters, on various subjects, now in type, and to which we formerly referred. We still continue to receive letters upon *Sunday observance*, several of which, on both sides of the question, treat it theologically, and therefore in a way not suited to the pages of a medical journal. We have said all that is at present necessary on the subject; and we shall not therefore do more than publish those letters which we formerly named, when we can do so conveniently. In reply to *Dr. Simpson's Letter to Dr. Meigs*, we have received several communications; and some of them we intend to publish with as little delay as possible. EDITOR.

NEWS AND TOPICS OF THE DAY.

CHARING CROSS HOSPITAL SCHOOL OF MEDICINE.

A hot war has been raging for some time past between the Managers of this institution and one of the Lecturers, Dr. Edward Smith. The disclosures which have been made show too plainly that medical teaching in a recognised metropolitan school is sometimes at least an occupation which brings with it neither honour nor emolument. We trust, however, that good may result from what has transpired. Already, a private quarrel seems to promise a public good. The following letter was addressed by the Secretary of the College of Surgeons to a member of the medical profession, in reply to his inquiries. We reprint it from the *Lancet* of July 23rd:—

"Royal College of Surgeons, July 1853.

"SIR,—In reply to your inquiry, whether the Charing Cross Hospital Medical School is now recognised by the College, I have to acquaint you that the Court of Examiners of this College have found it necessary to direct a visitation of the said school, but have not come to any decision on the question of its continued recognition. If the additions and alterations which the Court of Examiners think necessary to the efficiency of the school should be completed before the beginning of the ensuing winter season, the recognition will be continued. In the meantime, the Council has directed its removal from the list of schools from which certificates of the professional education of candidates for the fellowship and membership of the College will be received for the year commencing the 1st of August next.

"I am, sir, your most obedient servant,

"Edward Hart Vinen, Esq.

EDW. BELFOUR, Secretary."

QUEEN'S UNIVERSITY, IRELAND. The Senate have appointed the following Examiners in the Medical Department for the ensuing year:—*Chemistry*: Edmund Ronalds, Ph.D., Professor, Queen's College, Galway. *Anatomy and Physiology*: Charles Croker King, M.D., Professor, Queen's College, Galway. *Zoology and Botany*: George Dickie, M.D., Professor, Queen's College, Belfast. *Midwifery*: John Banks, M.D., King's Professor of Physic. *Surgery*: James G. Hughes, M.D., Fellow of the Royal College of Surgeons, Ireland. *Materia Medica, Pharmacology, and Medical Jurisprudence*: Aquila Smith, M.D., V.P. and Censor, King and Queen's College of Physicians, Examiner in *Materia Medica and Pharmacy*, T.C.D. *Midwifery and Diseases of Women and Children*: Henry L. Dwyer, A.M., M.D., Fellow of the King and Queen's College of Physicians.

SIR ASTLEY COOPER'S CLINICAL PRIZE. The prize of £300 has just been awarded to Henry Grey, Esq., of St. George's Hospital, for his Essay on the Spleen. The Council has offered to print the essay, at its own cost.

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London: or to the office of the Journal. Letters requiring immediate attention and revised proofs ought invariably to be sent to Putney.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XXXI.

LONDON: FRIDAY EVENING, AUGUST 5, 1853.

NEW SERIES.

LAMERT *alias* CURTIS VERSUS DAWSON, FOR LIBEL.

MR. JUSTICE MAULE and a Leicester jury have had the disagreeable duty of sitting to arbitrate on one of the most disgraceful trials for libel that ever was listened to or recorded. The reporter of the trial tells us, that LAMERT, the plaintiff, is a man practising in London, under the assumed name of Curtis, in a certain department, but is not a qualified practitioner of medicine or surgery; and that DAWSON is also a person practising in London in a certain department, but is a member of the Colleges of Physicians and Surgeons. Dawson is the author of a book in which something is said calculated, it is alleged, to do injury to Lamert *alias* Curtis. These are briefly the circumstances under which Dawson is called upon to defend himself for libel. The trial, as reported in the *Times*, appears in a subsequent page.

In our ignorance of law, we had fancied that such a trial for libel could not have been permitted. A libel is a statement which is calculated to do injury to an individual in some particular way; to do injury to his character morally, or to do him injury in the practice of some lawful pursuit or business. In the trial before us, it was proved that the plaintiff was not following any lawful calling; on the contrary, that he was acting in downright and direct opposition to the law; and the law would no more receive from such a man skilled evidence having reference to that department which he assumes, than it would from a shoe-black or a razor grinder: and yet this same law allows itself to defend this plaintiff against a libel calculated to do him injury in a department or business carried on contrary to legal statute, and sustained only by official apathy.

It is not pleasant to contemplate eminent legal gentlemen defending, for a handful of gold, a nasty character, who practises his destructive trade in opposition to the laws of the realm, and who is notoriously the disseminator, at an enormous outlay of money, of filthy books and demoralising advertisements.

The report of this trial conveys an admonition to our Colleges. If we wish to hold on in the path of duty and of honour, it is necessary for us to disown every one who disgraces his great vocation. Let the Colleges of Physicians and Surgeons, whose names have been so much polluted by the trial at Leicester, take notice of the conduct of persons who for the present shall be nameless. Let us all, with one accord, repudiate vile men who fill their purses by unscrupulously lowering the character of their professional brethren, and by resorting to unprincipled puffing of their

own assumed integrity and superior skill. "If", said brave old Sir Humphrey Gilbert, "if, through pleasure, selfishness, or idleness, we purchase shame, the pleasure vanisheth, but the shame abideth for ever."

Join with us, then, fellow associates, in adopting these simple yet powerful words, and in striving to regulate our conduct, as individuals and as members of medical colleges, under a deep conviction of the truth which the words convey.

MEDICAL WITNESSES IN RELATION TO THE DIFFERENT SYSTEMS OF CRIMINAL JURISPRUDENCE OF ENGLAND AND OF SCOTLAND.

WE formerly (June 2nd, p. 478) had occasion to advert to the superiority of the Scottish system of criminal law, under which processes are instituted by the Crown authorities, and not by private individuals bound over to prosecute, as is the case in England. We remarked that "the want of a public prosecutor is a glaring defect in the criminal jurisprudence of England, which ought at once to be remedied". We had chiefly in view, when we made that observation, the notorious frequency with which justice miscarries in England, as compared with Scotland, apparently in consequence of the more clumsy and more cumbrous machinery of the English law. We have now to direct attention to another mischief, which arises from the same cause,—a hardship which may occasionally press upon any member of the community, but which is liable to occur most frequently to members of our profession. We refer to the astounding fact, that, when a prosecution breaks down in its preliminary stages, medical witnesses may have no legal claim to remuneration, even though they may have been taken for days together from their practice, and subjected to hotel and travelling expenses. They may not only be unable legally to claim any compensation for their loss of time, but they may even be unable to obtain restitution of their compulsory outlay of money.

We are not speaking of hypothetical grievances: we have before us a newspaper report of a case in point, which was discussed at the Glamorganshire Quarter Sessions, on the 27th of June last. A sketch of this discussion will do more to enlighten our readers upon the glaring defect in English criminal law to which we have now adverted, than any dissertation which we could frame upon the subject. Apposite facts, when simply told, are always the most cogent arguments against oppression.

"Mr. FRANKLEN called the attention of the court to a case, important to every magistrate present. In March last

he chanced to be the Chairman of the day at the Bridgend Petty Sessions. A complaint was made on that day by Edward Jones against David Richards, for an assault. The magistrates came to the conclusion that an aggravated assault had been perpetrated, inasmuch as the complainant's jaw had been broken by a stone, and the defendant had waylaid him for the purpose of assaulting him. David Richards was therefore committed for trial at the Quarter Sessions; and to secure the ends of public justice, the magistrates bound over Edward Jones, and Mr. Phillips, a surgeon, to give evidence. David Richards was indicted at the Easter Quarter Sessions, at Swansea. A true bill was found against him by the grand jury. He was tried before a petty jury and acquitted. The costs of the prosecution were not allowed by the court; the result of which was, that the justices' clerk, the police officers, and the surgeon, who were witnesses in the case, were all unpaid for their attendance at Swansea, and their other services.

"The CHAIRMAN said, that although a jury might acquit a prisoner, the court might think the verdict contrary to evidence, and would not refuse the costs; but, in the case alluded to by Mr. Franklen, the party who prosecuted for an assault had himself been convicted of an assault on the party committed for trial, on the very same night.

"Mr. FRANKLEN said, that by the refusal of costs in the case referred to, the sufferers were the justices' clerk, the police officers, who were witnesses, and the surgeon,—persons who were perfectly innocent of those charges, and had been bound over in heavy penalties to attend and give evidence.

"Mr. H. A. BRUCE said, that costs might be refused on two separate grounds. First, on the ground that the case ought to have been summarily disposed of by the magistrates; and secondly, on the evidence adduced, not before the magistrates, but before the court, which would lead the Chairman to consider that the case for the prosecution did not justify the payment of costs out of the funds of the county. The costs were refused, not because the Chairman found fault with the magistrates for committing the man for trial, but because the prosecutor was not entitled to bring that case into this court. No doubt the decision not to allow costs was pecuniary loss to innocent witnesses; but he did not know what other means the court had of showing disapprobation of the conduct of a prosecutor than by disallowing the costs.

"Mr. FRANKLEN said, it was a very painful position for the magistrates to be in, that of being the means of fining a gentleman many pounds, in addition to his loss of time, by requiring him to perform a public duty. The medical gentleman was perfectly innocent, and was bound over in heavy penalties to attend.

"Mr. H. A. BRUCE said, that the decision had been given by their Chairman, who was assisted by one of the most judicious and able magistrates in the county; and they ought to receive it as a decision properly arrived at.

"Mr. BRUCE PRYCE had seen costs applied for, in cases where the court was not able to award them. Were there no means at the disposal of the magistrates, by which the costs of the surgeon might be paid, as he was bound over by the magistrates? He (Mr. Bruce Pryce) thought they were right in refusing costs; but, at the same time, it was very hard on witnesses to lose so much time, and yet not be paid.

"A MAGISTRATE asked whether the witnesses could not proceed against the prosecutor for payment?

"Mr. FRANKLEN said that the prosecutor was a pauper, or very little better."

Is it possible to read the above discussion, and refuse to allow that the machinery of English criminal law requires a radical reform, and that the members of the medical profession, as a body, as well as in their relation of citizens, are called upon to exert themselves to promote this end? The injustice inflicted upon Mr. Phillips demands redress: and it is an injustice which may be inflicted any day, upon any of us. Unrepresented as is our profession in Parliament, we cannot reasonably be sanguine as to speedy success crowning our exertions in any cause; but we can console ourselves by reflecting that, in this free country, the persevering agitation of a real grievance uniformly paves the way for its ultimate redress. It is this conviction which encourages us to remonstrate whenever we learn that the rights of the profession have been violated; even though we are well aware that the ear of power is listless, unwilling, and deaf to our complaints.

POSTPONEMENT OF THE VACCINATION EXTENSION BILL, AND ITS GREAT IMPROVEMENT IN COMMITTEE.

We have printed at p. 696, three new clauses which have been introduced into the Vaccination Bill, in its progress through Committee. They undoubtedly improve the Bill very much. Some of its more objectionable parts have also been altered, in deference to the suggestions of the Epidemiological Society. The Bill, however, is still open to criticism; and it is likely to be still farther improved by postponement for another year.

In a subsequent page will be found a short account of an interview between a deputation from the Metropolitan Counties Branch of the Association and Lord Palmerston, the Home Secretary. Lord Palmerston readily admitted that there were good reasons for delay; and for the present, perhaps, the danger of a mischievous Vaccination Act is averted. It remains for the profession, and in particular for the Provincial Medical and Surgical Association, to make known their opinions before another session of Parliament commences. *The best machinery for extending efficient vaccination is the problem which has to be solved.* Many helps to a right solution have already been published in this Journal, and to them we refer for ample information.

THE SWANSEA MEETING.

Our number for the 19th inst. will contain a full report of the proceedings at Swansea, on the 10th and 11th inst. If gentlemen who move resolutions, or propose committees, will have the kindness at once to place distinctly written duplicates of their motions in the hands of our reporter, that accuracy will be obtained which could in no other way be secured.

ORIGINAL COMMUNICATIONS.

CASES IN OPHTHALMIC PRACTICE.

By WHITE COOPER, F.R.C.S., Ophthalmic Surgeon to St. Mary's Hospital, etc.

CASE I. ENLARGEMENT OF THE EYEBALL FROM INJURY: EFFECTS PRODUCED BY A SUBSEQUENT BLOW: EXCISION OF THE FRONT OF THE EYE. James Cooper, aged twelve, was admitted into the male eye ward of St. Mary's Hospital, October 1st, 1852. He was said to have enjoyed good health until five years and a half previously, when his left eye was accidentally scratched with a fragment of glass. This was followed by total loss of vision, but without much pain until the expiration of three months, when the eye became painful, and began to enlarge. It was then treated with leeches, blisters, etc., for about six weeks; the pain subsided, but the globe continued enlarged. He had since complained of pain in it from time to time. Seven days before his admission the eye was struck by a potatoe thrown by another boy, which caused it to burst and to bleed very profusely. Ever since he had suffered excruciating pain, and the eye had remained in a state of inflammation.

The lad was greatly emaciated, of a pale strumous aspect; light-haired, and with bloodless lips. He lay constantly on the bed, with his face buried in the pillows. The left eyelid was of a dusky purplish hue, and traversed by many tortuous veins. The eyeball was considerably enlarged, and the sclerotic was of a deep brick-dust colour. All traces of the cornea had disappeared; and its place was occupied by a yellowish brown mass, having a deep ulcerated spot nearly half an inch in length, and two lines in width, extending down its inner side; from this there flowed a sanious offensive discharge. The patient complained of paroxysms of severe lancinating pain.

He was ordered to take two grains of hydrargyrum cum creta, with four grains of the potassio-tartrate of iron, thrice daily: the eye was directed to be kept moistened with a lotion of half an ounce of liquor sodæ chlorinatæ in ten ounces of water.

This treatment was continued for twelve days, with some advantage, as the pain diminished in intensity, and the general swelling was rather lessened. A white sloughy mass now occupied the place of the cornea, and the discharge was considerable. The case was, at this juncture, seen by several of my colleagues, and by Mr. Hodgson. A difference of opinion existed as to the precise nature of the morbid change, but all agreed that it was proper to endeavour to afford relief by operation, as the lad's general health was failing rapidly, and the prospects of improvement from palliative or medicinal measures were very slight.

It was determined, therefore, to slice off the mass occupying the front of the eye. If the contents of the globe were fluid, they would be thereby evacuated, and the eye would collapse. If, on the contrary, the disease appeared to be of a malignant character, the organ should be forthwith extirpated.

On the 13th October, the lad was placed under the influence of chloroform; and, with a long cataract knife, the mass occupying the front of the eye, including the ulcerated fissure, was fairly sliced off. Contrary to expectation, there was very little bleeding; but the eyeball was found to be filled with a tough mass, there being no trace of either lens or vitreous humour. Portions of the mass were immediately submitted to the microscope, and presented a fibrinous appearance, with great numbers of crystals of hæmatine dispersed through it. No definite cellular structure could be made out; and certainly no traces of malignant disease. It seemed, in fact, as if the globe was filled with the remains of a large blood clot. This rendered further proceedings unnecessary. The eyelids were closed with strips of plaster; and cold wet bandages ordered to be applied.

From the time of the operation, the relief was most marked; all pain ceased, the lad slept well, and rapidly recovered his appetite and spirits. On the third day after the operation, the eyelids had assumed a natural appearance, and healthy granulations were seen springing from the surface of the wound. Iron and cod liver oil were prescribed; and, on the tenth day after the removal of the mass, the wound was found to have healed kindly, and the remains of the globe to be perfectly free from irritation, forming an excellent stump for an artificial eye.

CASE II. NEURALGIA OF THE EYE FROM MECHANICAL IRRITATION: OPERATION: RECOVERY. W. W., aged 22, was admitted into the male ophthalmic ward of St. Mary's Hospital, on June 14th, 1853. When eleven years of age, he had received a violent blow on the right eye, which discoloured it, but was not at the time followed by inflammation. The eye speedily resumed its natural appearance, under the application of the popular remedy of raw beef. Three months afterwards, however, inflammation attacked the organ, and was speedily attended with ulceration, which penetrated through the cornea, causing adhesion of the entire circle of the pupil, and subsequently giving rise to a dense leucomatous projecting cicatrix, occupying two-thirds of the cornea. After this, the eye suffered from repeated attacks of pustular ophthalmia; and, in 1850, violent neuralgic pain set in, which, with the exception of one fortnight's reprieve, continued constantly, though varying in degree, until the period of his application. He had sought relief at many institutions in town and country, and had undergone a great variety of treatment, including the frequent application of caustics, without deriving the least advantage.

He was pale, emaciated, and evidently worn down with suffering. Every attempt to face the light, or to open the eye, brought on a gush of tears, and a paroxysm of violent pain. The cornea presented a solid leucomatous mass projecting from it, having almost a staphylomatous character; and on its most prominent point a small white scale was seen.

Being of opinion that this scale, together with the mass generally, was the cause of the pain, I determined to slice it off. On the following day, the patient having been chloroformed, the scale was first lifted off, and the mass then carefully pared off down to the level of the cornea. It was solid, and blood oozed from the cut surface. The lids were closed with strips of plaster, and wet rags were ordered to be applied. Twenty drops of liquor opii sedativus were given at bedtime. The patient passed an excellent night, and had no pain whatever.

The eye rapidly recovered from the operation, and the patient was discharged from the house on June 21st, and ordered to attend as an out-patient. The only further treatment required, was tonic medicine to improve the general health. It is satisfactory to find that he is now able to follow his occupation as a workman, and that the eye continues sound, with the exception of the opacity of the cornea. There has been absolutely no pain since the operation.

Under the microscope, the portion removed presented the characters of ordinary cicatrix tissue. The solid scale was

calcareous deposit, and had been attached to the apex of the growth.

CASE III. PUNCTURED WOUND OF THE EYE: HERNIA OF THE AQUEOUS MEMBRANE. For the history of the following case, up to the 1st of May, I am indebted to Mr. Lawrence, one of the resident medical officers of St. Mary's Hospital, who had charge of the case up to that time.

William Peach, aged 33, a metal fitter at the Great Western Railway, became an out-patient at St. Mary's Hospital April 21st, 1853. He had been struck on the right eye, a short time before application, by a nearly red-hot chip of iron, propelled with great force from a piece of metal which he was boring. On examination, there appeared a wound of the cornea towards the lower part of its inner half; but no foreign substance could be detected in it. The conjunctiva of the eye was slightly inflamed; there was considerable lachrymation, and some intolerance of light.

The eye was ordered to be covered, and the patient to take two grains of calomel with the fourth of a grain of opium, thrice daily; collyrium aluminis was ordered to be used occasionally.

April 22nd. The eye was more inflamed, and more painful. There was increased photophobia. Pulse 100, and full; tongue furred. Four leeches were applied to the temple. The pills and collyrium were continued.

April 23rd. The leeches bled freely, and the eye was much better. The conjunctiva was raised over the injured portion into a vesicle, so that the sight was disturbed.

April 27th. The eye was not so well, being more inflamed and painful. The mouth was slightly sore. Three leeches were ordered to be applied, and the treatment to be continued.

April 29th. The eye was less painful, and less inflamed; but the vesicle seemed to be increasing. He was ordered to see Mr. White Cooper.

April 30th. This patient came this day under my care; and the appearances were as represented in the sketch;

there was slight general congestion of the conjunctiva, most marked in the neighbourhood of the wound. The iris was not inflamed. A pear-shaped transparent vesicle projected from the cornea, quite over the margin of the lower lid. The pupil was contracted and distorted, the edge being apparently adherent to the wound. I could not satisfactorily make out whether the vesicle was the posterior elastic lamina projecting in a hernia-like pouch through the wound, or whether it was more anterior. There could be no doubt, however, that it was in connexion with the anterior chamber. From its large size, and its situation, interfering with the closure of the lids, I determined to puncture it, and, by the application of the nitrate of silver, to stimulate the union of the edges of the wound. On pricking the vesicle with a cataract needle, the fluid shot out, and it instantly subsided. The point whence the fluid escaped was lightly touched with nitrate of silver.

May 3rd. The vesicle had nearly regained its former size. It was again punctured and touched with the caustic.

May 6th. It was only about one-half its former size; but it was deemed advisable to puncture it once more, and to apply the nitrate of silver rather more freely than on the former occasions. The application was followed by a considerable amount of pain, which continued more or less for two days; there was, however, no active inflammation. From that time the wound healed, the surface of the cornea

merely presenting a linear cicatrix, indicating the situation of the injury. The pupil, being adherent at one point, remains oblong; but the sight of the eye is now nearly perfect.

REMARKS. The first case affords an illustration of a rather unusual result of injury to the eye. The appearances before the operation, namely, the livid palpebrae traversed by great tortuous veins, the hard, enlarged, and thoroughly disorganised globe, discharging an acrid sanious fluid from a foul and ragged fissure, and the intolerable pain, led to suspicion of malignant action; a suspicion favoured by the unhealthy, emaciated aspect of the lad. Cases are on record, in which diseases of the eye, of an innocent character, have been pronounced malignant, and treated accordingly. Professor Roser especially states that the mistake occurred to him, "to consider as fungus oculi a case of purulent choroiditis, which supervened on staphyloma, that had been cured several years previously, and which I first beheld when it was at the height of its development. I accordingly prescribed extirpation. In a case which occurred at a later period, which, still more illusively than the first, resembled carcinoma, a medullary fungus breaking forth through the eye, and in which nothing else was found than purulent choroiditis, with staphyloma of old standing, I was prevented from forming an erroneous diagnosis, solely by the circumstance that I had several times, at early periods, seen the child as a patient with staphyloma."

The effusion of blood deep in the eye sometimes gives rise to appearances which may be mistaken for malignant disease. At the present time, I have in attendance at St. Mary's a little child, into whose left eye a fork was thrust just at the junction of the cornea with the sclerotic, wounding the iris. It probably missed the lens, as there is no cataract; but, deep in the eye, there is visible a fawn coloured, metallic looking mass, just like the commencement of medullary disease. I was in doubt, for some time, whether the injury might not have excited some such morbid action; but I believe that is not the case, and that the appearance is merely fibrin, from which the red particles have been removed. I am the more led to this conclusion from two other cases which have fallen under my notice, where, in elderly people, a vessel had given way deep in the eye, producing sudden blindness, and causing first a red, then a brown, and lastly a yellow reflection from behind the lens.

In the case of James Cooper, the solid contents of the globe were probably the remains of blood which had been poured into the cavity; a condition at the first glance unsatisfactory, but really useful, as its firmness afforded an excellent cushion for an artificial eye. The benefit afforded by the operation was most marked; and the rapid subsequent improvement in the nutrition of the patient manifested how vast a relief had been afforded to the constitution.

Though the incision for the removal of the diseased parts passed through highly inflamed structures, it was attended with very little bleeding. Formidable hæmorrhage, however, occasionally takes place in similar operations; an instance of which occurred in my own practice, a few months ago. I removed a portion of a staphylomatous cornea from an enlarged and disorganised eye, for the purpose of sinking the globe. For thirty-six hours, with trifling intermissions, the wound continued to bleed, in spite of a variety of efforts made to stop it. In such cases, the erect posture, the local application of styptic fluids and pounded ice in bags, with such gentle pressure as a moderately tight compress will afford, are the best measures for controlling the flow of blood. As this is seldom from one point, but rather from many weakened and dilated vessels, neither ligatures nor caustics can be conveniently used. The globe often remains distended with blood; but much of this is subsequently absorbed.

When the wound made by the operation has nearly healed, it is not uncommon to find a few exuberant granulations lingering and retarding the cure. They should be touched

with sulphate of copper, and the eye bathed twice daily with a solution of alum or of tannic acid, which latter, in the proportion of four or six grains to the ounce, is very useful. The alum and tannic acid have been prescribed in combination; but a curdy precipitate of tannate of alumina is thrown down, and a large portion of tannin is rendered inert. By the treatment mentioned, the cicatrix soon acquires firmness, and the eye becomes free from mucous discharge.

The nature of the change by which such opacities, or such heaping up of abnormal tissue, as that described in case II, is produced, has been well explained by Mr. Bowman: "The nature of the nutritive process in the lamellated tissue is such, that this tissue recovers itself in a great measure, by timely treatment, from almost any amount of inflammation, and consequent effusion, which falls short of actual destruction of its elements; but when these elements are at all displaced or consumed under the morbid process, then permanent opacity is very likely, and, indeed, almost certain, to follow; for so artificial is the mechanical arrangement of the elementary lamellæ, on which the transparency of the cornea depends, that when their substance is once removed, its place cannot be supplied with a tissue of an equally elaborate organisation. The new material, though its bulk and strength may be equivalent to those of the old, is fibrous instead of being lamellated, and opaque instead of being translucent. It contains a considerable quantity of yellow tissue, intimately mixed with the white, and both most irregularly interwoven and ill-developed—ready to become the nidus of small granules of earthy or fatty matter, such as readily settle in parts of deteriorated structure."

The presence of such earthy or ossific deposit in the eye is far from uncommon; osseous cataract being perhaps the most frequent example. Of this, a very excellent specimen was exhibited at the Pathological Society by Mr. Canton, in May 1851; the capsule of the lens was completely converted into calcareous material, and osseous patches had been formed in several places between the retina and choroid. It was taken from a woman aged 73, who, thirty years before her death, had received a blow on the eye, followed by wasting of that organ.

It does not necessarily follow, that ossific deposits in the eye should be attended with neuralgic pain; but they are so in a large number of cases. In the first volume of the *London Journal of Medicine*, four cases were related by me, which illustrate this point. The case above described affords another example; and one very similar is mentioned by Mr. Bowman. A girl, aged 14, was brought to that gentleman, suffering from severe inflammation of the eye, which had been partially sunk several years before, and in which no perception of light remained. The irritation was very great, especially on every movement of the lid: on examination, a hard, angular piece of bone was observed, imbedded in the front of a dense opacity of the cornea, and projecting beyond it, quite bare. The fragment, which was of the size of a large pin's head, was easily removed with a pair of forceps, and the patient speedily got well.

I am an advocate for the use of the knife, in preference to escharotics, for removing leucomatous growths or tumours from the eye; it is more sure, more speedy, more manageable, and less painful. In a few cases which have fallen under my notice, where inflammation has followed excision, it could generally be traced to long continued and abortive attempts to pare off the growth, accompanied with violent pressure on the eye to steady it. If chloroform be used, the operation can be performed at once with neatness and a light hand, and the relief is immediate.

19, Berkeley Square, July 1853.

CASE OF RUPTURE OF AN ANEURISM OF THE TRANSVERSE PORTION OF THE ARCH OF THE AORTA INTO THE TRUNK OF THE PULMONARY ARTERY.

By W. BIRD HERAPATH, M.D.

On a Sunday evening, at half past nine, P.M., I was summoned to attend Mr. Charles M—— R——, aged 53, who was then residing near me. I found him in bed; he was complaining of pain in the epigastrium, and of disposition to nausea, which had been increased to vomiting by the ingestion of warm water. He had an uneasy sensation in the bowels, with slight relaxation also. The substances ejected from the stomach were highly charged with acid. He also suffered from thirst; the tongue was, however, clean; the pulse was quicker than it ought to be, 100, soft and regular. The skin of the extremities, where exposed, was cold and moist, but under the bedclothes, warmer. He had no headache. The respiration was somewhat quicker than usual; he also had a slight cough, with frothy mucous expectoration; he compared the pain in the epigastrium to a constant burning sensation. He had often suffered from it before; and had hitherto always obtained relief from a draught of cold water. This had failed, as well as the emetic treatment on the present occasion.

The history of the case was the following, as given me by the wife. He was a brewer and distiller, and had held a situation in a neighbouring brewery during the last six months. He was rather fond of Scotch whiskey, and generally had several glasses of "toddy" during the day at intervals; but he was never intoxicated. The day previously, he attended to his duties as usual, and came home in the evening in his ordinary state of health. He had supped on beef, which was not fresh or good. The child had also eaten of the same dish, and not liking it, declined taking any more. Mrs. R. could not eat it, as it tasted strange and "fusty". He had tried to go to church on the Sunday, but came home again faint, and had taken no food. Taking all these circumstances into consideration, I thought that he laboured under gastralgia, from acidity; that the faintness and depression were produced by the emetic and exertion, together with abstinence from food and stimuli during the day.

I prescribed a pill containing four grains of calomel and one grain of opium, to be taken directly, and an antacid saline aperient, with some compound spirit of ammonia, every two hours; a mustard cataplasm to the epigastrium, and bottles of warm water to the feet; a little arrowroot and brandy as diet. At this time he only sent for me in consequence of the advice of a friend: the patient himself did not think it necessary to have a medical man.

About a quarter before eleven the same evening, I was again summoned to this patient, who was stated to be much worse. Thinking it to be over anxiety and timidity, I at first advised perseverance with the remedies; but a second messenger, following on the heels of the first, said that he was certainly dying, and begged my instant attention. In crossing the road, I met a third on the way to me. This had prepared me for a great and sudden change; but I certainly was not a little surprised to find my patient moribund. He was pulseless; cold; clammy; the face was pallid; the eyes glazed and insensible; no reflex excitatory phenomena of eyelids; and the jaw fallen. He made two or three convulsive gasps, and all was over. I attempted to restore animation by placing the head low, and applying burnt and smouldering rag under the nostrils, whilst I at the same time induced and kept up artificial respiration, by alternately compressing the thorax, and relaxing the pressure on the ribs. The heart was auscultated, but it had ceased to beat: and all attempts to restore animation were unavailing.

Upon more calmly questioning the spectators of the last moments of this sudden calamity, the following facts were elicited. He had complained of being worse and in more agonising pain, and of having more difficulty in breathing.

All at once he was seized with a "few spasms, not convulsions"; he became blue in his face; made some rattling noises in the throat; a cold clammy perspiration stood on his face in large drops; he groaned repeatedly as if in great pain; this groaning gradually became a dull moaning sound; then the countenance and skin assumed a dull slate colour; the eyes rolled about spasmodically; the patient appeared to fall into a comatose, stupid, or unconscious condition and rapidly assumed that appearance in which I found him. In the meantime he had been raised from the recumbent to the sitting posture, and the features were bloodless and pallid when I came in.

The whole appearances to me were those of a combination of syncope with asphyxia. As, however, considerable doubt remained as to the cause of these symptoms, and even some suspicion subsequently arose as to whether he had not committed suicide in consequence of some existing mental disquietude, it became my duty to acquaint the coroner with the whole circumstances of the case and await his decision, before I proceeded to request a *post mortem* examination.

In my letter to him, I hazarded the conjecture that one of four causes produced death: suicide or other poisonous agency; rupture of the stomach or duodenum from perforating ulcer; laceration of an aneurismal sac and internal hæmorrhage; or an epileptic attack merging into apoplexy. In the absence of further evidence, however, a decided opinion could not be arrived at.

EXAMINATION OF THE BODY, BY ORDER OF THE CORONER; EIGHTEEN HOURS AFTER DECEASE. The surface of the abdomen was thickly covered with fat, and the whole body was plump and well nourished. There were no appearances of violence; no ascites or anasarca; on opening the peritoneal and thoracic cavities, there were no traces of peritonitis, or any evidence of hernia, intussusception, or other intestinal displacement. There was no hæmorrhage; no rupture or perforation of the stomach or viscera. The pleural and pericardial cavities were free from fluid.

The coats of the stomach and smaller intestines were uniformly engorged with blood; all the branches of the portal system were in a highly congested state.

The lungs were equally gorged with blood. The vesicular structure, however, was everywhere crepitating; and there was no appearance of blood having been extravasated into the pulmonary structure, or of recent pneumonia.

The stomach and œsophagus were carefully dissected out, as it at first appeared necessary to undertake a chemical examination of their contents. There were no traces of any corrosive irritant, however, upon the œsophageal mucous membrane. The stomach contained about a wineglassful of dark coloured fluid, somewhat bloody. The gastric mucous membrane was everywhere gorged with blood; many ecchymosed patches of small extent being evident. The whole surface was dotted over with these, and some long narrow streaks of ecchymoses marked the rugæ, and were very apparent; and three small ulcerations existed at the lesser curvature. These appearances were so similar to those produced by an irritant corrosive poison, that considerable care was taken of the whole viscera and their contents. The intestinal mucous membrane presented the same pathological appearances, more especially that of the duodenum and the jejunum. The large intestine was empty, the coats were covered only by a whitish creamy mucus; they were destitute of feces and fœtor. There was a small portion of feces in the cæcum.

The heart was now examined; and then arose a change in the whole aspect of the case. The pericardium was empty, and not adherent; the heart was flabby and large; its muscular coat was pale. The aorta was dilated very considerably, and was strongly adherent to the pulmonary artery. The lining membrane was diseased, being rugous, roughened, and atheromatous throughout. At one portion of this vessel a lacerated opening was found. This was situated on the anterior and inferior wall, at the junction of the transverse with the descending portion of the arch of the aorta; it was three-quarters of an inch in length and about one-third of an inch in width. The edges were

everted. A probe used very gently passed through it into the cavity of the pulmonary artery; around the borders of the opening in the aorta were red patches of fibrin, in flakes, adherent to the serous coat; some few were between this and the middle coat. No distinct aneurismal pouch was apparent; but a thinning and semiprotusion forwards of the aorta was somewhat perceptible in this position. Upon slitting up the pulmonary artery—carefully avoiding the probe—the serous membrane was found lacerated to the extent of an inch in width, horizontally or transversely just above the free border of the anterior semilunar valve. Upon lifting this free and lacerated edge of the loosened serous membrane, a cavity was found underneath it, capable of holding a pigeon's egg. This cavity was not an ordinary aneurismal sac, but was merely produced by the dissection of the serous from the fibrous coat of the vessel. The superior border of the cavity was convex upwards, and extended to within half an inch of the pulmonary insertion of the ductus arteriosus, which was distinct from and not implicated in the disease. No clots were found in this cavity, nor any fibrinous layers; but, at the superior border, a thin waving line of clot marked the boundary of the dissecting process. The whole loosened serous membrane now appeared more like a loose valvular fold superposed on the aperture of communication between the two large vessels. Previously, however, to the laceration of the serous membrane of the pulmonary artery, it must have formed the wall of an aneurismal sac protruding into the cavity of this vessel, and greatly interfering with its duties. The calibre of the vessel must have been more than half obstructed; and the whole of the right side of the heart and veins, both systemic and portal, gorged with blood, even to the cutaneous and mucous capillaries; hence the decided cyanosis preceding dissolution. Soon after this followed the rupture of the serous layer; and then took place the engorgement of the pulmonary capillary system, the spasm, with attendant syncopal asphyxia, and pallor of countenance, so marked upon my entrance; the systemic capillaries being relieved at the expense of the capillaries of the pulmonary circulation.

The valvular apparatus of the aorta, and pulmonary artery, and right ventricle, were perfectly healthy and efficient. The mitral nerve was thickened and indurated; some patches of calcareous matter were deposited at its base, and in the anterior plate: it was perfectly capable of performing its functions. The sinuses of Valsalva were large and aneurismal. The left ventricle was hypertrophied to some extent; the right ventricle was dilated slightly, but this arose just before death, from distention, in consequence of the accident interfering with the course of the systemic venous circulating current. The pulmonary artery was not dilated; its external circumference being precisely the same as that of a healthy adult, namely, three inches. The calibre of the aorta was dilated.

The pleurae were extensively adherent on the right side, and slightly on the left. The lungs contained some minute hardened bodies in the intralobular spaces, and disseminated between the pleura and vesicular structures. These were numerous, and not unlike minute tubercles of the miliary variety. The trachea and bronchial tubes every where contained frothy saliva. The vascular system of the lungs was universally in a state of distension, but the blood had not a florid hue. It is probable that the length of time elapsing before death was sufficient to blend the whole circulating current, and render it homogeneous: and secondly, the period intervening since the fatal result would be sufficient to remove any arterial tint. The blood was perfectly fluid, and such as we invariably find it in cases of asphyxia. The quantity of circulating medium was above the average, and was certainly at variance with the appearances of syncopal prostration, as observed before death. The coronary arteries had commencing fibrinous deposits within their coats, disseminated at various distances; but no calcareous matter was yet apparent. The brain was perfectly healthy; and the vessels did not present any unusual turgescence, or any morbid appearance.

In order to obtain more exact data of the extent to which the aortic dilatations had proceeded, the following measurements were taken, and compared with those of a normal aorta:—

	Case.	Normal.
Internal circumference of the aorta at the superior border of the aortic valves	2.85	3.00
Internal circumference at the level of the lacerated opening, situated about 1.4 inch above the superior border of aortic valves	3.50	3.00
Internal circumference at the origin of the brachio-cephalic artery	4.30	2.80
Internal circumference after the origin of the left subclavian, and at the remains of ductus arteriosus	3.15	2.40
Length of arch of aorta, from the attachment of the anterior and left semilunar valves to inferior edge of the brachio-cephalic origin	3.00	3.00
Internal circumference of pulmonary artery	3.00	3.00

The following CONCLUSIONS may be drawn from an examination of this case:—

I. That aortitis had existed for some time previously to death.

II. That dilatation or true aneurism of the ascending and transverse portions of the arch of the aorta also existed during some considerable period antecedent to the fatal accident.

III. That this dilatation was not sufficiently extensive to produce the *general* symptoms of aneurism of the aorta, the pressure on surrounding parts not having been sufficient.

IV. That it is probable that the stethoscope would have discovered the disease by the physical signs, viz., "a rough, harsh sound, loudest above the clavicles, and beneath the first bone of the sternum"; whilst there would have been little or none over the region of the semilunar valves, or at the apex.

V. That a purring tremor might have been discovered in the same situation, more especially at the root of the neck.

VI. That the rupture of this dilated aorta took place immediately preceding death.

1. From the absence of the peculiar pulse at the first visit, at 9½ P.M.

2. From the total absence of dropsy, and any appearance of cyanosis, or other marked derangement of the circulating apparatus at this period.

3. From the sudden and well marked supervention of these important symptoms.

4. From the ragged and lacerated appearance of the opening, and the absence of coagula and blood stains in the cavity of the false aneurism, and from the non-dilatation of the pulmonary artery, it is evidently one of sudden formation.

I consider this case as one of importance in a physiological as well as in a pathological point of view; and that it proves the following general propositions:—

I. That, in rupture of the aorta into the trunk of the pulmonary artery, death may take place suddenly from syncope asphyxia; the embarrassment of the circulation and respiration being sufficient to occasion death.

II. That, under these circumstances, no blood escapes from the hydraulic apparatus; the vascular system being as full as ever.

III. That dyspnoea would exist as a prominent symptom, arising from the excessive and irremediable engorgement of the pulmonary capillaries.

IV. That dropsy does not occur under these circumstances, the death being too instantaneous to admit of its occurrence; but, should life be prolonged, the congestion of the systemic and portal capillaries would occasion it.

V. That the size of the orifice of communication would probably determine the occurrence of sudden or protracted death; a small opening, gradually enlarging, being likely

to permit of the patient rallying from the first shock, and gradually accommodating himself to the accident.

VI. That, although a communication was established between the aorta and pulmonary artery, yet there existed a great difference between the circulation and that of the fœtus or the new born infant before respiration.

1. The valvular nature of the opening demonstrates that the current must have been from the aorta to the pulmonary artery. In the new born infant and fœtus, it is from the pulmonary artery to the aorta.

2. The cause of the cyanosis in these cases cannot be the same. It probably arises from the fact that the current of venous blood, propelled by the weak right ventricle, is hindered in its course, in consequence of the stronger action of the left ventricle producing a more powerful current of arterial blood, and from the aortic elasticity being more constant in its action, by which means the semilunar valves of the pulmonary artery are *kept in a state of tension*; and the course of the venous current being thus retarded, a state of general congestion and cyanosis results.

REMARKS. The importance of this case of rupture of the aneurismal aorta into the pulmonary artery will appear from the scanty literature of the subject.

Rokitansky and Andral do not give any case of the kind. The Museum of the College of Surgeons of England contains, in its pathological department, two specimens of aneurism of the *ascending* (intrapericardial) portion of the arch of the aorta opening into the pulmonary artery (Nos. 1650 and 1651). In the latter case, it is mentioned that the patient died of jaundice and dropsy; the aneurismal disease not being distinctly indicated during life. Dr. Hope never saw a case; but he gives the details of one which Dr. David Monro of Edinburgh observed, and kindly communicated to him (p. 469). Dr. Copland, in his *Dictionary of Practical Medicine*, vol. i, p. 74, states, that three cases are on record; one related by Dr. Wells, in the *Transactions of Society for the Improvement of Medical and Chirurgical Knowledge*, vol. iii, p. 85; a second by M. Sue (*Journal de Médecine Continentale*, tome xxiv, p. 124); and a third by MM. Payen and Zeink (*Bulletin de Fac. de Méd.*, No. 3, 1819.)

Mr. Thurnam's paper on Aneurisms of the Heart, in the *Medico-Chirurgical Transactions*, vol. xxi, does not contain an instance, although he gives the analysis of seventy-four cases. The *Lancet* contains a case, in which an aneurismal tumour of the aorta threatened to burst into the pulmonary artery. This is the only one contained in it at all similar (vol. ii, 1850, p. 605).

As Dr. Monro's case differs very materially from the one which has fallen under my notice, I will transcribe it in full. It is contained in Dr. Hope's work, 3rd edition, p. 469.

James Evans, aged 24, a porter, admitted into the Edinburgh Infirmary, Oct. 30th, 1833. Accustomed from his profession to lift heavy weights. Had a severe attack of acute rheumatism about ten years ago. About ten months ago, had an attack of pneumonia, which yielded to copious depletion. To this he ascribed his symptoms, viz., palpitation, dyspnoea, followed, three months before admission, by swelling of the abdomen and lower extremities, which has gradually increased.

On admission, the following were the symptoms: great dyspnoea, amounting to orthopnoea; abdomen much distended, and fluctuation; lower extremities swollen and tense; countenance tumid, and somewhat *livid*; great general uneasiness; action of the heart tumultuous, diffused over a large space, not *strong*; cough, with expectoration; pulse large, harsh, and thrilling, 112.

Physical Signs. Much dullness on percussion in the præcordial region: first sound accompanied by a loud soufflet, audible over the whole fore part of chest, and on the back on both sides of spine, but most distinct at middle of the sternum: second sound short, and much obscured by the first; hence it appears that a *continuous* murmur extended from the first over the second sound. The treatment employed, viz., digitalis, calomel, and squills, had the effect of reducing the pulse, and increasing the quantity of

urine, but produced no impression on the symptoms. His general uneasiness continued, though temporarily relieved by a small bleeding. The pulse became intermittent some days before his death a fortnight after admission.

Autopsy. Much anasarca. The chest contained several pounds of serum in both pleuræ. The heart, enveloped in the pericardium, occupied a great part of the left side, displacing the corresponding lung. It was found to be more than twice the natural size, pale, flabby, and blunt towards the apex. All the cavities were much dilated, together with the corresponding orifices. The walls of both ventricles retained their natural thickness. All the valves were healthy, excepting the semilunar at the mouth of the aorta, which were thickened. The aorta itself, from its origin to the arch, was dilated into a large irregular sac, which adhered firmly to the pulmonary artery, and communicated with it by two openings, situated an inch and a half from the valves; the largest capable of receiving the point of the little finger; the smaller, of transmitting a crow-quill. The edges of both were regular, round, and cartilaginous. Nearer the arch, a third smaller opening was discovered, with thin rugged edges. The internal membrane of the dilated portion of the aorta was reddened and rugous, from numerous cartilaginous patches, which had advanced in some parts to ossification.

In comparing this case with one of rupture into the right ventricle, Dr. Hope makes the following remarks:—

1. A lift was the immediate cause of the symptoms, although disease of the aorta had preceded. 2. Pulse pre-eminently jerking; for such was evidently the large, harsh, and thrilling pulse of Dr. Monro's case. 3. A loud superficial murmur, with both sounds incessant in one case, and apparently so in the other, judging from Dr. Monro's description. 4. A livid venous tint of complexion. 5. A great, rapid, and universal dropsy.

And he gives the following, as signs of aneurism of the aorta opening into the pulmonary artery:—

Physical Signs. 1. A very loud, superficial, sawing murmur, prolonged continuously over the first and second sounds, probably weakened during the interval of repose, and loudest along the tract of the pulmonary artery. 2. A purring tremor in the pulmonary artery, in the interspace between the second and third ribs. 3. The second sound weakened at the clavicles.

General Signs. 1. The jerking pulse. 2. Great, rapid, and universal dropsy. 3. Livid venous tint. 4. The circumstance of the symptoms having followed an effort would afford corroborative evidence.

I am indebted to Mr. J. S. Soden, of Bath, for this report of Dr. Wells's case.

CASE. Mr. A. B., a merchant, of a fair complexion, thin make, and temperate habits of life, in 1789, being then thirty-five years old, became affected with symptoms which were thought to denote the approach of pulmonary consumption. These, however, after some time, entirely disappeared. In 1798, he was attacked with a slight hemiplegia, from which his recovery was soon so nearly complete, that the only inconvenience left by it was an inconsiderable sense of coldness in the foot of the side which had been affected with palsy. In March 1804, he complained to me of being frequently troubled with a noise in his ears, flatulence in his bowels, and pains in his hands and feet, sometimes attended with slight swellings in the same parts. From one or more of these symptoms he was never, I believe, long entirely free during the remainder of his life. He never spoke to me, however, concerning any unusual feelings in the chest; and I have not learned upon inquiry that he ever mentioned his having such feelings to any of his friends or relations, after his recovery in 1789, though his attention was always much directed to the state of his health, and he was not indisposed to make it a subject of conversation.

On the 11th of August, 1807, he fatigued himself considerably with walking. Upon his return from London, on that day, to his house in the country, he ate rather a full dinner, and, having fallen asleep afterwards, he felt so much refreshed in the evening, as to play with his children in the

garden. While thus amusing himself, he was suddenly seized, between eight and nine o'clock, with a sense of great oppression in his chest. He soon after became sick at the stomach, and vomited; in the matter thrown up, some streaks of blood were observed. He now went to bed; but, though the weather was warm, and he was covered with bedclothes, his skin felt cold to those who were attending upon him. Mr. Bliss, a medical practitioner at Hampstead, saw him soon after midnight. He then laboured under a constant desire to cough, and was continually expectorating mucus tinged with blood. His body was moistened with a cold sweat; and his pulse was extremely feeble, sometimes it was scarcely perceptible. Mr. Bliss having declared him to be in great danger, a messenger was sent to desire me to see him; but, as I happened to be from home, the messenger applied to Dr. Baillie, who in consequence visited him about five o'clock in the morning. His pulse was then very feeble and irregular; his breathing difficult; his skin pale, cold, and covered with a clammy sweat. Frequently he tossed and writhed his body, as if he was suffering great pain or uneasiness. The faculties of his mind, however, seemed unimpaired. Dr. Baillie concluded, from what he observed himself, and from what he was told by Mr. Bliss and the patient's attendants, either that a large quantity of serous fluid had been suddenly effused into the cellular texture surrounding the air-cells of the lungs, or that some considerable blood vessel had been ruptured in the chest. Mr. B., about a quarter of an hour after Dr. Baillie had seen him, became suddenly worse, and in a few minutes expired. Almost immediately before his death, he complained much of heat in his chest, and threw off the bedclothes.

Two days after death, the body was opened by Mr. Bliss and his partner, Mr. Haynes, when the following appearances were observed.

The blood-vessels of the lungs were very much distended, and there was also a considerable quantity of blood in the air cells. The right lung adhered slightly to the ribs and pericardium; but this seemed to have been the consequence of some disease which had existed long before death. Each cavity of the chest contained about ten ounces of a fluid highly tinged with blood. The pericardium contained about two ounces of a fluid similarly tinged. The ascending aorta was distended to about the size of a large orange. The tumour adhered to the pulmonary artery, just before its division into the right and left branches. Within the circumference of this adhesion, there was a narrow hole, by means of which a communication was formed between the two arteries. The cavities of the heart and the great blood vessels were very much distended with blood. The diseased portions of the aorta and pulmonary artery were afterwards seen by Dr. Baillie and myself. Dr. Wells says: "The occurrence of such a disease as I have described might be readily imagined; but I have found no instance of it in the books which I have read; and no previous example of it, I believe, had been seen by any of the surgeons or anatomists of London." Also: "It will be admitted, I suppose, that the communication between the aorta and pulmonary artery took place on the evening before the patient's death, when he first felt an oppression in his chest. In consequence of the superior strength of the left side of the heart, a part of the blood, which was thrown by it into the aorta, must have been forced into the pulmonary artery; from which circumstance an explanation may readily be derived of all the symptoms the patient laboured under, except the sickness and vomiting. These would probably have occurred if any other great disease had attacked him shortly after a full meal, without proving immediately fatal."

I have also been kindly furnished with the following report of M. Sue's case, by Dr. Peacock. It is evidently the same as that of MM. Payen and Zeink. It is entitled, "*Observation d'une Aneurisme de l'Aorta s'ouvrant dans l'Artere pulmonaire, et l'obstruant.*" Par M. Sue: recueillie et présentée à la Société par MM. Payen et Zeink."

CASE. Lefrère, a soldier of the Imperial Guard, aged thirty-eight years, was admitted into the military hospital in July 1808. He had been ill eight months, suffering

from palpitation and sense of suffocation, caused by walking quickly, or by ascending stairs. He was compelled to sit constantly upright in bed; face swollen, lips livid, respiration difficult, pulse almost imperceptible; he became anasarcaous, and gradually got worse: four days before his death, he became jaundiced, and died exhausted in February 1809.

Autopsy. The pericardium contained some fluid. The heart was of its natural size, with traces of inflammation on its surface. The pulmonary artery was greatly dilated, and, on being opened, was found to contain a tumour of the size and shape of a small egg, and *this being cut open*, the finger passed into the aorta. The aorta was dilated at its curvature, and the aneurism proved to have been formed in the aorta, and to have become adherent to the pulmonary artery; and had destroyed its parietes, and closed the orifice. The liver was fatty, but the viscera otherwise healthy.

The case, adds Dr. Peacock, is not very clearly described; and it does not appear that the aneurism had formed any opening into the pulmonary artery.

It follows, from carefully reconsidering these reports, that there are only *three* cases of rupture of an aneurism of the aorta into the pulmonary artery on record: Dr. Wells's case, Dr. Monro's case, and my own. The one related by M. Sue, and quoted by MM. Payen and Zeink, was merely that of an aneurismal tumour pressing on the pulmonary artery, and partially obstructing it, eventually causing dilatation of the vessel. It is so far similar to the one detailed in the *Lancet*.

Dr. Wells's case and my own agree in many respects, more especially in the suddenness of the fatal attack, and the insidious nature of the progress of the disease, merely being marked by slight palpitation, dyspnoea, cough, followed by vomiting, burning heat in the chest or epigastrium, and pain; then by sudden dyspnoea of a greatly aggravated character, prostration, and collapse: cyanosis in my case, pallor in his; asphyxia predominating in mine, syncope in his; coma then following in mine, but the sense remaining unimpaired in Dr. Wells's; death taking place about nine hours after the fatal calamity in his case, but occurring almost instantaneously in mine.

Dr. Monro's case is remarkable for, there having been found three perforations, the symptoms having lasted over as many months as in the other cases hours and minutes: the extent to which the circulatory system was embarrassed was, therefore, considerably greater; but, in consequence of the gradual manner in which the chain of events came on, the body became accustomed to the change, and probably some pathological balancing power accomplished. Do the anasarca and ascites thus act? It is certainly very extraordinary that such a serious derangement of the apparatus of circulation should have existed, without death having come on at an earlier period. It is probable that Dr. Monro's case permitted a free circulation of mixed arterial and venous blood, and that the force of the left ventricle was not therefore thrown on the pulmonary capillaries; for the rounded, cartilaginous openings, in Dr. Monro's case, are decidedly an evidence of the communications having been made in a more gradually progressive manner, and from a different pathological cause. Were they the result of ulceration in his case? Mine was decidedly a lacerated opening, and so was that in Dr. Wells's case. The number and size of the communications would allow a perfectly equalized circulation between the two arteries; and probably the livid cyanosis in Dr. Monro's case arose from very nearly the same physiological cause as exists in the fetus through the ductus arteriosus.

In Dr. Wells's case, the size of the opening and its character are not stated; it is merely said to be a *narrow one*; and probably, from the detail of the case, occurred nine hours before death, and commenced in sudden laceration. Dr. Wells does not state whether any hypertrophy of the left ventricle existed; but *all* the cavities were distended with blood: therefore, I should imagine that it was dilated, and weakened in its power.

Bristol, July 1853.

PERISCOPIC REVIEW.

MICROSCOPICAL DISCOVERY.

THE STRUCTURE OF TISSUES.

Virchow's Archiv, v, 270, contains an interesting paper by Dr. F. Hoppe, on certain chemical researches into the anatomical structure of various tissues. These are based upon the fact that animal structures which can be exposed to the action of water boiling under a pressure of three atmospheres for several hours without being dissolved, are not of gelatinous character. In this way a mechanical analysis of the tissue can be made, the gelatinous part is dissolved away, and the cells are demonstrated, by their resistance to the action of the boiling water, to be perfectly distinct from the intercellular matter, to have non-gelatinous walls of their own, and thus to be in all cases more than mere cavities in the surrounding tissue.

Small portions of cartilage, enclosed in glass bulbs, were boiled under high pressure in a Papin's digester. The intercellular substance was dissolved, and the cells could be detected by the microscope, floating free and uninjured in the fluid. Elastic fibro-cartilage, treated in the same way, gave a like result: all was dissolved except the fibres and the cells, which were found free in the solution of chondrin; disproving Mulder's dictum, that "the cells of fibro-cartilage yield chondrin on being boiled."

Bone was next examined; the earthy matter having been removed by a weak acid, small fragments of the animal matter were boiled, as above described. All was dissolved except the cells, which were found, as in the other cases, in the fluid, with portions of the canaliculi still connected with them. Our author concludes that the corpuscles and canaliculi of bone are no mere hollows or canals in the tissues, but have independent walls of their own, containing no gelatinous matter, and distinguished from the surrounding bone substance, exactly as the cells of cartilage are from the seemingly structureless matter in which they are imbedded. Our readers cannot fail to be interested in this experiment, taken in connexion with the facts respecting the structure of bone which we recorded in a former number. Dentine, submitted to the same ordeal, underwent changes precisely analogous to those observed in bone; and Hoppe concludes, respecting tooth substance also, that the tubes and fibrillae which it contains, possess walls of their own,—of a smooth, thin, membrane, containing no chondrin. Other tissues consist of cells alone, without intervening matter; and, in general, the tissues of the vertebrata may be arranged in two classes: 1. Those which consist of cells and intercellular matter, as areolar tissue, cartilage, fibrocartilage, bone, and tooth; 2. Those which consist of cells alone, as epithelium, muscle, nervous and elastic tissues. This division holds chemically, anatomically, and also physiologically; since the first class compose the supports of organs, the latter the organs themselves.

NERVES OF THE HEART.

A. CLOETTA (*loc. cit.* v. 274) gives the result of his microscopical examination of the nerves of a hypertrophied heart. He has, indeed, done little more than confirm the observations of Dr. R. Lee, on the increased development which these nerves undergo in such cases; a development precisely analogous to that which the same author so successfully demonstrated to take place in the uterus, hypertrophied from natural pregnancy. The matter is well worthy of our notice, chiefly for the practical purpose of observing how closely mere nervous (so-called "functional") disturbance of the heart's action may be connected with the subsequent induction of organic disease.

Cloetta found that the nervous filaments, where they happened to cross arterial twigs, presented small swellings; but he cautiously adds, that the examination he made did not enable him positively to say what proportion of the said enlargement depended upon real increase in the nervous tubules, and what upon hypertrophy of the fibrous neurilemma. Our readers, who are acquainted with the structure of the spleen, will readily recall to mind the error which might be committed in respect to the large nerves of that organ in certain animals, by supposing them to owe their unusual size to nervous matter, while they are in truth indebted for it to the dense neurilemma alone.

THE RELATION OF THE APPEARANCES IN THE URINE TO DISEASE OF THE KIDNEY.

A paper upon this subject by C. E. L. MAYER (*loc. cit.* v, 199) is well worthy of perusal. He attempts, by careful examination

of the urine during life, and of the kidney after death, to resolve the following questions :

1. In cases of mere catarrhal or fibrinous inflammation of the kidney, does the urine present appearances similar to those which occur in the more serious structural degeneration commonly called Bright's disease?

2. Can the first named slighter inflammatory affections of the kidneys be detected during life, in the course of other diseases, by an examination of the urine, with the same frequency as they are found to have existed by inspection after death?

3. If the first question is to be answered in the affirmative, is there any possibility of distinguishing, in examination of the urine, between the changes induced upon it by the slighter, and by the more serious cases above mentioned?

The importance of these questions must at once be understood: and, in fact, we fancy that most practical men have already revolved them in their minds; for how often does it happen, in cases of scarlatinous dropsy, for example, that we observe the urine turbid, bloody, or albuminous, or pale, moss-water like, and also albuminous; in fact, presenting derangements much more remarkable than those accompanying many cases of incurable Bright's disease, and yet the patient, in the course of a week or two, restored to health, with sound kidneys, and urine perfectly natural?

In reply to the first question, our author concludes that, even in the slightest forms of inflammatory affection of the kidney, occurring in the course of other diseases, the urine is found to contain albumen and plastic coagula from the tubuli uriniferi, the latter of course to be detected in the fluid by the aid of the microscope; in fact, that there exists no case of such renal inflammation, without the consequent appearance of these coagula in the urine.

With regard to the information which may be gathered from the appearance of these casts of the urinary tubules, as to the actual condition of the kidneys, he finds that the greater their consistence and refractive power, and the less their solubility in muriatic acid, the more intense is the inflammatory action, while the greater their number, the more widely is it spread over the organ; but that there is no constant relation between the quantity of albumen in the urine, as displayed by the usual tests, and the number of these casts.

The simpler inflammatory affections of the kidney may be of very short duration, the organ being very rapidly restored to health, or, on the other hand, they may last very long, and yet without inducing any deep seated degeneration; and the answer to the third question above stated thus becomes most important. After a full examination of the point, our author comes to the conclusion that while, by the examination of the urine, we may generally distinguish between acute and chronic renal disease—the former giving rise more frequently to the appearance of blood and of small albuminous masses in the urine—we have no certain mode of distinguishing between chronic cases of renal catarrh or simple inflammation, and chronic cases of deep seated Bright's disease. We are thus left to gather from the general symptoms the information which the simple examination of the urine will not yield us, and to study the condition of the patient with respect to anæmia, dropsy, vital power, duration of the disease, etc., before coming to a conclusion.

Here we are reminded of the great principle which we endeavoured to inculcate in our introductory article on microscopical discovery and its use in practical medicine—that all special means of investigation, whether by the stethoscope, the test-tube, or the lens, are always by the good and safe physician held in due subordination to the great radical principles of our science, and thus only can they be considered as more than a delusive *ignis fatuus* by the bedside.

THE RELATION OF DISEASE OF THE LUNGS TO PHLEBITIS.

Four cases have been published by W. GRIESINGER (*loc. cit.* v, 391), with a view to determine the precise relation between these diseases. It is of course well known to our readers that lobular pneumonia is a frequent consequent upon purulent infection of the blood; and Cruveilhier and others, in figuring or describing such occurrences, refer them to what we have long believed the true cause, the entanglement in the capillaries of these very vascular organs, of the pus or colourless corpuscles, and consequent obstruction to the circulation in the affected part. Our author's researches go so far to confirm this conclusion: he found, in two cases in which the lungs were unaffected, that the quantity of colourless corpuscles was the same in the blood of the right and that of the left side of the heart; while

in two cases, accompanied by considerable pulmonary disease, the pus-corpuscles were found in multitudes in the blood of the right side of the heart and pulmonary arteries, and very sparingly in the arterial blood. The conclusion he draws is, that they had been arrested in the lungs, in consequence of their comparatively large size, and the feeble circulation of the exhausted patient. The fact, at all events, is worthy of note.

He noticed, also, in a case of "leukæmia" (leucocythæmia of Bennett), that the white corpuscles were much more numerous in the splenic artery, than in the corresponding vein; a curious circumstance, tending, if confirmed, to show that the enlargement of the spleen, so usually connected with this very curious and interesting disease, is the *consequence*, and not the cause, of the abundance of white corpuscles in the blood. For our own parts, we are rather inclined to think that this may turn out to be the correct theory of the disease; for we cannot consider it as proved, that the spleen is the organ either for the destruction or creation of blood corpuscles.

ASSOCIATION INTELLIGENCE.

SHROPSHIRE BRANCH: ANNUAL MEETING.

The Annual Meeting was held on Tuesday, July 26th, at the George Hotel, Shrewsbury, under the presidency of ROBERT BROUGHTON, Esq., of Ruyton. The following members were present:—

Samuel G. Bakewell, M.D. (Church Stretton); Jas. Bratton, Esq. (Shrewsbury); R. Broughton, Esq. (Ruyton), President; Edward Burd, M.B. (Shrewsbury); Peploe Cartwright, Esq. (Oswestry); T. J. Drury, M.D. (Shrewsbury); W. Eddowes, Esq. (Pontesbury); W. Fuller, M.D. (Oswestry); S. B. Gwynn, Esq. (Wem); Joseph Hickman, Esq. (Brockton); J. R. Humphreys, Esq. (Shrewsbury); J. Rider, Esq. (Wellington); R. Thursfield, Esq. (Broseley); F. Webb, Esq. (Wellington); M. Webb, Esq. (Wellington); Richard Wilding, Esq. (Church Stretton); Samuel Wood, Esq. (Shrewsbury).

Mr. George Hastings, the Secretary to the Association Reform Committee, also attended the Meeting.

ELECTION OF OFFICERS.

The following officers were elected for the ensuing year:—John Dickinson, Esq., President; Samuel Wood, Esq., Vice-President; Dr. Drury, and Mr. J. R. Humphreys, were re-elected Honorary Secretaries.

MEDICAL REFORM.

The following petition to both Houses of Parliament was then unanimously agreed to and signed.

To the Honourable the Commons of the United Kingdom of Great Britain and Ireland in Parliament assembled.

The humble petition of the undersigned, members of the Shropshire Branch of the Provincial Medical and Surgical Association, at their annual meeting assembled.

SHREWETH,—

That the laws at present in force relating to the medical profession are in a most conflicting and anomalous position, and require the interference of the legislature. That there are no less than nineteen sources from whence licenses to practice may be obtained. That there is no uniformity either of education or qualification for like degrees in the three divisions of the united kingdom. That there is no proper system of registration, whereby those who are duly educated, and legally qualified, may be distinguished from ignorant and dishonest pretenders. That the representative system is not sufficiently carried out in the different corporate institutions; and consequently, the profession and the governing bodies are not in that harmonious relation to each other, which is essential to the maintenance of the dignity of the profession, the enlargement of its sphere of usefulness, and the protection of the general interests of its members.

Your petitioners, therefore, pray your honourable House to adopt forthwith such a comprehensive measure of medical reform as in your wisdom may seem meet for the correction of these evils, and for the better regulation of the profession generally. Your petitioners are humbly of opinion, that the carrying out of such a measure will be equally beneficial to the profession and to the public at large.

And your petitioners, as in duty bound, will ever pray, etc.

NAVAL ASSISTANT SURGEONS.

A petition was signed, to be forwarded to the House of Commons, praying for the better accommodation and more gentlemanly treatment of naval assistant surgeons.

THE DINNER.

The members afterwards sat down to an excellent dinner, and spent a most pleasant evening.

SOUTH WESTERN BRANCH: ANNUAL MEETING.

The Annual Meeting of the South Western Branch was held at the Royal Hotel, Torquay, on Wednesday, the 27th ultimo; the attendance was numerous. Before the proceedings commenced, the members partook of a splendid breakfast provided by the members of the Branch residing in the town. At one o'clock, Mr. DELAGARDE of Exeter, the retiring President, took the Chair.

Mr. DELAGARDE, as Chairman, said his duty that morning was very short. He had to thank them for the great consideration he had received during the past year, which, as regarded the future prospects of the profession in this county, he conceived had been exceedingly critical. He trusted the South Western Association had done its duty, and that it had to a considerable extent opened the eyes of the profession to matters which he was convinced would be highly injurious to them. He was happy to congratulate his successor in the presidential chair, which he doubted not would be very efficiently occupied by Mr. Toogood.

Mr. Toogood having taken the chair, delivered an interesting address, from which we take the following passages:

GENTLEMEN,—In addressing you on this occasion, I must claim your indulgence, it being the first time that I have taken any prominent part in meetings of the Association; and never having had either the opportunity or advantage of attending more than one of the anniversaries, my position is a novel one, and my experience of the practice usually observed very limited.

I bid you a cordial welcome to this favoured spot; and to those who now visit it for the first time, it may be desirable to give a short history of the town of Torquay, its statistics, and the advantages of its mild climate, so peculiarly beneficial to invalids, especially to those who have a tendency to pulmonary affections, as well as to point out any object of interest.

The chief recommendation of Torquay is its climate, and the extreme beauty of its situation. Forty years ago it was a fishing village numbering 700 inhabitants; since that time it has grown up into an important town, with a population (at the last census) of 12,000. We have no public institutions of interest, though there are some in contemplation. An infirmary was built two years since, which, although in its infancy, already dispenses much good to the town and neighbourhood.

In pursuing my description of Torquay, I shall avail myself of the labours of my friend Mr. Vivian, who, for upwards of ten years past, has paid close attention and taken daily observations of the temperature, humidity, and other characteristics of the climate; and from those published statements it is proved that "the summer in Torquay is as much cooler than in other parts of England as the winter is milder"; also, that though the fall of rain is sometimes in excess, the number of wet days is below the average, and the humidity of the air is considerably less, as shown by the additional amount of vapour required to produce saturation, which constitutes sensible dampness at any given temperature. The last autumn formed an exception, the fall of rain and number of wet days during the last autumn being far beyond the average of other seasons, and some hardy plants which usually were uninjured in the winter having been destroyed by its unusual severity. According to Mr. Vivian's letter, the annual mortality of the Newton union, in which Torquay is situated, is about one-eleventh below the average of Devonshire, one-ninth below that of the five western counties, and nearly a quarter below the general average of England and Wales. That deaths from consumption (including strangers) are less in this district in the proportion of twenty-eight to thirty-nine, and those from diseases of the liver and digestive organs in the proportion of eight to thirteen, as compared with the same average. These observations show that the mean annual temperature of Torquay is higher than any other place in Great Britain or Ireland; and that this advantage is felt in the cold months, the summers being cooler than at most other places in about the same proportion as the winters are warmer, the climate being more agreeable; that the number of days upon which rain falls is less in Torquay than in any other place in England, it

possesses a drier air than any other place mentioned in the Registrar General's report, and that the east wind is a sea breeze, an advantage peculiar to this coast. But for these and other interesting details I must refer you to Mr. Vivian's little pamphlet on the "Climate of Torquay". It is to be regretted that very erroneous impressions still prevail in the minds of the public with regard to the heat during the summer months, such as that it can only be compared to that of India, though it is well known to the inhabitants, as well as the visitors, that a fire is often as agreeable here as in many parts of England. The superiority of the summer climate is at present satisfactorily shown by the visit of the Grand Duchess of Leuchtenberg, eldest daughter of the Emperor of Russia, shortly to be followed by the Princess Olga, and other foreign families of distinction, induced to sojourn here during the summer months by the favourable report of the Grand Duke of Oldenburg, who passed two summers in this place.

It is a subject of congratulation to the members of this Association, and a proof of its influence being extensively felt, that our example has lately been followed in Ireland, and an association established by the profession there on the model of our own. Our professional brethren of the Sister Kingdom, taking advantage probably of our experience, have also very wisely improved on our plan—and in no respect more so than in sinking the term "Provincial", and in calling their Institution by the more comprehensive title of "The Irish Medical Association". Assuredly, this is a time when it is most desirable to remove rather than to perpetuate unnecessary distinctions in the profession—a time when the whole body of the profession should combine against the inroads of falsehood and empiricism, the grinding injustice of local Boards of Guardians, and the encroachments of wide spreading and indiscriminate medical charity. This is surely a time too, when it is less than ever necessary to keep up a distinction between metropolitan and provincial medical men—now that the rapidity and facilities of communication place all improvements going on in every medical institution in the country within the reach of every member of the profession—whilst the increase and improvement of periodical medical literature, and the full and early information thus diffused of all transactions in the science and practice of medicine, place the advanced knowledge of the day within the reach of all, wheresoever they may be located. The want of libraries is much felt, particularly amongst the junior members of the Association. I would therefore suggest for consideration, whether it may not be advisable to establish one in every district Branch, in which, after a time, a good assortment of monographic and standard works may be found, which would enable members to pursue and continue a systematic course of study, or thoroughly investigate any one branch of medical science. Some steps have already been taken towards the accomplishment of this object in this town, and it is hoped that at no very distant period our efforts will be successful.

NEXT ANNUAL MEETING OF THE BRANCH, OFFICERS, ETC.

Dr. NANKIVELL, of Torquay, moved that the next Annual Meeting of the Branch be held at Plymouth. He hoped that that arrangement would induce their medical brethren in that town, as well as Devonport, to come forward and join their ranks in larger numbers than heretofore.

There could be no doubt in the minds of those who had watched the proceedings of the past year, that the Association had made a considerable step in advance, and that there was a prospect of its being still more largely supported; and he likewise trusted to its being conducted with more spirit and energy, and with better success.

Mr. EDYE seconded the motion, which was adopted.

Dr. SHAPER moved that Mr. W. J. Square be the President-elect, which was seconded by Dr. HALL, and carried unanimously.

Mr. SQUARE, in returning thanks, said he had much pleasure in accepting office, and expressed a hope that their numbers might increase during the coming year.

Dr. BLACK said he regretted the necessity of his having to move the next resolution, as they all felt greatly indebted to the gentleman who had hitherto acted as Secretary. They were sorry he was unable to continue that office, but as he had resigned, it was proposed that Mr. Drake, of Exeter, should be appointed Secretary of the Branch.

Dr. MILLER, in seconding the motion, expressed his regret at the resignation of Dr. Kingdon.

Mr. SQUARE moved the appointment of the new members of the Committee who retire by rotation, which was seconded by Mr. KERSWILL, and carried.

Mr. Edye, Mr. James, Mr. C. Gay, Mr. Barnet, Mr. Gillard, Mr. W. Clapp (House Surgeon to the Devon and Exeter Hospital), Mr. Dakin, Mr. Haydon (Bovey Tracey), and Mr. Bigg, were elected new members.

CASES AND COMMUNICATIONS.

Mr. BOND related a case in which a young woman was delivered of a healthy child, and subsequently when he imagined she was going on well, she gave birth to a second, which was partly decomposed, and appeared to have been dead almost three weeks.

Mr. SQUARE stated a similar case which he had met with about ten years ago.

Mr. TOOGOOD, sen., commenced an interesting discussion on the best mode of stopping hæmorrhage in the hand, whether by tying the palmar artery or by flexion of the arm. Eminent authorities were named in favour of both plans.

MEDICAL REFORM BILL.

The following resolution was passed:—

That this Meeting, in recognising the services of the Committee appointed at a meeting of the profession at Exeter, on the 26th April, to watch the progress of a Bill for Medical Reform, request them to continue to direct their attention to that subject, and suggest that the Committee may with advantage add to its numbers Mr. Square, of Plymouth, Mr. Mackenzie, of Tiverton, and Mr. Toogood, of Torquay.

Votes of thanks were then passed to Dr. Kingdon, Mr. Delagarde, and the President, which were duly acknowledged, and the proceedings terminated.

BATH AND BRISTOL BRANCH.

At the Anniversary Meeting, a committee was appointed to draw up a petition on the

VACCINATION BILL.

The following is a copy of the petition presented by the members in Bath:—

"To the Honourable the Commons of the United Kingdom of Great Britain and Ireland, in Parliament assembled.

"The petition of the undersigned members of the medical profession in Bath and its vicinity,

"HUMBLY SHEWETH,—

"That your petitioners are of opinion, that no bill for the extension of vaccination will be successful, that does not receive the willing and active co-operation of the medical profession, as it is to that body the public must look for the carrying out of any scheme of vaccination.

"That it is the opinion of your petitioners, that vaccination should be compulsory.

"That it is frequently impracticable, especially during the winter, to keep up a supply of vaccine matter from the arm; and that, therefore, it should be permissible to vaccinate from dry matter when fresh is unattainable.

"That the ordinary duties of a medical practitioner render it impossible that he shall be able at all times to be at the appointed place for vaccination at the fixed time; and that, therefore, he should not be subject to any penalties for the occasional omission of this duty.

"That it should be imperative for the person having the care of the child, to bring it on the eighth day after vaccination, for inspection; neglect of which should prevent their receiving a certificate.

"That, whenever the residence of the medical officer is one mile from the vaccination district, the remuneration should be not less than 2s. 6d. each case.

"And your petitioners will ever pray," etc.

METROPOLITAN COUNTIES BRANCH: DEPUTATION TO LORD PALMERSTON ON THE VACCINATION EXTENSION BILL.

Dr. Cormack, Dr. Fraser, and Dr. Semple, waited upon Lord Palmerston on Monday last, as a deputation on the subject of the Vaccination Extension Bill.

The deputation strongly urged upon his Lordship the propriety of delaying the Bill until next Session, more particularly on the ground that the Anniversary Meeting of the Provincial Medical and Surgical Association was appointed to be held on the 10th of this month, when the whole subject would be taken into consideration. The deputation stated, that efficient vaccination was not necessarily to be obtained by making the operation compul-

sory, and that the proposition to leave the machinery of the Act entirely in the hands of the Guardians of the Poor Law Unions was unpopular with the profession.

His Lordship asked various questions, and entered freely into conversation with the deputation. He stated that the request for delay seemed very reasonable; that he thought that Sir John Pakington would be satisfied this session with having had the Bill amended in Committee, and that it would be submitted to the deliberate consideration of the profession. Lord Palmerston stated that he had little doubt that the Bill would, under all the circumstances of the case, be postponed until next Session. He distinctly intimated to the deputation that, in his opinion, that was the proper course to be adopted.

MEDICAL BENEVOLENT FUND.

At the meeting of the Committee, held July 26th, letters of acknowledgment of the sums granted at the previous meeting having been read, the Treasurer announced that the balance due to him was £4 10s.

The following cases were considered and relieved:—

i. The widow of a medical man, now at a training establishment to enable her to become a schoolmistress, so that she may support her family. Relieved several times previously. Recommended by Mr. Newnham and Mr. Toynbee.

ii. An orphan of a medical man, who died leaving four children; she has been an inmate of an orphan asylum, but has not been re-elected; in order to complete her education. The sum of £90 is required to secure her re-election, towards which a grant of £10 was voted. Recommended by Dr. Bernard and Dr. Rogers.

iii. The widow of a medical man who died lately at sea when in charge of an emigrant ship. He left five children wholly unprovided for; the eldest of whom is only five years old. A policy of insurance for £100 was forfeited on account of some informality. Recommended by Mr. I. B. Brown, Mr. Brown of Hammersmith, and Mr. Toynbee. Voted £10.

iv. The widow of a physician who practised in London, and who died lately, leaving seven children. Recommended by Professor Fergusson and Mr. Toynbee. Voted £20:—£10 to be given now, and £10 in January.

v. The widow of a medical man in distress. Voted £5.

Several other cases were brought forward, but they were not taken into consideration, on account of their being inadmissible.

EDITOR'S LETTER BOX.

CHLOROFORM IN MIDWIFERY.

LETTER FROM J. DEANE, ESQ., TO THE EDITOR.

SIR,—Dr. Snow's admirable paper on Chloroform in Labour has elicited a discussion in which all your readers must take an interest. One cannot help admiring the kind spirit in which the opposition is conducted; but it is rather remarkable that not one of the respondents has used chloroform in labour, and therefore not one of them is competent to say one word on the subject. The proposal made in your number for June 21st, is good as far as it goes. It would be desirable to elicit the opinions of competent persons on a momentous practical question; but one element in the qualification to speak, as such, at any assemblage for this purpose convened, ought to be *experience*; and no man ought to utter a word on the question unless he can give the affirmative to the question, "Have you used chloroform in labour?"

The objection based on Scripture is simply amusing. It is certainly said, "in sorrow shalt thou bring forth children"; and it is also said, "in the sweat of thy brow shalt thou eat bread". Thoughtful men do, however, rid themselves of the troubles of life as much as possible. "Five hundred a year, payable in advance quarterly", will considerably relieve a sensible man from the masculine part of the "curse"; and if we could relieve the gentler section of our race of an equal part, or, still better, one or both of the entirety, whether we used science or religion for the purpose, or both together, I do think we might readily and willingly bear the reproach of profanity; but assuredly not from a disciple of Him who went about "doing good". A dose of laudanum or of chloroform will often relieve human agony; it would be droll if neither of them could be used without sin.

piety. As far as I understand the subject, from the observations of others and from personal experience, the sorrows of conception and the many disagreeable incidents of parturition are not affairs for chloroform. It aims only at relieving the last agonies of the last stage of labour.

I believe, however, that opposition to chloroform is the popular side of the question. It is certainly a good way of making thoughtless people think you cautious and trustworthy. The opposition is made chiefly by persons who, not having used it, and who being often men in highly respectable practice, and therefore not having leisure to learn how to use it, and having moreover strong fiscal objections to appearing ignorant or negligent, do more or less unconsciously slide into the evil of opposing what they do not understand. Medical men under such circumstances are in a dilemma. Oracles in their own circles, they wish to let it appear that they know on every medical subject all that is known, and what are they to say to the inquiries of their clients? If they approve, they must use it, and often they must learn its proper mode of application from some of their neighbours, and they must add considerably to the toils of practice; if they disapprove, they must find reasons against it—and who cannot do this against anything? There are reasons even against eating and drinking; for instance, your butcher's bills; but the reasons for eating outweigh the reasons for a perpetual fast. So there may be manufactured reasons against chloroform in labour, but not reasons equal to those in its favour. Its opponents can at any rate parade themselves as models of prudence and of vigilance over the welfare of their patients, as abjurers of all experiments, as enemies of all the weaknesses of humanity, as hardheaded monopolizers of wisdom, and last, not least, as the faithful defenders of the Book of Genesis! Verily, wisdom is with us; and when we die, common sense and religion will die also. Such, Mr. Editor, is the *rationale* of the opposition to chloroform: it is, *ad captandum*, chiefly also, I regret to say, made by men of very honourable position in the profession. The proof which I assign is, that its antagonists have, as a general rule, *never tried it*, and have not the courage to say that they know nothing about it.

I should be sorry to speak much of my experience in the use of chloroform; I have, however, used it, and with much satisfaction. For more than a year, dating from Professor Simpson's first paper on the subject, I used it on the lower animals, and with perfect safety. I kept a common meat-fly eighteen hours in a state of anæsthesia under a wineglass, leaving him once for four hours, and frequently for a shorter term. Among other preliminaries before using it on the human subject, I rebroke a badly united fracture in a dog's leg, and reset it under profound anæsthesia, and then kept him asleep for one hour without any bad result. A neighbour's donkey had fungus hæmatodes of the eye; I removed the eyeball under chloroform. Several of the lower animals were thus experimented on before trying it on the human subject. I name these incidents to show that the advocates of chloroform are as cautious as its opponents; for I presume we have all resorted to similar expedients. I have since employed it in operations on the human subject, and have seen nothing like an accident. I have not used it less than one hundred and fifty times. You must know, that no accidents have happened in the Edinburgh and Glasgow Infirmarys, where it is administered according to the rules laid down by Professor Simpson. One rule is, that where muscular action precedes loss of sensation, you must desist. In most cases where death has occurred, the first action has been on the muscular system, and yet it has not been discontinued; so the newspaper reports themselves have stated. Sometimes another rule has been infringed: the chloroform has not been sufficiently diluted with atmospheric air. In every administration of chloroform, a great deal ought to be wasted. The defence has been, we used only so much, naming a small quantity. The truth is, that it has been breathed undiluted, and the patient has been suffocated.

"He who would win the race must guide his horse,
Obedient to the customs of the course."

If we want the benefits of chloroform, we must be so far docile as to use it according to the instructions of its discoverer; and if we err from unteachableness, let us blame ourselves, and not the knowledge which we will not acquire. These and other principles I have carefully adopted in the use of chloroform: I have resorted to it seventeen times in labour, with the best results.

I had nearly resolved to have nothing to do with it in labour, merely because I would not face a prejudice, when the following incident changed my intentions. One of my patients,

a young woman in her first labour, after nine hours of grinding pain which she had borne patiently and without sending for me, was suddenly seized with severe cramp in the gastrocnemii and inside the soles of the feet; she experienced at the same time a sudden cessation of uterine pain. She sent for me; I found the os uteri dilated to the size of a crown piece, thick and soft; the vagina was flaccid, the pelvis large. I predicted favourable progress, and probably a speedy delivery, if she had bearing-down pains. There being what the older writers call metastasis of labour, laudanum was advisable, but I considered it would be slow in its action; and her pain from muscular cramp was so severe, that I wished a more immediate remedy. She was starting round the room and screaming like a maniac, although a young woman naturally of great fortitude. Who could forbid chloroform here? I administered it, with instant relief from pain, and in about ten minutes she was in an imperfect sleep. A groan was occasionally heard; a distinct and powerful forcing was felt *per vaginam*, the membranes projected, the caput succedaneum was formed; I kept up the chloroform at intervals for more than an hour, and the child was born. In this case we had the forcing of labour without the pain, and suspension of sensation without unconsciousness; she knew all that was going on around her, had heard a mumbling of voices occasionally, had been agreeably spellbound; had had no pain, and declared "the stuff was worth one thousand pounds", and that no woman ought to be confined without it.

The result of this case, together with my former experience, was a very favourable opinion of chloroform in labour. I did, however, blame myself on one point, which I resolved in future to guard against. I did not consult her friends beforehand; and although they were all content, and even delighted with it, and grateful to me, I considered there was a slight omission. Unestablished remedies should not be used but with the consent of friends, after full explanations. When a medical man is consulted, medical science is consulted; and what is not usage established and approved by a vast majority of the profession, is more or less non-medical. Since that time, I have worked this principle into the following rule. Unless pre-engaged by the patient for at least one month beforehand, and approved by the husband and friends, chloroform has been refused in the kindest way possible, but often with much difficulty. I have, altogether, used chloroform seventeen times in labour; and not one of my patients has disliked it. I have had no obstetrical case where muscular action has prohibited it, although I have had three non-obstetrical, where slight muscular quiverings have led me to desist. All these cases have been simple uncomplicated labour, where I have used it solely to relieve pain. I have considered that, if the patient and her friends wished it, there was sufficient medical authority to sanction its use. My experience, as far as it goes, proves its safety in the human subject generally, and in these cases in particular. My impression also is, that labour proceeds quicker, there being less resistance in the soft parts; and that patients feel better after anæsthetic labour, I am quite certain. Pain is exhausting; it is as much an expenditure of the system, *for the time*, as loss of blood. After labour, under ordinary circumstances, how faint you find your patient; how thoroughly "worn out", to use her own expression. In a profuse perspiration, with a haggard countenance, a voice almost inaudible, your involuntary and untaught impression is, that she has gone through almost mortal agony. Where chloroform has been used, your patient, having eluded the last and worst stage of her "sorrow", looks just as comfortable as if she had been confined a fortnight. Medical men, who have seen these things, will not pronounce the statement hyperbolic; and although some of them may, for reasons of policy, decline "to do likewise", yet, when asked their opinions in the fabled temple of truth, where men say what they think, not one among them will fail to give a favourable reply. There are reasons not strictly medical, which will sometimes prevent its use: where you suspect a bad result you do well to shelter yourself by declining it. One of my patients, to all appearance in good health, except that she had a bronchocele, wished chloroform, but I declined it, because of the too frequent connexion between this morbid condition and cerebral affections. I did not assign my reason. She did well during her confinement; but five months after, suddenly became insane, and remained so for several weeks. I have very little doubt that I here escaped an unjust censure, both on myself and on chloroform. Some time ago, I was requested to remove a scrofulous finger under anæsthesia. I agreed to do so as soon as an extra servant was hired, which was to be in about ten days; but, before the interval had expired, meningitis with profound stupor set in, and my

patient died. Suppose chloroform had been used the day before? These are the real, and, I think, the only difficulties to deal with in the use of chloroform. I have been so far timid under other circumstances rather unpromising, as not to use chloroform when requested, and perhaps required, thus yielding not a little to the fear of public opinion and allowing reliable suffering to be unrelieved, lest a useful expedient should be unduly blamed. These patients will do better for themselves under chloroform, but, being more likely to go wrong than others, they will, without chloroform, do better for the character of the attendant. With the chloroform they have a better chance of recovery; but, without it, the surgeon has a better chance of saving himself, by attributing death, when it occurs, to its true cause. Here we incur a great responsibility in using chloroform, because the only differential fact seen by the public will be chloroform, and we are sure, in the face of an adverse result, to be blamed for using it, and discredited when other special causes are assigned. In critical cases, I regret to say, I have not yet been sufficiently indifferent to public opinion, but recent events, adding to the names of Simpson and of Conquest, the distinguished names of Locock, Fergusson, Snow, and others of reputation, have so biased professional authority in favour of chloroform in labour, that we are bound to look upon it as sanctioned by a large majority of the professional talent of the kingdom. It is probable that the warm advocates on both sides are wrong. To argue that it should always be used, or that it should never be used, are both extremes. I think all who have resorted to it with proper caution will pronounce it safe, and then it will become a woman's fancy "to be or not to be" according to the predilections of the patient. To relieve pain seems to be one of our duties; and it is only for those who have never felt them, to speak lightly of the horrors of parturition. I honour the name of Simpson, and I look on his discovery as a gift to society, fully equal to any ever made by any one man in the profession, unless, perhaps, we except the name of Jenner alone.

I am, etc.,
J. DEANE.

CHLOROFORM IN MIDWIFERY.

LETTER FROM JOHN AUDLAND, ESQ., TO THE EDITOR.

SIR,—I cannot think that Dr. Simpson's paper is conclusive in favour of the general use of chloroform in midwifery practice. Take, for instance, the portion respecting its employment in forceps cases. Now there is no question, that accoucheurs like Dr. Simpson, practising in the metropolitan and large provincial towns, become, in consequence of having extensive consultation practice, expert in the use of the forceps and other instruments. They acquire a mechanical dexterity which country practitioners, although they may be well acquainted with the anatomy of the pelvis, cannot possibly do. Such practitioners may not require, they may even despise, the aid derived from the feelings of the patient, but I apprehend that is not the case with the generality of country practitioners.

A country practitioner is called to a case, some miles from home, and from the residence of a professional friend. The case is tedious, the pains occasionally strong, and then, for a few hours, slow and weak. He carefully watches the case, soothes his patient, and encourages her and her friends. Owing, perhaps, to the head being large, to rigidity of the soft parts, or to a slight contraction of the pelvis, or to some other cause, the natural efforts are ineffectual. He explains this to the patient and her friends, tells them that it is possible that by patience, etc., all may yet end well, but that there is risk in delay; that the vital powers may give way, and that if instrumental assistance be not had recourse to, she may possibly sink. The woman and her friends are alarmed at the mention of instruments; but the practitioner assures them that the instrument he is about to use will neither injure the woman nor child. He explains to them, that it is merely intended to assist the natural efforts, and promises the woman that he will desist when she experiences severe pain.

Now, I say that a practitioner so circumstanced, alone, often without adequate assistance, even to keep the woman in a proper position, has sufficient upon his hands, without the additional anxiety he must have if chloroform be administered.

But, supposing there were no additional risk, supposing that chloroform could be administered as safely as a dose of opium, is there no fear that the practitioner might be tempted to use more force than is prudent; that, for the want of the safeguard of the woman's feelings, "he might bruise, lacerate, destroy"? Is there no fear that temporary relief from pain, might be pur-

chased at the risk of permanent suffering and misery? And if so, is not great caution needed; ought not the subject to be well considered in all its bearings, before we habitually employ chloroform in ordinary midwifery practice?

Dr. Simpson asks, if a surgeon, in taking up a large artery, does not discriminate between the artery and its attendant nerve, by his anatomical knowledge, and not by the feelings of his patient? Granted. But yet, are there no instances where an accomplished anatomist and surgeon has only been made aware by the cries of his patient, that the nerve has been included in the ligature? One such case, I think, I myself have seen. Are there not other cases in surgery, in which the sensations of the patient are of service to the surgeon? Take, for instance, the introduction of the catheter. Supposing that in every case of stricture and retention of urine, chloroform were administered, would there be no fear of too much force being used; no danger of a false passage being made? Are not practitioners constantly obliged to withdraw the instrument a little, on account of the exclamations of the patient? And may not the sensation of pain in these cases, as well as in those of instrumental midwifery, be frequently *conservative*?

Then, again, take cases of flooding. We know that occasionally copious flooding suddenly takes place, either before or after the birth of the placenta, which requires the greatest promptitude on the part of the attendant. Supposing it were to occur whilst the patient were under the influence of chloroform, would it not add to the anxiety of the practitioner? From what we know of the effects of chloroform on the system, would the hæmorrhage be more promptly checked? Would the system be as susceptible of the application of cold? Could brandy be as readily administered?

Now, I am considering ordinary cases, which occur in country practice, when only one practitioner is present, and when the whole responsibility devolves upon him. And I ask the question, Would the constant use of chloroform in midwifery practice be attended with beneficial effects, or the reverse?

I consider that there is a great difference between using means to relieve the pains of "headache, colic, of sciatica, of pleurodynia, of gout, rheumatism", etc., and administering chloroform in ordinary cases of midwifery. In the former class of cases, we endeavour to remove the morbid condition upon which the pain depends. In the latter, we render the person unconscious of pain, by administering a powerful inebriant.

It would be presumptuous in me to set my opinion against so eminent a physician as Dr. Simpson; but I must confess that I think there is a good deal of begging the question at issue in his paper. The question is, not whether it is the part of true wisdom to take advantage of the discoveries of science, but whether the general use of chloroform in midwifery would be advantageous or not.

I am, etc.
Tintern, near Chepstow, July 16th, 1858.

JOHN AUDLAND.

CHLOROFORM IN MIDWIFERY.

LETTER FROM SAMUEL BEECROFT, ESQ., TO THE EDITOR.

SIR,—After the perusal of Dr. Simpson's letter to Dr. Meigs of Philadelphia, inserted in our *Journal* of the 8th inst., I confess that my mind is as much unsettled as to the propriety of using chloroform as it was previously; for not even Dr. Simpson's logic does away with the necessity of having facts recorded to guide us in forming an opinion. These facts should be supplied, if possible, by parties not having the same interest in supporting the question as the discoverer, as being more likely to be free from bias, and therefore more to be trusted. Dr. Simpson cannot be offended with this remark, since he tells Dr. Meigs that his rule, while applying the forceps, of inquiring whether pain is produced, is "an after thought, only sprung up since the practice of anesthesia was proposed."

It is to me extremely remarkable that, after chloroform has been used for so many years, and so generally, in our hospitals, no return has been made, stating the number of cases in each hospital in which it has been used, and also giving their termination; for it is only by such a return that we can at all arrive at a sound conclusion on the subject.

Dr. Simpson states, that in amputations, the success has been much greater under the use of chloroform; but I hear of other parties holding the contrary opinion. In this statistical age, it is so easy to form a table supporting anything new, that any statistics brought forward ought to undergo a most rigid scrutiny, prior to being received as correct. I am sometimes inclined to think, that we place too much stress on the advan-

tage to be derived from the absence of pain under the use of chloroform, in surgical operations, in preventing shock to the system; and to me it seems very questionable, if the pain of an operation does exercise the power assigned to it in the production of shock—at all events, to the extent generally attributed to it. Indeed, some think that the knife has acted sometimes as a stimulant. And it appears probable, that the pain of an operation may be of service, in telegraphing to these conservative powers of life what is taking place, and thus rousing into activity the *vis medicatrix naturæ*, to repair the injury and equalise the circulation, especially after the change produced on it by the loss of the limb. Two of the most severe cases which I have read of in our Journals, almost lead me to infer such to be the case; for, in these two cases (I believe patients of the Bristol Infirmary, in whom amputation of both legs was performed), in one chloroform was used, and the patient died; while the other patient, who was suffering from a greater degree of collapse, did not inhale chloroform, and he recovered. I cannot find the Journal in which these cases are recorded; but I believe the above account to be correct. Again, in the *ASSOCIATION JOURNAL* for July, Mr. Falloon gives 310 cases of midwifery; and whether it be owing to his use of chloroform, or from some other causes, I am sure, after having examined the same number of my own cases, and after making inquiries from my medical friends, that his mortality among children, and the number of cases of *post partum* hæmorrhages and retained placenta, are much above the average.

With respect to the letter of Dr. Simpson to Dr. Meigs, I shall make no other remark, than that I am astonished that any person, who has seen any midwifery, can be bold enough to assert that "pain is non-essential for the successful completion of natural labour". Dr. Simpson has often startled the profession by astounding statements; but I fancy that many of us will not be led to use chloroform in labour, by such reasoning as the above.

But the question of the propriety or impropriety of using chloroform can never be settled by letter writing. What is required, is a faithful account of its use in every case admitted into our hospitals and obstetrical institutions; and, if the benefit from its use preponderates much over the evil, the profession can at once decide, and set the matter at rest. Until its benefits be proved, I, for one, shall be very cautious in using chloroform, although our Journals may contain communications, stating that large doses may be administered with impunity. In the *Lancet*, a few weeks ago, there was a case related of a child, under two months of age, having inhaled, in sixty hours, about sixteen ounces of chloroform: and yet the child still lived! Yet I know that, a short time previously, in the same city (Manchester), a strong man was killed by a few drachms of it. It is the recollection of such cases, and not any inherent dislike to its use, that makes us anxious and afraid of using chloroform; for I believe that no discovery was ever received with so much delight as that of chloroform; and it is painful to find our early anticipations so greatly disappointed.

I am, etc.,

SAMUEL BEECROFT.

Hyde, near Manchester, July 1853.

THE SABBATH.

LETTER FROM WILLIAM ALLISON, ESQ., TO THE EDITOR.

SIR,—As a member of the medical profession, allow me to thank you for your article in the *JOURNAL* of July 1st, in reference to the opening of the Crystal Palace on Sundays.

We all wish for the bodily and spiritual welfare of the poor; although some of us differ in opinion from others as to the best means for promoting those blessings. With you, I do not agree with Dr. Forbes in thinking, that by withholding from the working mechanics an opportunity for crowding together in the Crystal Palace on a Sunday, they will be rendered more liable to meet in alehouses, to fall into a state of constrained idleness and listlessness at home, or to have their brains exhausted and their thoughts weakened and confused by an excess of religious study, or of religious exertions. The poor may derive as much advantage from being dispersed abroad in parks or open places with their children, as from congregating in the Crystal Palace, when not resting at their homes in their family circles.

The members of the medical profession are notoriously said to be an atheistical body; and I think that your writings are calculated to defend them against that unjust reproach, and to uphold their characters as Christians.

I am, etc.,

W. ALLISON.

East Retford, July 2nd, 1853.

THE SABBATH.

LETTER FROM CHARLES COWDELL, M.D., TO THE EDITOR.

SIR,—Having long striven to vindicate our honourable profession from the commonly believed allegation of a tendency towards infidelity, it rejoices me to witness a practical refutation of the calumny in a movement on so large a scale as that reported in your columns, as having been made in the metropolis to defend the poor from invasion of their rights, and the nation from certain demoralisation, by legalised desecration of the Lord's day.

This joy is, however, tempered with unaffected sorrow to see one, for whom I entertain sincere regard and esteem,—one who has devoted great talents to the improvement of our profession, advance single-handed to the charge in defiance of this phalanx.

Like you, I do not advocate a puritanical observance of the Sabbath, (though no one has ever repented of its too strict observance); and, like Dr. Forbes, I do advocate the right of the poor man to his weekly holiday. But, while it is conceded that God made the country, and made it too for the refreshment of the toil-worn townsman, I maintain, that the same God made, or gave the fourth commandment, which forbids that toil-worn man to work horse or ass, or servant—male or female, and if so, a railway train, omnibus, or steamboat, to take him hither and thither on Sunday.

To be more particular. I apprehend that the whole force of Dr. Forbes's charge against unphilosophical and illogical medical men, and the whole grounds of his defence of poor men's rights, so far as this matter is concerned, are contained in the following passage from his communication to the *Journal*: "It is truly at once humiliating and melancholy to observe—in these later years, when we might reasonably expect a more philosophical consideration of such subjects—that there is a growing disposition among the clergy and the upper classes generally in England, and still more in Scotland, to curtail such simple and natural enjoyments of the poor on their only holiday, the Sunday. To say nothing of the necessity of such relaxation on the score of mere bodily health, the advocates of this system seem entirely to overlook the principle of man's nature, which renders the occasional remission of activity necessary for the perfect exercise of all voluntary functions, and most of all, the functions of the brain." We do believe that "the occasional remission of activity"—in other words, that regular periods of recreation—are "necessary". But then we ask Dr. Forbes to show us that it is necessary that such recreation should be had only on the Sabbath, or, as he says, "*on their only holiday, the Sunday*". Only during the last month, a noble example has been set by a large business firm in London (Messrs. Barclay and Co., the brewers, and I am informed that Messrs. Fox and Henderson, of Birmingham, have yielded the same benefit to their fifteen hundred workmen), of giving up the Saturday afternoon to their workmen.* This is the true solution of the problem; for it is the mammon maw of the money seekers, exacting the utmost quantity of labour from their slaves, which drives the artisan to Sabbath desecration. Let the legislature step forward and secure to the poor man his right, without touching that portion which God has reserved as His own; and we trust Dr. Forbes will be satisfied as well as ourselves; aye, and the poor man too, who, he says, never goes to church but once on a Sunday, will then perhaps set a better example than many of his wealthier fellow men. On the other hand, let Sunday public amusements be legalised, and the stigma which Sir Thomas Browne, in his *Religio Medici*, endeavoured to prove was undeserved—"ubi tres medici, duo athei"—will soon probably be true, not only of physicians, but of all other classes of Englishmen.

It is implied, that those medical men who have contributed to this movement are illogical and unphilosophical. Be it so. Religion is the foundation of philosophy. God is truth. And philosophy is only true so far as it conforms to Christianity.

In the words of *Evening Thoughts*, "Philosophy is the statue, Christianity is the man: philosophy is the cold marble Laocoon struggling with the serpents; Christianity is the man himself struggling with the outer world."

I am, etc.,

CHARLES COWDELL.

Dorchester, July 5, 1853.

* We could add many other firms to this list. There is a hopeful progress in the right direction.—EDITOR.

PETITION FROM MEDICAL PRACTITIONERS IN
EDINBURGH, AGAINST OPENING THE
CRYSTAL PALACE ON SUNDAY.

LETTER FROM B. BELL, Esq., TO THE EDITOR.

SIR,—The petition from medical practitioners in London, against the opening of the Crystal Palace on Sunday, was hailed with much satisfaction by many of the profession here. It was thought to be a right and seemly thing to strengthen the hands of our brethren in the metropolis in an object so laudable; and, accordingly, a petition has been drawn up and largely signed by the practitioners in Edinburgh and Leith, including many of our most eminent men, and several of the professors. The signatures amount to above one hundred, which, considering the relative populations of the two cities, is not discredit to the northern metropolis.

I am, etc.,

BENJ. BELL.

8, Shandwick Place, Edinburgh, July 21st, 1853.

*To the Honourable the Commons of Great Britain and Ireland,
in Parliament assembled.*

The petition of the undersigned physicians, surgeons, and general practitioners, resident in Edinburgh and Leith,

HUMBLY SHEWETH,—

That your petitioners believing in the Divine institution of a seventh day of rest, and recognising its remarkable adaptation to the constitution of man, and its absolute necessity to his health, both bodily and mental, cannot but view with anxiety and alarm every new encroachment upon the Sabbath rest of a large and increasing section of our fellow countrymen.

That every addition made to the number of public amusements on the Sabbath, is not only inconsistent with the spirit of God's word and the habits of our country, but leads inevitably to an increased amount of locomotion by railways, steamboats, and vehicles of all kinds; that this cannot exist without numberless forms of entertainment and traffic; and that the whole complex system necessarily involves the Sunday labour and toil of many thousand persons throughout the land, who are thus systematically robbed of their Sabbaths, under the plea advanced by so called philosophers and philanthropists, that they are ministering to the simple and natural enjoyments of the poor on their only holiday.

That the proposal to open the Crystal Palace at Sydenham on the Sabbath, if carried into effect, will add to those evils on a prodigious scale, besides acting as a wedge for other and grievous inroads upon the sanctity of the poor man's day of rest.

That your petitioners, fully alive to the importance of country air and relaxation to the physical health and intellectual progress of the working classes, would anticipate great advantages from such places of amusement and instruction as the Palace at Sydenham, if the weekly Sabbath were kept inviolate, and a half holiday conceded by employers to their people, as in Manchester, and to some extent in Glasgow, on one of the six working days of the weeks.

May it, therefore, please your Honourable House to refuse your assent to any measure calculated in any way to set aside the law actually in force, and to legalise the opening of the Crystal Palace and its grounds for gain on any portion of the Lord's day.

And your petitioners, as in duty bound, will ever pray, etc.

PETITION FROM THE MACCLESFIELD MEDICO-
ETHICAL ASSOCIATION AGAINST OPENING THE
CRYSTAL PALACE ON SUNDAY.

LETTER FROM T. B. KENDERDINE, Esq., TO THE EDITOR.

SIR,—The subject of the opening of the Crystal Palace on Sundays having been lately much discussed in your pages, with a view to strengthen your hands in what I conceive to be the admirable line you have adopted with respect to it, I beg to forward you a copy of a petition promoted at the last meeting (4th instant) of the Macclesfield Medico-Ethical Association, and shall feel obliged if you will give publicity to it, and express the hope that others may be induced to follow the example set by our professional brethren in London.

I am, etc.,

THOS. BRUTTON KENDERDINE,
Hon. Sec. to the Mac. Med.-Eth. Assoc.

*To the Honourable the Commons of the United Kingdom of
Great Britain and Ireland, in Parliament assembled.*

The petition of the undersigned practitioners in medicine and surgery, resident in Macclesfield.

HUMBLY SHEWETH,—

That your petitioners, recognising the Sabbath as of divine institution, regard with apprehension the efforts which are in progress, in certain quarters, to secularise its character, under the sanction of a legislative enactment.

That deeply impressed as your petitioners are with the conviction that the health of the community depends very materially on the morals of the people, and, with the fact, that the frequenting of places of public resort on the Sabbath, for the sake of amusement, is a fruitful source of moral evil and licentiousness, tending, in no insignificant proportion, to an increase of disease, and of the ratio of mortality; they earnestly deprecate any measure which, under colour of legislative authority, would be likely to open the flood-gates of dissipation and immorality through the length and breadth of the land.

That an Act of Parliament, like that which is contemplated by the advocates for the opening of the Crystal Palace on the Sabbath—framed, ostensibly, for the purpose of affording facilities for public recreation—involving, as it necessarily must, the principle of coercive employment (inasmuch as it would be a virtual surrender of the sacred and indefeasible right of every one to exemption from positive labour on that day), would, in all probability, seriously disturb the existing social relation of master and servant, as it would leave every employer at liberty to exact from his dependents the same amount of service which they had been accustomed to render only on the other days of the week.

That on these grounds your petitioners humbly conceive that the wise and benevolent purposes of the Divine Being in the institution of the Sabbath—if they be regarded simply in a physical point of view—would be frustrated by the concurrence of the legislature in any proposal which would lead to its general desecration on the one hand, or to its secularization on the other.

They therefore implore your Honourable House to withhold your support from any project, which, by compromising the moral relations of the Sabbath as embodied in the Decalogue, would deprive the community of the only guarantee which is thereby furnished for its perpetual observance as a day of repose from the exhausting occupations of the other days of the week.

And your petitioners, as in duty bound, will ever pray.

POOR LAW MEDICAL RELIEF: SUGGESTIONS FOR
ITS IMPROVEMENT.

LETTER FROM C. P. COLLINS, Esq., TO THE EDITOR.

SIR,—I have frequently considered the state of the poor and medical officers under the Boards of Guardians, with a view to the relief of both; and, should you think with me, that good may emanate from the following suggestions, be pleased to give this a place in the Journal.

I begin by asking, if it be not the duty of the state to see that its poor are in every way properly provided and cared for? Taking this for granted, I then say, Parliament is bound to frame laws accordingly; and, as the present poor law is in many instances faulty and inadequate, I would suggest that, with a view to put a stop to the frequent sources of disagreement between medical officers and boards of guardians, by which the poor eventually suffer, in any bill to be introduced, relative to the poor law, into Parliament, a clause be inserted, naming what charges shall be made for the future by medical men, for attendance on the poor; and this can well be done by the per case system, with so much for mileage in country districts. If the law was thus altered, the poor would have this benefit, that they might employ any medical man in their district or union they preferred; and who can deny that this would be a great relief to them? It would also do away with what is now considered by some as a stigma, the name of *union surgeon*. All would be union surgeons; and those who chose to decline a case when sent them by the proper authorities (the relieving officer or overseer), might do so, and the applicants take the orders to the medical man next preferred by him. A consultation fee should also be added, with certain restrictions and regulations; for why should not the poor have, in this respect, the same chance of benefit as the rich? As a union surgeon, it has occurred to me—and I doubt not, to others similarly circumstanced—to have under my care patients for months, without receiving relief from the treatment adopted; and why, in such cases, because the patients are poor, should they be deprived of the benefit of consultation? Care should be taken that none but properly qualified medical men, according to the rules at present laid down by the Poor-law Board, be employed, which, I am sorry to observe, are not faithfully carried out. A list of such should be furnished to each board of guardians, by authority.

That the above could be carried out with little or no difficulty, if taken up in a proper spirit, I am confident; and that it would be for the advantage of all concerned, is, I trust, equally evident. The poor, who are now frequently neglected by the medical officer, and often obliged, in cases of accident, etc., to await his return home for hours, might at once be relieved by a choice of medical men; and the country would have the satisfaction of knowing that their poorer brethren were properly cared for; and what, in my opinion, is of nearly equal advantage, the union surgeon would cease to exist, and we should hear no more of the disgraceful conflicts continually occurring between boards of guardians and medical men. I am, etc.,

CHAS. PALKE COLLYNS.

Dulverton, Somerset, July 18th, 1853.

P.S. Since the above was written, I have read with great surprise the speech of the Chief of the Poor-law Board, as given in the *Times*, in answer to Mr. Miles. I can only say that either the hon. gentleman or the reporter is incorrect, for we have in the Dulverton Union a case of a medical officer, without the double qualification spoken of, elected by the guardians, and sanctioned by the Poor-law Board, so lately as April last. To this the attention of the Poor-law Board was directed.

C. P. C.

THE VACCINATION MEASURE, AND THE INSULT TO THE PROFESSION BY ITS PROMOTERS.

LETTER TO THE EDITOR.

SIR,—The Vaccination Extension Bill has passed through Committee in the House of Commons with its faults and imperfections entire. The remonstrances against it, the threatened opposition of Messrs. Frewen, Brady, and Strickland, have been so feeble, that there has not even been a single amendment. It has been universally condemned; and yet no voice has persisted in disapproving it; and the vain empty words which have reached the House have been contemptuously passed over. How is this? Echo does indeed answer—How? The profession is never consulted on any hygienic measure; and as to their interest—Pshaw! How absurd to think that Parliament can attend to anything of so little consequence!

I have endeavoured to obtain some concession from the promoters of the Bill as to the following proposals, which I will conclude by laying before your readers.

I. That the Bill must have reference not only to those who are to be born, but to *all* who have never been vaccinated, or have not had small-pox; and that the duty of giving notice to the parents or guardians should devolve on the vaccinator, and not on the registrar.

II. That the Registrar General, and not the Poor Law Guardians, should superintend vaccination.

III. That the fee should be 2s. 6d. in town, and 3s. in rural districts.

Surely it behoves the Vaccination Committee of the Epidemiological Society to remonstrate against such a futile and illiberal piece of legislation. I am, etc.,

A COUNTRY VACCINATOR.

Somersetshire, July 27th, 1853.

BREECH PRESENTATIONS.

LETTER FROM R. U. WEST, ESQ., TO THE EDITOR.

SIR,—Since sending off the statistical paper published in yesterday's *Association Journal*, I have read your report of a meeting of the Edinburgh Medico-Chirurgical Society (p. 646), in which it is stated by Dr. C. Bell, that the mortality among children in breech and feet presentations is very great, as much as one in three or four cases, in consequence of the pressure on the funis during the passage of the head. And I have before seen similar statements. But I do not think that the average mortality can be really so great as that, unless where there is very bad management. The presentations of breech or feet, in my practice, have been fifty-seven in number, and of the hand or arm, requiring turning, nine. [I have had one case of breech presentation, and one of the head, since I made up my paper.] The total number delivered with the pelvic end of the child first was sixty-six. Deducting from this number, fifteen still births from other causes, viz., nine *premature putrid* fœtuses, two where the funis had been prolapsed some time before my arrival, one with *placenta prævia* and *prolapsed funis*, one a midwife's case of arm presentation, and two the monstrous twins,—we have fifty-one footling or pelvic births, without any element

of danger but the one in question. Of these fifty-one, three only were still-born; but, as one of these still births occurred in a case where I was called upon to deliver the head for a junior practitioner, after the body had been born some time, the foetal mortality from delay in the delivery of the head, in the fifty cases for which I am fairly responsible, will appear to have been exactly in the proportion of one in twenty-five. As my two still births were both presentations of the feet, there would appear to be in that fact some confirmation of the opinion held by writers, that, *cæteris paribus*, footling are more dangerous than pelvic births. I am, etc.,

R. U. WEST.

Alford, Lincolnshire, July 30th, 1853.

THE PROPOSED MEETING OF PROVINCIAL PHYSICIANS.

LETTER TO THE EDITOR.

SIR,—In your number for July 22nd, I see an advertisement announcing a meeting of provincial physicians appointed to be held at Swansea, during the Association meeting. I fully intend to be there, for I think the time is at hand when we ought to unite to form a permanent Association to look after the interests of our important, but strangely divided body.

The questions of the stamp duties, the indiscriminate relief afforded to all who apply at our hospitals and dispensaries, the evils of the system of gratuitous advice, and the suppression of disgusting advertisements, are all subjects which peculiarly require notice and discussion by provincial physicians.

I am, etc., M.D. EDIN.

July 29th, 1853.

NEWS AND TOPICS OF THE DAY.

MIDLAND CIRCUIT: LEICESTER.

(Before Mr. Justice MAULE and a Special Jury.)

LAMERT V. DAWSON AND ANOTHER.

Mr. Macaulay, Q.C., Mr. Mellor, Q.C., Mr. Serjeant Miller, and Mr. Hayes, appeared for the plaintiff; Mr. Field and Mr. Brewer for the defendant.

This was an action of libel brought by the plaintiff, who, under the name of J. L. Curtis, practises in London as a doctor for a peculiar class of cases, though not a licensed medical practitioner, against the defendant, Dawson, who also devotes his chief attention to the same description of cases, but is a licentiate of the College of Physicians, and a member of the College of Surgeons.* The libel complained of was contained in a book written by the defendant Dawson, and published by the other defendant, and was in the following words:—"I have been repeatedly consulted by patients, who complain of having paid these advertising people large sums of money, and I have at this moment a gentleman under my care, sent to me by Mr. B. W. Hutchinson, of Sidney Street, Cambridge, in consequence of suffering from ———. He gave one of these persons a bond for £1,000, payable on his coming of age. I have also another sent to me by Dr. Chapman, of Grosvenor Street, Grosvenor Square. This gentleman is proceeding against Curtis, the author of *Manhood*, for a similar fraud. The case was set down to be tried on the 6th of this month, but Curtis prevented the trial coming on by refunding, at the last hour, the money and paying the costs. The case had not been settled more than a few days when Dr. Henry Bird, of Chelmsford, sent me a patient who had the misfortune to fall into the hands of the same party. It has rarely occurred to me to see a person suffering more intensely from mental anxiety than this unfortunate patient, in consequence of a peremptory demand from Curtis for the payment of a part of the bond which he had obtained on the promise of a cure."

The defendant, in his plea, alleged the truth of the libel, and mentioned the names of two persons said to have been defrauded of their money by the plaintiff by promises of cure. The plea also set out the advertisement of the plaintiff's book, which is to be seen in the newspapers almost every day (*Manly Vigour*, etc.), and alleged that, by means of that advertisement, the plaintiff induced these persons to come to him

* We cannot find Dawson's name in the official list of the College of Physicians. Editor.

for advice. On the part of the defendant they were called as witnesses; and it appeared that one of them had, upon the advice of the defendant, sued the plaintiff in the Westminster County Court, to recover back a sum of about £80, which had been paid to him for his attendance; and that before the hearing of that case the present plaintiff compromised it by paying the sum of £43 for debt and costs.

These witnesses, however, failed to establish that the plaintiff had undertaken to cure them as the consideration for the payments to him; and from one of them, indeed, the plaintiff obtained only an I O U for £25, but no money.

The plaintiff himself was not examined as a witness, but Dr. Dawson was; and he stated that he had acted upon the information of the two persons who had been sent to him by Dr. Chapman and Dr. Bird, after they had been attended by the plaintiff, and he had failed to cure them. He was cross-examined as to the authorship of certain pamphlets, which contained passages very encomiastic of Dr. Dawson's skill, purporting to be written by "J. Teevan, B.A.," and denied that he was himself the author of them; he admitted that he knew who "Teevan" was, and that the name was an assumed one; but he declined to say who he was. He was also cross-examined as to his violation of professional confidence in bringing his patients forward as witnesses—conduct which he had strongly condemned in his book; but he stated that the witnesses had volunteered their evidence, and they themselves substantially confirmed that statement, though their consent did not appear to have been expressly obtained before their names were inserted in the plea. The cross-examination went, also, to other matters affecting Dr. Dawson's mode of treatment; but nothing material was elicited from him, and the subject is not one very fit for public discussion.

The learned counsel for the defendant commented severely upon the absence of the plaintiff, as well as upon the indecent character of the book of which he was the author, and vindicated the defendant from any imputation of malice; contending that the libel was a simple statement of facts which had been revealed to him, and which he felt bound to publish.

The learned Judge, in summing up, intimated to the jury his opinion that the justification was not strictly proved, inasmuch as it did not appear that the plaintiff had promised a cure; and he left to them the question of damages.

The jury almost immediately returned a verdict for the plaintiff—Damages one farthing. (From the *Times* of 27th July, 1853.)

DEWHURST, THE PSEUDO-DOCTOR. "Professor Dewhurst", the well known begging letter impostor, is at present very active. The following is the copy of a letter which he sent to a lady whose name lately appeared as a contributor to the Medical Benevolent College:—

"10, Mitre Street, London.

"Dr. Dewhurst very humbly solicits Miss — to benevolently subscribe to his forthcoming work named in the prospectus, for which he will feel most grateful, as it will free him from the poignant distress he suffers through his frequent illness, and the want of constant literary, professional, and scholastic employment. The favour of an early reply with the enclosed is very humbly supplicated.

"Will Miss — condescend to inform him if there is in Clapham a Temperance Society, to whom he can offer his Lectures on Drunkenness?"

MEDICAL BENEVOLENT COLLEGE. At a meeting of the Council held on Tuesday last, Jas. Wm. Freshfield, Esq., M.P., in the chair, the Treasurer reported that on the late occasion of laying the foundation stone of the College, 315 ladies presented purses of five guineas, and that the collection altogether amounted to £3,400. Thanks having been voted to the Lord Bishop of Winchester for kindly officiating on the occasion, his Lordship was elected a Vice-President of the College, as was also Benjamin Eveleigh Winthrop, Esq., who presented on that day the munificent donation of 500 guineas. Dr. Colledge, of Cheltenham, was also elected a Vice-President. Thanks having been voted to the Rev. Wm. N. Harrison, the Vicar of Reigate, for having kindly advocated the cause of the institution on the 24th ult., that gentleman was constituted an honorary Life Governor of the College.

VACCINATION EXTENSION BILL.

[House of Commons, July 25th, 1853.]

The Bill passed through Committee without opposition. Various important amendments were adopted. The obligation to vaccinate from arm to arm, and from a healthy arm, is erased. The following clauses were introduced. They are clauses III, VI, X, of the Bill.

III. Upon the eighth day following the day on which any child has been vaccinated as aforesaid, the father or mother, or other person having the care, nurture, or custody of the said child, shall again take, or cause to be taken, the said child to the medical officer or practitioner by whom the operation was performed, in order that such medical officer or practitioner may ascertain by inspection the result of such operation.

VI. In all contracts to be hereafter made under the provisions of the first recited act, by any guardians or overseers of the poor with any medical officers or practitioners for the vaccination of the persons resident in their respective unions or parishes, the sums contracted to be paid shall not be less than the following rates; that is to say, for every person successfully vaccinated at the residence of such medical officer or practitioner, or within two miles therefrom by the nearest public road, a sum not less than one shilling and sixpence; and for every person successfully vaccinated at any place more than two miles distant from such residence, any sum not less than two shillings and sixpence.

X. A fee of threepence shall be paid to such registrar for each child vaccinated, in respect of which he shall have performed the duties required in this act; and he shall keep a book, to be provided as hereinafter directed, containing a minute of his having duly given such notice as hereinbefore directed; and the said fee shall be payable in the same manner as the fee now payable to such registrar for registering the birth of such child as aforesaid is paid.

THE CHARGE AGAINST A PHYSICIAN FOR RAPE. The charge against Dr. Banks, of Louth, Lincolnshire, for rape, was alluded to at p. 475 of our number for May 27th. For the honour of our body, and the reputation of the accused, we are glad to learn that the bill has been thrown out by the grand jury.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were Members of the Association.]

- ARTHUR, John, M.D., Deputy Inspector General of Army Hospitals, at 23, Church Road, De Beauvoir Square, Kingsland, London, aged 70, on July 18.
 FISHER, Nathaniel Briggs, Esq., Surgeon, at Bungay, Suffolk, aged 43, suddenly, on July 10.
 IZOD, Ibberson, Esq., Surgeon, at Newport, Isle of Wight, aged 25, on July 18.
 PHILLOTT, Arthur, Esq., Surgeon, of Wimpole Street, London, at Lee, Kent, lately.

ERRATUM.

In Mr. WEST's paper on "Obstetric Cases in Private Country Practice", published in last number, page 669, line 32, instead of "I have, therefore, classed them among the cases of the second and third positions respectively", read "I have classed them among the cases of the first and third positions respectively".

COMMUNICATIONS FOR THE EDITOR may be sent to the Editor's residence, Essex House, Putney, London: or to the office of the Journal. Letters requiring immediate attention and revised proofs ought invariably to be sent to Putney.

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XXXII.

LONDON: FRIDAY EVENING, AUGUST 12, 1853.

NEW SERIES.

THE RECENT DEPUTATION TO THE HOME SECRETARY FROM THE METROPOLITAN COUNTIES BRANCH ON THE VACCINATION BILL.

IN the *Medical Times and Gazette* of August 6th, we were astonished to find a leading article containing the official minute of an interview between the Home Secretary and Drs. Cormack, Fraser, and Semple, so interwoven with editorial remarks as to misrepresent the objects of the deputation, and to pervert its language. We trust that our contemporary will admit that he has been misled, when he peruses the following

STATEMENT BY THE DEPUTATION.

We, the undersigned, have read the following paragraph in a leading article of the *Medical Times* of Saturday last, August 6th:—

"We have our doubts whether the deputation acted wisely in making the question of professional remuneration a ground for postponing the Compulsion Clauses of the Bill."

We hereby declare, that in the interview with Lord Palmerston, the question of professional remuneration was never introduced.

We farther declare, that we did not urge any objection to the Compulsion Clauses of the Bill, and rested our petition for delay on the grounds stated in a minute, drawn up in the Home Office immediately after the interview with Lord Palmerston, and which was published in the *ASSOCIATION JOURNAL* of August 5th.

JOHN ROSE CORMACK, PATRICK FRASER, ROBERT H. SEMPLE.	}	The gentlemen who composed the deputation.
--	---	--

IS IT POSSIBLE TO REDEEM THE NEWSPAPER PRESS FROM ITS SERVITUDE TO FRAUD AND OBSCENITY?

THIS is the question which has been urgently repeated to us by more than a hundred correspondents. We cannot reply separately to each individual; and moreover, we cannot offer any other answer to it than that which we gave on the 22nd July, when we said:—

"If the attack on quackery in the fourth estate be wisely directed and well sustained, it cannot fail to be crowned with success. There are a few, we know, ready to maintain, that so essential is the money of the quacks to the very existence of most of the provincial newspapers, that such an attempt as that proposed can only be regarded as a well meant but hopeless crusade. A pretty extensive inquiry into the state of public feeling leads us to adopt a more cheering view of the case. We feel assured that there is an enormous power, slumbering at present, but quite ready, upon a proper signal being given, to march forward in united phalanx, and drive forth the quacks from their 'strongholds in the fourth estate', which at present seem almost impregnable."

In the article from which we have reprinted the above

paragraph, we spoke with well merited severity of the *North Wales Chronicle*, for admitting into its columns beastly advertisements side by side with religious and ecclesiastical controversies. We have now very sincere pleasure in stating that the editor, so far from attempting any defence of his conduct, admits its impropriety, and promises amendment. We cannot admit that the pecuniary difficulties of the paper afford any palliation of its servitude to sin; but as money bribes are the true explanations of the filthy state of the majority of the provincial newspapers, the editor cannot be blamed for alluding to their seductive power.

In a leading article of the last number of the *North Wales Chronicle*, we find the following passage.

"Our undoubted success, since we ventured upon the experiment of resuscitating an almost defunct journal, has long induced us to entertain a project which we have now determined to carry into execution, viz., the abolition from our columns of certain advertisements, which must be offensive to persons of correct taste, as well as injurious to public morals, and which will be done as soon as the termination of the present engagements permits. In discarding them, we sacrifice a large and regular amount of revenue, which, even in the improved circumstances of our paper, we can scarcely afford to do; but in this, as in all other matters, we look only to the general good, assured that our readers and supporters will not permit us to suffer for the attention which we pay to their wishes."

The *Edinburgh Christian Magazine* and the *North Wales Chronicle* have done well to take our censures in good part; and they deserve to have their amendment as widely published as their offenses. We trust, therefore, that those editors who are aiding our endeavours to reform the tone of the newspaper press may have the goodness to give the same publicity to these remarks, which they so kindly afforded to our former articles on "Quackery in the Fourth Estate".

For the zeal and energy of the *Reformer's Gazette* (a Glasgow newspaper), we are particularly grateful, because the great ability and honesty for which it is remarkable give to its advocacy of any cause much weight with the educated classes in Glasgow and the western counties of Scotland. We find, from the concurrent testimony of several members of the Association resident in Glasgow, that Mr. PETER MACKENZIE, the accomplished editor of the *Reformer's Gazette*, has long ago given to that paper a high status, from his telling exposures of medical quackery and its cognate villanies, as well as from his rigorous exclusion of all fraudulent and obscene advertisements. In these circumstances, the *Reformer's Gazette* mingles with its praises of our humble endeavours a gentle but just reprimand for our having neglected to acknowledge its earlier assaults upon that enemy, against which we have waged and begun a war—a war in which we shall neither ask nor give any quarter, and in which we shall accept of no offers of truce, except upon a guaranteed treaty of unconditional surrender.

In a leading article upon the *ASSOCIATION JOURNAL*, and its efforts to establish a "Society for the Suppression of

Fraudulent and Obscene Advertisements", the *Reformer's Gazette* of July 30th has the following observations:—

"The ASSOCIATION JOURNAL farther remarks:—'The *Scottish Guardian*, a Glasgow newspaper, excludes quack advertisements; and we believe there exists a small and honourable self denying minority who act in the same way.' Now, we have much pleasure in acknowledging this feature in the paper above mentioned; but when our London contemporary carries his inquiries a little farther, he will discover that there is another journal in Glasgow (with no pretensions to a semi-religious character) which not only steadily persists in excluding the quack advertisements, but which has been battling with the quacks themselves, and exposing the whole of the nefarious system in all its naked and hideous deformity for years.

"However, we are glad to hail the acquisition of the ASSOCIATION JOURNAL, with Dr. Cormack's powerful assistance, in this good cause. We like his style of writing on the subject; and, therefore, we have given a fair specimen of it in these columns. We beg to tell him that a pretty nest of venerable quacks will be found comfortably settled down, like so many grave doctors, in the Glasgow press, where they must now begin to imagine that they have the prescriptive right of tenancy claimed by other nuisances. We want a Hercules sadly, to muck (as we say in Scotland) this Augean stable of filth; and the arduous feat, if accomplished, will richly deserve to be rendered as famous in song as the celebrated 'Mucking of Geordie's byre', by our old friend, Sandie Rodger. It will be no easy operation, we are quite aware. The quacks and the quack-press will stick together like a conspiracy. We shall have homilies and sermons upon the subject. The whole herd of quacks will commence 'rowting and roaring' to some purpose, at the bare mention of 'mucking' their filthy byre. Rodger's vision will be realised:

But now they're far louder than ever,
They bellow wi' might and wi' main,
An' threaten to gore an' to skiver
The first that daur flash them again.
In droves, too, they gather thegither,
And closely united conspire,
To brak baith the stake an' the tether
Before that they get a clean byre.

However, we shall try and get them a clean byre. If the whole herd of Holloways, Du Barrys, Father Parrs, and Widow Welshes, should conspire together, we shall charge them all down the Gallowgate. We hope, by and by, with the aid of a well organised society, to see them fairly routed and rooted out. Everything depends on the honest and energetic cooperation of the public. Much depends also on *thoroughly* exposing the system. This must be the great aim of the society."

The *North British Advertiser* is another noble ally to whom the thanks of all good citizens are due. This paper, on the 6th of this month, announced that its publication of that day had a guaranteed circulation of 26,530; and we believe this statement to be strictly true. Its columns are entirely occupied with advertisements. The *North British Advertiser* never admits an advertisement bordering upon obscenity; and, during the many years in which we have weekly glanced at its columns, we have rarely detected announcements of deceiving character. When the magnitude of the enterprise in which the publishers of this paper are engaged, and the lateness of the hour and consequent bustle amid which numerous advertisements are received, are recollected, this is the very highest praise which we believe it possible for any newspaper to claim with justice.

A few days ago, a gentleman called upon Mr. JOHN GRAY, of the *North British Advertiser*, at his office in Edinburgh, and introduced himself as a member of the Society now forming for the suppression of fraudulent and obscene advertisements, who was anxious to benefit by his

experience. The facts unfolded by Mr. Gray are so interesting when viewed in connexion with the high character which his paper has uniformly maintained, that we append some of them for the instruction of our readers. Mr. Gray stated that, in the question of admission or exclusion, he followed no particular rule, but considered every case separately, and rejected those which seemed unsuitable, either with or without a reason. He gave many curious instances of his rejections, including one where some persons advertised for servants, offering wages so high as would have secured a great many hundred applications. Each answer was directed to be accompanied by a postage stamp: this, in connexion with the high wages offered, led to the suspicion that the advertisement was the trick of a swindler, and to its consequent rejection. Mercantile prospectuses, when manifestly on unsound principles, and not *bona fide*, Mr. Gray in like manner refuses to insert. The most serious difficulty experienced is with the decent advertisers of patent medicines, although his high charges generally prevent applications from such parties. Every allusion to generative debility, etc., etc., however correctly worded, he refuses to sanction; and he has repeatedly denied admission to advertisements of works on the rectum, bladder, urethra, piles, etc., in some cases even when he believed the authors to be respectable. When nothing in the language of an advertisement is likely to be distasteful to the general reader of delicate feeling, he feels himself in a position of some difficulty, and occasionally unable, as the servant of the public, to exclude that which he would rather avoid inserting. We suspect that this is one of the greatest difficulties with which the new society will have to contend; and we therefore set it forth as a point for the early and careful consideration of our friends, and as one upon which we shall often have occasion to touch.

We have been informed by a correspondent in York that one of the newspapers of that city—the *Yorkshire Gazette*—refuses to insert indecent advertisements. We have not seen this newspaper, but we shall be glad to receive some numbers of it, and subject them to the same tests by which we try newspapers professing similar purity.

From the above details, solid ground for encouragement may be derived; and did space permit, we might furnish much additional evidence of the same kind. Already, a noble army of allies is rallying round the standard which we have unfurled, and even, ere the battle has been set in array, detachments of the enemy show a disposition to surrender. This, however, far from engendering apathy or self-confidence, ought only to inspire us with more zeal and more determination.

Before another anniversary meeting of the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION, we doubt not that we, or our successors in office, shall be able to announce that the most noxious and the most beastly of the medical swindlers have been expelled from their principal strongholds in the fourth estate. In the meantime, the warfare must be active, and it must never slumber. Come forward then, fellow associates, and aid in this good cause. Let those who receive the circular which is about to be issued extensively by the provisional committee of the proposed society, reply to it early and fully. Let each individual act as if victory could not be achieved, unless he gave with his whole heart his individual exertions in behalf of the present movement.

ORIGINAL COMMUNICATIONS.

OBSTRUCTION OF THE LIVER.

By W. S. OKE, M.D., Senior Physician to the Royal South Hants Infirmary.

OBSTRUCTION in the parenchymatous or internal texture of the liver may be temporary or permanent; temporary, when caused by recent interstitial deposit of fibrinous lymph, or simple congestion of the capillary circulation in the organ; permanent, when it is the result of any organic change of its structure.

EXCITING CAUSES. These will be found in inflammation, intermittent or remittent fever, long residence in hot climates, excessive drinking, etc.

SYMPTOMS. When obstruction has taken place in the internal organization of the liver, the following symptoms will usually mark the progress of the disease: a sense of fulness and tightness across the epigastric region, pain and tenderness of the right hypochondrium, jaundice, embarrassed respiration, intestinal or gastric hæmorrhage, anasarcaous swelling of the inferior extremities, dropsy of the belly, and lesion of the heart.

PATHOLOGY. The above results may be explained in the following manner. The whole of the portal circulation being formed by veins derived from the stomach, intestines, spleen, pancreas, and omenta, the blood which fills them must necessarily flow from the arteries supplying those viscera, namely, the celiac (excepting the hepatic branch) and the superior and inferior mesenterics. When, therefore, the vena porta hepatica becomes obstructed in its capillary system, the immediate effect must be a congested condition of the vessels of the viscera just mentioned, unless relieved by gastric or intestinal hæmorrhage. If the congestion be not so relieved, and the obstruction continue, the celiac and mesenteric arteries will be obstructed also, and gradually disallow the normal quantity of blood to pass through their channels. The abdominal aorta will then have to inject more blood through the iliac arteries into the inferior extremities than the returning vessels can carry back; and, consequently, infiltration through their capillaries into the cellular tissue must take place, and cause anasarcaous swelling. If the obstruction be long continued, the same thing will occur in the abdominal circulation, and peritoneal dropsy will follow: and further, if the obstruction be permanent, the heart will be at length involved. By its constant efforts to pump the blood through the congested and obstructed vessels, the left ventricle will become hypertrophied and dilated, and its valvular apparatus diseased, as evidenced either by a bellows, sawing, or rasping sound. Moreover, the mischief might not end even at this point; for, as the vascular system becomes more and more obstructed, the respiratory and cerebral organs also will be implicated, and in danger of infiltration or extravasation from their congested vessels.

DIAGNOSIS. When the obstruction is incipient, that is, before any infiltration has taken place, it may be diagnosed by a feeling of embarrassment in the breathing, a dry cough, pain and tenderness in the right hypochondrium, and a jaundiced aspect; and when it is of longer standing, in by far the majority of cases, the liver itself is more or less enlarged, which alone will suffice. Should the enlargement be concealed by dropsy of the belly, the indurated surface of the liver may often be easily detected by deep pressure of the fingers, suddenly made below the margin of the ribs. Enlarged liver cannot well be confounded in this stage with any other cause of obstruction; not with enlargement of the spleen, because here all the symptoms arise in the left hypochondrium; nor with renal disease, because, in the latter case, the microscope, the urinometer, and chemical tests, will infallibly demonstrate a morbid condition of the kidney. The disease which may more probably be mistaken for disease of the liver is a large tumour occupying the epigastric region; but, even in such a case, the presence or

absence of the acute margin of the liver will decide the question one way or the other. The following is a case of this kind, and is quoted from my *Practical Examinations*, p. 68.

CASE. J. D., aged 28, a blacksmith, placed himself under my care in the Southampton Dispensary, on account of an enormous tumour upon the epigastric region, which had been gradually increasing during eight months, and which he thought arose, in the first place, from a strain in lifting a heavy piece of timber. It appeared to be sarcomatous, and extended longitudinally from the ensiform cartilage to the navel, and transversely from the anterior margin of the ribs on one side to that of the other: indeed, it could be traced beneath the ribs on the right side. It was of a flattened shape, and, as well as I could judge, about three inches in thickness. Its texture was generally firm, except at one point on the left side, where a fluctuation could be distinctly felt, occupying a cavity about the size of a hen's egg. He had been first under the care of a gentleman in the neighbourhood where he lived, and subsequently under a physician in the county hospital, by both of whom many judicious means had been employed, but without success; and I confess, from the opinion I had formed of the character of the tumour, that I did not expect he would have received any benefit from me, fearing that the disease arose from an enlargement of the liver.

I ordered him the extract of sarsaparilla, with an alterative dose of the oxymercurate of mercury, three times a day; and local friction with tartarised antimony ointment; but, finding that the tumour did not subside under these means, I exchanged the antimonial ointment for that of the iodide of potassium, by which the tumour was eventually absorbed.

When one only of the inferior extremities is oedematous, the swelling can hardly be due to any hepatic obstruction; it must rather be sought for in some local pressure upon one of the common iliac veins before they form the vena cava abdominalis. Not long ago, I met with an interesting case of this kind, which was at first very obscure, and was attributed to hepatic causes.

CASE. Miss W., aged 37, of short stature and venous aspect, having been several times attacked with pain and constipation of the bowels, became affected with severe neuralgia of the branches of the right crural nerve, at the upper, outer, and front part of the thigh. The pain returned in paroxysms of great suffering, and was aggravated by lying in the horizontal position. The utmost attention was paid to ascertain the cause of her sufferings, and every possible remedy, both internal and external, was tried for her relief; but, in spite of all, the neuralgic pain returned with undiminished severity at irregular intervals. She became lame, could not bear the weight of the body upon the right foot, nor make the slightest effort with the rectus femoris muscle without intense agony. The limb, as high as the knee, was oedematous, assumed a dark blue aspect, and lost much of its warmth. The inguinal and iliac regions were repeatedly examined; but nothing appreciable could be detected to account for the obstruction to the circulation. At length, by a deeper manipulation, a flattened tumour was felt behind the abdominal muscles, lying upon the right iliac fossa, in the track of the external iliac vein, which at once explained the whole of the matter.

Before quitting this part of my subject, I would remark, that a bilious aspect must not *always* be expected in the advanced stage of hepatic obstruction. In some cases, the aspect is venous or pallid, without the admixture of any bilious tint whatever; and that where an immense enlargement of the liver is at once evident. I remember an instance of this kind in an elderly lady, who had for very many years an enlargement of this organ, the acute margin of which could be traced considerably below the umbilicus. Her lower extremities were often oedematous; the heart's action was interrupted; the respiration sometimes embarrassed; she was attenuated, pale, and liable to profuse hæmorrhage from the nose: in short, there could be no question as to the character of the disease; and yet she had never exhibited any appearance of jaundice to the day of

her death. Saunders, in a note to his valuable work on diseases of the liver, states that, "in many cases, as has been already observed, the liver is so far diseased, that it does not even secrete bile, and a pallid and unhealthy aspect takes place."

TREATMENT. If it be correctly stated at the commencement of this paper, that hepatic obstruction might be caused either by the recent deposit of fibrinous lymph, by congestion of the portal capillaries, or by organic lesions, the curative indications will be sufficiently plain, and, in the two first, will often be successfully fulfilled by the efficacy of medicine. If, then, the symptoms of obstruction have followed closely upon an inflamed condition of the organ, interstitial fibrinous deposit is probably the cause, and will best be treated with mercury combined with diuretics.

Should there be any remaining tenderness of the right hypochondrium, with darting pain and an acceleration of the pulse, local bleeding and external irritation may be added. When there is no evidence of antecedent inflammation, and the anasarca, embarrassed respiration, etc., have succeeded to an intermittent or asthenic fever, and the symptoms are associated with those of great debility, with a weak irregular pulse, and a venous and bilious aspect, congestion of the portal capillaries is to be suspected, and the case must be treated with calomel combined with tonics, diuretics, and a generous diet.

CASE. J. C., a labourer, aged 50, of a bilious and venous aspect, had been suffering from tertian ague many weeks. As the paroxysms subsided, he felt pain and tenderness of the epigastric region, which was prominent; his stomach was uneasy after meals; his breathing was extremely embarrassed; and he could not lie down. The abdomen was swollen, and his lower extremities were greatly enlarged with anasarcaous infiltration. The secretion of the urine was irregular, sometimes scanty and high coloured, and sometimes more copious. The tongue was furred; the pulse intermittent; and he was so weak and oppressed, that he could scarcely bear the journey to my house.

As it appeared to me that the symptoms of obstruction in this case were caused by a congestion of the hepatic capillaries, weakened by the preceding intermittent, I ordered disulphate of quinine with calomel and squills, as in the last prescription, three times a day. The result exceeded my most sanguine expectations. The bowels were gently acted upon; the renal function speedily restored; the anasarcaous swelling gradually subsided; and, in a few weeks, he was able to walk a distance of three miles, to report himself cured.

But, when the cause of obstruction has advanced to a morbid change in the structure of the liver, the disease becomes permanent and incurable. It matters not whether the organ be enormously hypertrophied, cirrhotised by hard drinking, or atrophied and shrunk up into a dark coloured tuberculated mass: the result will be eventually fatal. It is true, that the dropsical infiltrations may sometimes be removed, either by the renal secretion being artificially increased, by the escape of the serum through cutaneous outbreaks between the knee and ankle, or by scarifications, so as often to delude the patient with a hope of recovery; but, in a short time, the oedema, with all its distressing associations, is sure to return again and again, till the constitution is exhausted, and succumbs to the disease.

The following is a case of obstructed liver from organic lesion, showing its fatal progress.

CASE. Geo. G., aged 35, tall and well built, went to the coast of Africa, as a shipwright, in 1846, in H.M. brig *Wasp*. He had not been long in this service before he was shot through the left side of the thorax by a musket ball, in an attack upon a slaver. The ball entered between the third and fourth ribs, and was extracted from beneath the integuments at the edge of the base of the scapula. He completely recovered from the wound. After about two years' residence on this station, from the heat of the climate and excessive drinking, his liver became involved. He complained of acute pain through the right hypochondrium, which was attended with jaundice, white stools, and bilious urine. These symptoms were followed by fulness of the abdomen, anasarca of the inferior extremities, and soon afterwards by cough, shortness of breathing, and undue action of the heart. This state of things continuing more or less for a considerable time, he was invalided home.

When I first saw him, about three months ago, his breathing was exceedingly short; he was unable to observe the horizontal posture; his inferior extremities were enormously swollen with anasarca; his abdomen was ascitic, and the skin of a venous hue. The whole of the right side of the belly, from the inferior margin of the ribs to the crest of the ilium, was prominent, dull under percussion, and exhibited an immense enlargement of the liver. The heart was hypertrophied and dilated, and imparted a distinct *bruit de râpe*, from probably a morbid condition of the mitral or aortic valves. From this time, although he was, as a forlorn hope, speedily brought under the action of mercury, he grew rapidly worse. The jaundice returned, accompanied by intestinal hæmorrhage; and he is now sinking under the fatal progress of the disease.

I have another case of enlarged liver in our infirmary, in which there is a distinct sawing sound in the mitral valves; indeed, I rarely meet with obstructed liver, occasioned by organic disease, that is not associated with disease of the heart also.

When the abdomen is much distended with serous fluid, it is seldom that absorption can be effected by the aid of medicine; and therefore, as the abdominal and thoracic functions become interrupted, it will be necessary to evacuate it by the trocar as often as the symptoms may require. If the external opening can be made fistulous, so much the better. I saw one instance of immense distention, in a man over the middle age, with bilious aspect, in which this was effected, and he recovered; but in this case there could not have been any organic lesion, or the relief would have been only temporary.

Hæmorrhage from the portal veins is another effect of obstructed liver. It may be both vomited from the stomach and discharged from the bowels. It is of course venous, comes away coagulated, and generally in immense quantities, leaving the patient exhausted and bloodless.

The treatment of this symptom requires caution. The indications clearly are to remove, if possible, the capillary obstruction in the liver, and to prevent a return of the portal congestion. These, in my own practice, have been best fulfilled by the following:—

R. Pilulæ hydrargyri,
Extracti copaibæ, aa gr. iv. Misce.
Divide in pilulas duas omni nocte sumendas.
R. Magnesiæ sulphatis ʒss.
Spiritus ætheris nitrici 3ij.
Syrupi aurantii ʒss.
Tincturæ hyoscyami ℥xx.
Infusi rosæ compos. ad ʒvi. Misce.
Capiat quartam partem bis terve die.

Sometimes the bleeding takes place from the hæmorrhoidal veins, which are also a part of the portal system. So long as it appears to be beneficial in relieving the congested condition of that system, and, in fact, the obstruction of the liver itself, without too much debilitating the constitution, it ought never to be stopped, either by me-

dicine or any surgical operation; but when the loss is a daily occurrence with every motion, and so profuse as to produce all the distressing symptoms of anæmia, extreme pallor, shortness of breathing upon the slightest exertion, palpitation, beating of the temporal arteries, indicating great debility, it becomes absolutely necessary to stop the bleeding, lest the constitution should sink from sheer exhaustion; for we must remember that this is not a mere case of occasional piles from local causes, such as a costive habit of body, the gravid uterus, etc., where there is no hepatic obstruction, but a bleeding from an extensive system of obstructed veins without valves, and therefore more apt to bleed profusely.

The remedy which will be found most efficacious in restraining such hæmorrhage, is the purified oil of turpentine, with the tincture of kino, as prescribed in the following formula:—

R Olei terebinthinæ pur. 3ss.
Tincture kino,
Syrupi zingiberis, aa 3j.
Aque cinnamomi,
Aque mollis, aa 3ij.
Misturæ sacchar. q. s. ad bene miscendum.
Fiat haustus bis terve die sumendus.

It is important that the oil should be first carefully rubbed down with the mucilage, and the other ingredients gradually added, in order that the draught may be well mixed; otherwise it may be rejected.

I will now adduce a few cases, to show the efficacy of this treatment.

CASE I. A tradesman, aged 45, the father of a large family, had been for a considerable time subject to daily hæmorrhage from the veins of the rectum. He had lost so much blood with every stool, as to become blanched and exhausted. Several medical men had been consulted, who endeavoured to restrain the bleeding by a variety of remedies, both internal and external, but without success; and the patient had prepared himself for a fatal issue. Being requested to visit him at this time, I placed him at once under the above treatment. The effect was really marvellous. The bleeding was almost immediately controlled; and, what greatly surprised me, the stools, which had been of an ash colour,—and they are always of a light colour in these cases,—assumed a healthy and well digested appearance. It is, therefore, probable that the turpentine not only acted as a styptic, but also as a deobstruent in removing, in some way or other, the hepatic obstruction. Be this as it may, the bleeding never returned; the patient gradually regained his good looks, and has for many years enjoyed excellent health.

CASE II. A lady, aged 47, unmarried, of a bilious aspect, and regular in her menstruation, had been for some time disordered in the hepatic function, and subject to severe facial neuralgia. She was, at the same time, in the habit of losing large quantities of blood by stool. After a while, the bleeding ceased spontaneously; but her general health did not satisfactorily improve. Shortly afterwards the hæmorrhage returned, and continued daily for two months; when she became so bloodless and debilitated, as to occasion great anxiety and alarm to her friends. I went to town to see her, and immediately recommended the turpentine in the above formula. In a week the bleeding was controlled, and the medicine was left off. It returned, however, as profusely as before, and the remedy was resumed three times a day for another week; after which it was again and completely successful. She has been in good health for the last two years.

CASE III. Mrs. C., aged 39, married, but without any family, came to consult me, in February 1852, for bleeding from the hæmorrhoidal vessels. She informed me that she had lost a large quantity of blood with every stool, but at no other time, for the last eight months. Her aspect was most unfavourable. She was pale as death, and was constantly drowsy. Her pulse was feeble and rapid, her tongue colourless and cold, her feet cedematous, her respiration hurried, and her strength so exhausted that she was scarcely

able to walk across the room; in short, she appeared to be in a hopeless stage of anæmia.

In this case, as in the two former, the same treatment was equally successful. At her next visit, she told me that the hæmorrhage had ceased on the third day after she had commenced the medicine, and reported herself much better. From this time her health steadily improved, without any return of the bleeding; and her strength was restored under the use of dilute sulphuric acid and decoction of bark, with gentle aperients.

Turpentine, in the above formula, has seldom failed in my own practice to ensure the purpose of a styptic in this kind of hæmorrhage. Whether it acts as a deobstruent also in removing the obstruction of the portal capillaries, I have not sufficient evidence to decide; though, from its subtle qualities entering the vascular system so rapidly, such a result is not improbable. It certainly appeared so to act in the first case. As a styptic for internal passive hæmorrhage it stands unrivalled.

The bowels are to be regulated by such aperients as will gently act upon the liver, without irritating the rectum.

R Pil. hydrargy.,
Extracti jalapæ (vel extr. rhei),
Extracti copaiabæ, sing. ʒj. Misce.

Divide in pilulas xij; è quibus capiat duas horâ somni pro re nata.

Should the bleeding recur from a hæmorrhagic idiosyncrasy, an injection of cold water should be employed every morning; which will not only evacuate the bowels, but give tone to the veins of the rectum.

Southampton, July 13th, 1853.

CLINICAL ILLUSTRATIONS OF SOME DISEASES OF THE ŒSOPHAGUS.

By C. E. REEVES, B.A., M.D.

SPASMODIC STRICTURE.

THE position of the inferior constrictor of the pharynx, at the point of junction of the two portions of the gullet, renders it, like all constrictors, extremely susceptible to spasmodic contraction, whether arising from direct or from indirect irritation. Contraction of a spasmodic character is rarely met with in any other part of the canal; yet Courant* mentions an instance where it existed at both extremities at the same time, the alimentary ball being conveyed from one end of the canal to the other, and then expelled with violence or driven into the stomach. In Percival's† case it existed at the lower extremity; and in the one published by Dumas‡ at the point where the œsophagus passed through the diaphragm.

PATHOLOGY. It is rare to find any morbid change in the œsophagus, even when spasmodic stricture has existed for a considerable length of time. Portal, Monroe, Howship, and others, report cases of this kind. "It will," says Abernethy,§ "be readily allowed that spasmodic stricture, when long continued, may cause a thickening in the affected part of the tube"; and Baillie|| states that thickening of the canal may be sometimes met with at the *post mortem* examination. But the reverse does occur, thickening often giving rise to spasmodic contraction.

CASE. F., aged 44, single, just at the change of life, after exposure to wet and cold, experienced some slight dryness in the throat with a sense of undefined uneasiness. She found on eating fast or swallowing a large mouthful, if not well masticated, that the food was apt to become arrested in the throat, requiring several gulps to get it to descend, yet it was not sufficient to cause any uneasiness, or require fluid

|| Morbid Anatomy.

to assist it. The illness and subsequent death of her father, about nine months from the commencement of the affection of the throat, affected her general health materially. She became dull and desponding. While in this state, she was exposed to cold and wet, which brought on an attack of spasmodic stricture. It lasted two days; it then subsided under treatment, leaving the difficulty of swallowing much in the same state as before the attack.

In the following case, spasmodic stricture had existed three years, yet no thickening was found after death.

CASE. F., aged 52, tall and thin, with dark complexion and grey hair, since the disappearance of the menstrual discharge four years previously, had become highly nervous and irritable, and for the last three years subject to attacks of difficulty of breathing and also of swallowing, generally occurring after dinner, but also liable to occur during any other meal, particularly if it were of a substantial character, or if more were taken than enough to stay the appetite. Attacks were excited by drinking cold fluids, when heated by exercise or sitting in a close room. During the last two years of life she became subject to frequent attacks of hæmorrhage from the nose. She died rather suddenly from apoplexy.

The mucous membrane of the œsophagus seemed rather more vascular than usual; the mucous follicles were more developed, but there was no contraction or thickening of the canal. The brain contained in its right hemisphere a large clot of blood; the right and left lateral ventricles also contained blood; and the septum lucidum was destroyed. The vessels of the membrane covering the medulla oblongata seemed rather larger than usual, and the substance of the medulla itself more vascular, but the eighth pair of nerves seemed quite normal. The walls of the left ventricle of the heart were rather thick, and the auricular ventricular orifice was somewhat contracted. The liver was large and slightly livid, but all the other viscera were normal. The uterus was very small, and the ovaries were much contracted.

Hysteria had never existed in either case.

CAUSES. These may be considered under two heads: direct and indirect.

1. *Direct.* Under this head, affections of the larynx, trachea, pharynx, and œsophagus, and foreign bodies, may be placed.

2. *Indirect.* This head includes affections of the stomach, liver, and diaphragm, uterus, gout, and suppression of cutaneous eruptions.

In addition to the above, a third cause exists, namely, affections of the brain and upper part of the spinal cord.

1. **AFFECTIONS OF THE LARYNX AND TRACHEA.** Mr. Shaw* has published the following case. "I was", he says, "requested to make the *post mortem* examination of a person about whom some doubt as to the nature of the disease existed during life. He had first suffered from pain in the throat, with expectoration of blood, which continued for some time, and was then followed by purulent matter and great difficulty of swallowing; bougies were repeatedly introduced, under the idea that stricture of the œsophagus existed. The opinion of another physician having been sought, he stated that the spasmodic stricture depended on disease of the larynx. He gradually sank, presenting, however, at times marked symptoms of stricture. The back part of the tongue, epiglottis, tonsils, and sac of the larynx were found eroded, the chordæ vocales thickened, and an ulcer existed in the upper part of the pharynx, but the œsophagus was quite healthy. The lungs contained a number of miliary tubercles."

"I was", says Howship,† "with Dr. Hooper, consulted on the 4th Dec., 1823, by a middle aged gentleman. He was, after exposure to cold and damp, first affected with soreness about the throat attended with some degree of fever, which left him without having recourse to medical treatment. Soon after, he began to suffer from soreness in the course of the trachea, with constant spitting of frothy mucus. In addition to these symptoms, a difficulty in swallowing came

on, gradually increasing in severity. The throat, on examination, seemed free from disease; but on depressing the tongue, severe irritation was excited, which was followed by the rejection of a large quantity of glairy mucus. The pulse was 90, rather hard, the skin hot, and the tongue white. A bougie was passed several times with great relief to the difficulty of swallowing. Dec. 22nd. An attack of severe pain in the side rendered antiphlogistic treatment necessary. The passing of the bougie was continued: in doing so, it was necessary to press lightly for the space of a minute on the obstruction at the lower part of the pharynx, which then gave way. He could now swallow with comparative ease, the sense of soreness in the larynx continuing and the expectoration was for a time much diminished under treatment, but early in January hectic symptoms set in, and he sank on the 18th.

"The epiglottis was found nearly destroyed; the larynx was ulcerated; but no trace of disease existed in the œsophagus. The intestines were ulcerated."

He mentions a case of spasmodic stricture occurring in a female in the last stage of consumption. Symptoms of irritation in the larynx and trachea had been present for some time. A bougie was passed: it met with an obstruction in the lower part of the pharynx, which was surmounted by slight pressure. She died eighteen days after.

The œsophagus was found constricted to half its diameter, for the extent of half an inch, from the effusion of lymph; the trachea was highly vascular, and covered with purulent mucus; the larynx was healthy; the lungs were diseased.

Mayo (*Outlines of Pathology*) mentions a case of ulceration of the larynx in a young man who suffered from great difficulty in swallowing. A bougie met with some resistance in the upper part of the œsophagus.

AFFECTIONS OF THE PHARYNX. CASE. ULCERATION OF THE POSTERIOR PART OF THE PHARYNX. A young man, of a scrofulous irritable habit, some time after having been cured of primary syphilis, became affected with superficial ulceration of the posterior part of the pharynx. A person to whom he applied, considering it to be secondary syphilis, advised him to undergo a second course of mercurial treatment. At the end of a week, from exposure to cold and wet, joined to habits of dissipation, he suffered from huskiness of the throat, and some slight thirst the next day. In the evening, the symptoms in the throat rather increased; and after tossing about some hours he got to sleep, but was suddenly awakened by a sensation of choking. He attempted to drink a glass of cold water, but the fluid excited so much spasm on entering the throat, that it was returned. He was seen three hours afterwards, suffering severely from thirst, which he was unable to allay. On examining the throat, there was observed some slight swelling of an erysipeloid character. The free application of a solution of nitrate of silver, and an anodyne clyster, soon enabled him to swallow a little warm fluid with ease.

Paletta* mentions the following case of stricture from secondary ulceration of the pharynx. A nervous man contracted syphilis, which was cured by a mercurial preparation. In the autumn of the same year, he suffered from an attack of intermittent fever, which was cured by bark. Immediately afterwards, an eruption appeared on the chest: at the same time, difficulty in swallowing came on, and a sense of soreness at one side of the pharynx. At the end of a month, the dysphagia had much increased, with a copious expectoration of viscid mucus, occasionally mixed with blood. Nothing could be seen on examining the throat; but, by means of the finger, an ulcer was easily felt. He was cured by the exhibition of mercury.

Morgagni† relates an instance of a female suffering from ulceration of the fauces, who had dysphagia.

Blassius‡ gives the following case of ulceration of the lower part of the pharynx:—

* Exercitationes Pathologicae. Mediolani, 1690.

† De Caus. et Sed. Morb. Epist. xxviii. Art. ii.

‡ Obs. Anat. Chirurgo-Medicæ, 1781. Dec. 4, Obs. 3. *Dysphagia* *causa* *ulcerationis* *pharyngis* *inferioris* *partis*.

* London Medical and Physical Journal, 1822.

† Practical Observations on Indigestion.

A female, aged 22, who menstruated irregularly, and was frequently the subject of coryza, became in 1730, after having had several attacks of ophthalmia, the subject of inflammation of the right tonsil and uvula, with swelling of the parotid gland of the same side. Soon afterwards, difficulty in swallowing set in. On exploring the pharynx with the finger, an ulcer was felt. This had evidently given rise to spasmodic contraction, on food and drink coming in contact with it. Under the use of astringent gargles and delayants, she was cured in fourteen days.

Baldinger* has recorded the following interesting case:— In 1785, a sensation of constriction in the pharynx was first experienced, which lasted four hours. The succeeding six weeks, it occasionally occurred, but very slightly. At the end of this period, it became more frequent and severe, attended with a sense of soreness, confined to one spot on the left side of the pharynx, not larger than a linseed: swallowing sour or sharp substances increased the sensation of soreness to one of smarting: the food and saliva were swallowed with great difficulty. These attacks came on only in the evening, continued during the greater part of the night, and disappeared towards morning. Blisters and change of diet were tried in vain; camphor gave considerable relief; but, at the expiration of six or eight weeks, the symptoms returned, but the exhibition of camphor caused them again to disappear in the course of a few days. In the winter, the disease again returned with greater severity, and was attended with difficulty of breathing, to which the patient was subject during the winter months. In June 1786, an eruption appeared on the extremities, which was followed on drying up by a severe cough (evidently depending on the affection of the pharynx), lasting about a quarter of an hour, and attended with retching. Nothing, however, was brought up but some slimy mucus. The attacks continued, with more or less severity, being sometimes absent for some time, and then returning, continuing for a longer or shorter period. In the winter of 1786, the sensation of soreness changed from the left to the right side of the pharynx, but not so severe as to attract much attention, yet it was attended with a strong afflux of saliva, and difficulty in swallowing. As before, it occurred at longer or shorter intervals, and was more or less severe. One of these attacks was attended with heat of the skin, followed by great difficulty in bending back the head, and turning it round. The affection lasted until 1787, when, under treatment and careful diet, the attacks were much mitigated.

CASE. AFFECTIONS OF THE ŒSOPHAGUS: SPASMODIC STRICTURE DEPENDING ON INFLAMMATION OF THE LOWER PART OF THE ŒSOPHAGUS.† F., aged 52, when forty-two years of age, experienced attacks of pyrosis: her health was otherwise good. One year afterwards, she was confined of a healthy full-grown child, which she nursed for a year. Then some disorder of the stomach set in, attended with nausea, constant hawking up of a thick glairy fluid, with regurgitation of food, and often of liquids. She ceased to nurse, yet the affection gained ground. Her chief complaint was of weight at the pit of the stomach, with some obstruction to the food passing through the cardiac orifice; but, when once this difficulty was got over, digestion went on well. At times, she suffered from spasms of the upper part of the œsophagus. Various remedies were had recourse to, but leeches and sea-bathing seemed alone to give her any relief. In August 1843, she accidentally swallowed a prune-stone, and the difficulty of deglutition, which had been for some time better from the treatment adopted, returned. Nothing could be made to enter the stomach. A bougie was introduced with some slight difficulty, yet no foreign body could be detected. Leeches, baths, and other remedies, were employed in vain. The spasm was at times referred to the upper, at others to the lower part of the canal. Every fifteen days, she suffered from attacks like ague. Her

breath had a highly acid odour, which pervaded the whole room. She at last sank on December 24th, having been nourished for some time by means of nutritive clysters.

A narrowing was found extending upwards from the cardia more than two and a half inches. The little finger could with difficulty be made to pass; the walls were not thickened; the œsophagus contained a prune-stone; two gangrenous patches existed just above the contraction, with some red points in others. The rest of the canal and the other viscera were healthy.

CASE. CHRONIC INFLAMMATION GIVING RISE TO OCCASIONAL ATTACKS OF SPASMODIC STRICTURE.* M., aged 50, nervous, yet of strong constitution, had been subject, for the last ten years, to occasional attacks of spasmodic stricture. On the 20th of November, 1836, he had an attack. This passed off, and he was in his usual excellent health. In the evening, he made a supper on apples, and afterwards attempted to swallow a potato, which became arrested in the throat, and was got rid of by vomiting. The irritation of the potato brought on a return of the stricture in all its severity. After two days' suffering, medical assistance was sought. He complained of a pain in the throat, opposite the thyroid cartilage; and there the obstruction to swallowing existed. The thirst was intense; efforts to swallow a little fluid gave rise to a peculiar gurgling sound, and, if long continued, to convulsive contractions of the muscles of the face, and pain between the shoulders, and discharge of thick cream-like mucus. Blisters were applied to the nape of the neck, leeches to the throat, and belladonna clysters were thrown up.

November 24th. He was no better. A dose of morphia gave immediate relief; and he was soon enabled to swallow fluids with the greatest ease.

INFLAMMATION OF A CHRONIC CHARACTER GIVING RISE TO SPASMS, AND FOLLOWED BY AN ATTACK OF ACUTE INFLAMMATION.† F., a middle aged female, had suffered during the last few days from attacks of difficult swallowing, particularly of fluids. The swallowing of a little cold water relieved her. A silver ball, half an inch in diameter, was passed to the bottom of the pharynx, where some slight obstacle to its passage was met with. The affection afterwards took on an inflammatory type, and was treated with leeches, blisters, etc.

Abercrombie‡ mentions a case somewhat analogous. A. F., forty years of age, had suffered for more than a year from symptoms of spasm of an irritable character. Bougies had been passed, and various remedies employed, in vain. By mere chance, he ordered a silver ball, attached to a piece of wire, to be passed: this, after four or five introductions, quite removed the affection.

Mr. Lawrence, in his Lectures (*Lancet*, 1829-30), mentions the case of a young lady, who, from some affection of the throat, could not take food without exciting spasmodic constriction.

Thillnéus§ mentions a case where a man was unable to swallow any solid or fluid, even at the temperature of the atmosphere, without giving rise to spasm; yet, when hot, he could swallow them with the greatest ease.

Courant|| mentions a like instance. In the case published by Percival in the *Transactions of the College of Physicians*, cold fluids met with greater obstruction than warm. The reverse is occasionally met with, as in the second case quoted above, and in other observations mentioned by different writers.

CASE. SPASMODIC STRICTURE OF TEN WEEKS' DURATION, EXCITED BY AN EMETIC.¶ A robust female drank, when heated from dancing, a large quantity of cold water, which

* Dr. Olaszewski, in Caspar's *Wochenschrift*, 1837.

† Howship, *Pract. Observations on Indigestion*.

‡ Abercrombie, on *Diseases of the Stomach*, etc. This case also somewhat resembles the one published by Sir E. Home, in his work on *Stricture*. A female, after much retching from a sea passage, suffered from difficulty in swallowing, which increased in severity. A bougie was passed with some difficulty, but the next day she could swallow with ease.

§ Jour. de Méd. Chir. et Phar., 1791, p. 280.

† LAMOTHE, Jour. de Méd. de Bordeaux, 1844.

produced great uneasiness and distension of the stomach. An emetic was exhibited, which acted about twenty times, and produced also several evacuations from the bowels. Spasmodic contraction of the œsophagus set in, and the menstrual discharge, which had just appeared, was suppressed. Five days passed without anything entering the stomach; the patient was greatly exhausted from want of food, and suffered intensely from thirst. An elastic tube was now introduced into the stomach with some difficulty, and through this food was administered. At the expiration of ten weeks, the menstrual discharge reappeared, and the spasm subsided. Carron* mentions an instance where a strong emetic excited spasmodic stricture of the œsophagus.

Harrington Square, London, July 1853.

[To be continued.]

THREE CASES OF POST-PARTUM HÆMORRHAGE.

By FREDERICK JAMES BROWN, M.D.

CASE I. PLACENTA PRÆVIA: DELIVERY: HÆMORRHAGE ON THE NINTH DAY, AND DEATH. EXAMINATION OF THE BODY. Mrs. Gadfield, aged 37, residing at Strood, the wife of the mate of a coal vessel, sent for Dr. John Dan Brown, on the morning of Saturday, 30th April, 1853. She was at the full term of her sixth pregnancy. She had been attended previously by Dr. J. D. Brown, when she had favourable labours.

She stated that she had a "show" three weeks ago, succeeded by another in a short time; and that she had a "show" on the nights of Thursday and Friday, the 28th and 29th April. Through Friday night and the early morning of Saturday, she lost half a potful of blood. She had had very slight pains. On examination, the os uteri was found thin and rigid; it was equal in size to a shilling. The placenta was felt over all the os uteri that was open. There was bulkiness of the posterior part of the os and cervix uteri. The presentation was cranial. There were no pains, and no hæmorrhage. The vagina was plugged, and rest in bed enjoined. At 9 p.m., hæmorrhage recommenced, the blood escaping by the side of the plug. Slight pains had occurred from 7 p.m. On withdrawing the plug, there were gushes of blood, greatly increased by each pain. The patient's system was suffering from loss of blood. The pulse was small and weak, not rapid. The os uteri continued rigid. The plug was reintroduced, and the assistance of an able and experienced practitioner was sought. The hæmorrhage by the side of the plug, during a pain, was now but slight. At twenty-five minutes to 11 p.m., the os uteri being thin, somewhat rigid, and nearly equal to a crown in size, Mr. Ely of Chatham commenced dilatation. By 11 o'clock, dilatation had been carefully effected, the child turned, and the right foot brought down. The child was delivered by pains and the assistance of the operator, in fifteen minutes after the version. The placenta was found to be detached, and was removed from the vagina in five minutes.

During the operation, the placenta was ascertained to be attached over the posterior part of the os uteri, thus permitting the operator to reach the membranes anteriorly, and to evacuate the liquor amnii in carrying up the hand. The uterus contracted well after the birth of the child; and the pulse became augmented in strength and volume. There was no hæmorrhage.

The child, which was a female, was dead. No pulsation was felt in the funis during the operation. Its death appeared to be quite recent, not exceeding a few hours. The patient fell asleep, and was not removed to a dry part of the bed until after two hours and a half.

May 1st. The patient had not slept during the night. She had pain in the abdomen, in the left iliac region. The pulse was 108. Calomel and opium were given; and four leeches were applied to the abdomen.

May 2nd. She slept in the night. There was pain along the left side of the uterus, and hardness, forming a ridge in the abdomen. The lochia were scanty; the pulse was 108, moderately full; the tongue dry. The calomel and opium were continued.

May 3rd. She slept in the night. The bowels were much acted on by the mercury. No pain, swelling, or hardness by the side of the uterus remained. The whole abdomen was swelled in the morning; but the meteorism disappeared in the afternoon. Pulse 112, large and firm; tongue clean. The calomel and opium were omitted.

May 4th. She slept during part of the night. The diarrhoea had ceased; the bowels had been twice open. Pulse 108; tongue clean. Pain in the umbilical region came on in the afternoon. Four leeches were applied; and some doses of hydrargyrum cum creta and Dover's powder were ordered.

May 5th (*vespere*). The pulse was 116 at six o'clock; 104 at nine o'clock. The patient complained of uneasiness and fulness of the abdomen. A blister was applied to the middle portion of the abdomen; and Dover's powder and oxide of silver were administered.

May 6th. She was convalescent. The mouth was sore, and the face swollen. She had no pain or swelling of abdomen. The skin was moist; the pulse 108; the bowels were open. The lochia were very scanty. The breasts had scarcely swelled. There was pallor of the surface; but the nervous system was tranquil. The patient was of a quiet disposition.

May 8th. She slept in the night. There was now no swelling of the face. She felt comfortable on awaking, and took two cups of tea for breakfast.

At twenty minutes to 9 a.m., she suddenly asked for the bed-pan, and passed, *per vaginam*, bloody clots. She immediately fell into a fainting fit, with slight struggling. On recovering, she said that she required to pass water; but, instead of urine, gushes of blood escaped *per vaginam*, and flooded the bed as low as the patient's feet. Dr. John D. Brown saw her in the course of a few minutes. The hæmorrhage had entirely ceased; but he applied cloths dipped in cold water, and exhibited tincture of cannabis Indica (℥xxv), and, subsequently, acetate of lead. Brandy and wine were administered by the teaspoon every few minutes. The patient's skin was cold and pallid as marble. The pulse was flickering. There was no recurrence of hæmorrhage.

The patient gradually became lower; but consciousness persisted till 2½ p.m., when the agonies of death commenced. She died at ten minutes before 3 p.m.

EXAMINATION OF THE BODY, twenty-six hours after death. There were present Dr. J. D. Brown, Mr. Ely of Chatham, Dr. Ely of Rochester, and myself. Rigor mortis was present. The surface was pallid; the abdomen was not swollen.

The Thorax was not examined.

Abdomen. The intestines were healthy. There was no appearance of inflammation of the peritoneum, nor any serous effusion. The liver was fawn coloured. The spleen was healthy. The kidneys were pale, but healthy.

The uterus was equal in size to a large fist. It was white and firm; it probably weighed twelve or fourteen ounces: it filled the pelvic cavity. The ovaries were like almonds; they were quite healthy. There was purple staining along the spermatic veins, and under the pelvic peritoneum, on the left side. No blood was found effused. Urine was found in the bladder; the interior of which viscus was white and firm.

The os uteri was capable of admitting the tips of four fingers: it was irregular. An old laceration (not deeper than a few lines) existed on the right side, and a recent laceration, equally shallow, on the left side. The posterior surface of the cavity, from the fundus to the cervix and os uteri, was in a rough granular state, showing the attachment of the placenta during life. The back of the uterus could detach the granules, leaving the uterine structure beneath firm and uninjured. The sinuses in the body of

* Cited by Mondière, in Archives Gén. de Méd., 1838.

the uterus were plugged with firm white fibrin. Those in the canal of the cervix (which part was easily distinguishable from the body) were plugged loosely by clots of moderate tenacity. One vessel, capable of admitting a blow-pipe through its whole length, was open, except at its mouth, where there was a loose clot. A large artery on the side of the cervix was entire. No ulceration was found. Two oval thin clots, three inches in length, lay in the cavity of the uterus. One was whitened on one surface. The parietal thickness of the uterus was half an inch at the fundus, seven-eighths of an inch at the angles, and one-fourth of an inch at the cervix.

CASE II. HÆMORRHAGE AFTER THE BIRTH OF THE CHILD: SECONDARY HÆMORRHAGE ON THE THIRTEENTH DAY, AND ON THE TWENTY-FIRST DAY: GASTRO-INTESTINAL DISORDER. Mrs P., aged between 30 and 40, wife of a master tradesman in Rochester, was confined of her ninth child on May 20th, 1852, about 7½ p.m., under the care of Dr. John D. Brown. The labour lasted eight hours. The child was a female, and alive. There was sharp hæmorrhage immediately after the birth. The placenta was thrown off by the uterus, and was readily removed from the vagina; but the hæmorrhage continued until after the application of cold water.

This patient had suffered during her pregnancy with gastric disorder, and a sensation of coldness in the abdomen; from which symptoms she was not free up to the time of her labour. The sanitary condition of the house was exceedingly bad. There was a water-closet opening into the room on the ground-floor used by the family. It was frequented by several persons, and there was, day and night, an intolerable stench, like that of cabbage-water.

May 22nd. The patient vomited in the night and this morning. There was abdominal tenderness and hiccup. The pulse was 100; the tongue moist; the bowels open; the countenance calm. She was bled to 3x; and six or eight leeches were ordered to be applied to the abdomen. Calomel and morphia were prescribed.

May 23rd. There was retching. The bowels had been open six times. Pain was present in the umbilical and the left iliac regions, and in the back. The lochia were moderate. The breasts were full of milk. The urine was removed by the catheter, on account of inability to void it. The pulse was 108-116; the tongue moist. Venesection to 3xx was performed. Very little relief was afforded by the bleeding, but all the pain was removed by a turpentine epithem. Calomel and opium, and prussic acid, were given.

May 24th. Pain was felt in the lumbar regions, and there was frequent vomiting. The patient was bled to 3xvj. The blood-clot was flat and red.

Vespere. There was sweating. The pulse was 120, small; and there was frequent retching. Twelve leeches were applied over the sacrum, a blister to the epigastrium, and blue ointment to the abdomen.

May 25th. She was better; had no pain or vomiting. There was occasional hiccup. The pulse was 120, good; the tongue clean.

May 27th. She was doing well, excepting griping from the mercury.

May 28th. There was some mercurial purging. Logwood and laudanum were prescribed.

June 1st. Pain was present in the back yesterday and to-day; and she had frequent desire to go to stool. A turpentine epithem was applied. Morphia was prescribed; and she was ordered to continue the logwood and laudanum. She became free from pain in the afternoon.

6 p.m. Violent hæmorrhage occurred *per vaginam*. The patient was lying in bed, and had not been sitting up; but she had had a copious motion just previously to the hæmorrhage. Cold water was applied, and the tincture of cannabis Indica given in five minim doses. The hæmorrhage was free till nine o'clock, and entirely subsided by ten p.m. The patient did not seem much affected. The surface was rather cold, and the pulse was weak.

June 2nd. She felt better than previously. The pulse had lost the sharpness and frequency which it formerly

had. There being mercurial purging, an opiate enema was ordered.

June 4th. She was better.

June 9th. She had burning pains in the lower part of the spine yesterday. 9½ a.m. Sudden hæmorrhage *per vaginam* took place. The hæmorrhage was smart but not severe; cold water was applied; and acetate of lead and cannabis Indica given. She had a few bloody stools, with griping.

Vespere. She was comfortable; had no pain; had retched twice. 10 p.m. She was rather faint. A little before midnight, she was seized with fluttering of the heart, flatulence, burning in the sacral region, and coldness of the skin. The pulse was quick and feeble; the tongue anemic. A venous murmur was heard in the neck. A blister was applied over the cæcum. Wine was given; and two grains of oxide of silver every four hours, and seven grains of citrate of quinine and iron every two hours.

June 11th. 4 a.m. The skin was warm and perspiring. She had had six motions, but without blood.

Noon. An opiate enema was ordered.

Vespere. The pulse was 108, febrile; the tongue clean and moist. No pain or purging had occurred since noon.

June 12th. She did not sleep in the night. The pulse was quiet. The bowels had been open four times. Some fluttering of the heart was present. The enemata were continued.

June 13th. Sacral burning had been felt for the last three or four days.

June 14th. Tenesmus was present; and she had three or four motions, without blood.

June 18th. She was doing well. She convalesced very slowly after this date.

July 13th. Vomiting occurred; the bowels were not open. A purgative enema was administered.

July 14th. Vomiting had occurred all night. There was no pyrexia. Purgatives proved inefficacious, until after leeches were applied to the abdomen, and calomel and morphia exhibited. The bowels were well relieved the next day.

July 22nd. Colic was present, without vomiting; it was relieved by a mixture of Dover's powder, rhubarb, scammony, and hartshorn, followed by castor oil.

August 4th. She was much improved in health; and had colour in the cheeks.

August 5th. She had a spasmodic attack, with vomiting.

This patient recovered without any more untoward circumstances, but she did not regain her health until she availed herself of change of air.

CASE III. SECONDARY HÆMORRHAGE ON THE EIGHTH DAY. Mrs. C., aged 27, residing in Chatham, the wife of a young man employed in the dockyard, was confined of her first child (a puny male infant) on May 19th, 1852. The labour lasted nine and a half hours. This patient was of a spare habit, subject to hysterical sensations, and a frequent sufferer from headache. The latter was the result of a diseased state of the antrum maxillare on one side, succeeding to the extraction of a tooth.

Mrs. C. convalesced without a bad symptom till May 26th. She had what she considered her usual headache all the day. In the afternoon, whilst standing and about to return to her bed, (which she had not left many minutes,) a sudden flow of blood, *per vaginam*, occurred. The hæmorrhage ceased spontaneously in a few minutes. The loss was not clearly ascertained; but it would appear that it exceeded a pint.

She did not suffer any bad effects from the hæmorrhage; but she was not discharged till August, on account of sup-puration in both breasts. Each breast constituted an enormous abscess.

REMARKS. Of the three cases related, two occurred in houses with very defective sanitary arrangements. Mrs. Gadfield's house was built on the edge of a stagnant ditch, from which an offensive odour was commonly perceived; and the stench in Mrs. P.'s house from a water-closet was, as before mentioned, intolerable. An attempt was made to

deodorize the place; but the remissness of the friends rendered this measure ineffectual. In Mrs. C.'s house there was nothing of an objectionable nature discovered; but it is possible that there was something faulty in the sanitary condition of the neighbourhood. It is worthy of remark, that the placenta was in each case detached naturally, and within ten minutes.

Chatham, July 30th, 1858.

PUERPERAL CONVULSIONS IN A PRIMIPARA DELIVERED OF TWINS: ADVANTAGES OF CHLOROFORM IN SUCH CASES.

By HENRY RUDGE, Esq.

SINCE the discovery of the superiority of chloroform over ether as an anæsthetic agent, by Professor Simpson of Edinburgh—a discovery destined to render his name immortal—much diversity of opinion has been expressed by accoucheurs, as to the safety and propriety of employing it in labour. It is not my intention to enter upon this field of controversy. My object is to contribute an observation from my own practice, which points out a class of cases in which anæsthesia, induced by chloroform, must be at once recognised as a great boon. I propose to give a simple history of the successful administration of chloroform in a case of puerperal convulsions, occurring in a primipara, during her labour with twins.

CASE. On the 25th of July, at 11 P.M., my assistant, Mr. Boyce, a gentleman of ability and considerable experience in midwifery practice, was called to Mrs. E. M., aged 23. The pains were ineffective, and at considerable intervals. The head presented. She was unusually restless; and it was stated by the nurse that she had been convulsed two or three times previous to the arrival of Mr. Boyce. He remained with her during the night, treating her judiciously. The labour slowly advanced until half-past five o'clock A.M. on the 26th; when, after falling asleep, she was seized with a violent convulsive paroxysm, during which she severely bit her tongue, causing considerable hæmorrhage, before a cork or any substance could be thrust between her teeth. The convulsions were suspended until nine o'clock A.M., when they returned with greater violence, and in frequently succeeding fits. The danger of the patient now being imminent, and the responsibility great, Mr. B. very properly sent for me. On examination, I found the os uteri dilated, and the head presenting. The pains were entirely arrested; and the patient was in strong convulsions, attended with considerable hæmorrhage. Under these circumstances, I quickly procured some chloroform, twenty drops of which were administered at intervals, by means of a folded cambric handkerchief, by my assistant. The effects were magical. The convulsions, after a few inhalations, entirely ceased; and I proceeded to extract the child, which was effected without difficulty. On examination, I found it was a twin case (both females); and a second head presenting, I ruptured the membranes, and extracted the second child without difficulty, with the forceps; and, in consequence of smart hæmorrhage, after a few minutes, I introduced my hand, and carefully extracted the placenta. Leeches and cold applications were applied to the head. After delivery she had, at 3 P.M., one attack of convulsions. She passed a good night; the bowels having been well cleared out. No unpleasant symptom has arisen up to this date.

Mrs. E. M. was not conscious of her delivery; and was much surprised when informed that she had given birth to twins. Both infants are well, and likely to live. I have no hesitation in attributing the favourable issue of this case to the use of chloroform: and I firmly believe that, in skilful hands, it will prove an inestimable boon to the fairest portion of the creation, relieving them from much of the danger and dreadful suffering of tedious and complicated labours—sufferings, the witnessing of which frequently unnerves the strongest of the other sex.

Cominster, Herefordshire, July 31, 1858.

BIBLIOGRAPHICAL NOTICES.

THE PATHOLOGY OF THE BRONCHIO-PULMONARY MUCOUS MEMBRANE. By C. BLACK, M.D., formerly Medical Scholar in Physiology and Comparative Anatomy in the University of London. Part i, pp. 99. Edinburgh: 1853.

Dr. Black has undertaken the task of showing the application of chemistry and the microscope to the investigation of pulmonary diseases; of doing, in fact, for these affections what Bowman, G. Johnson, Simon, and others, have done for the kidney and its diseases. The attempt has not, as far as we are aware, been before made—at any rate, not on so extensive a scale as is here presented before us. Although the work is as yet incomplete, the novelty and interest of the subject will tempt us to present our readers with a pretty full abstract of the author's researches; which we may at once state to form a highly valuable contribution to pathological medicine.

Dr. Black first describes the Structure of the Bronchio-Pulmonary Mucous Membrane. He differs from the majority of histologists, with regard to the question whether the pulmonary epithelium is continued into the ultimate cells. He says:

"If a very thin slice of pulmonary tissue be taken from the surface of the lung, macerated for a short time in distilled water to decolorise it, and be afterwards subjected between two slips of glass to the microscope, each pulmonary cell is seen to have a perfect layer of epithelium." (p. 4.)

The uses of the pulmonary epithelium are to protect the basement membrane on which it rests, and to secrete mucus for the purpose of lubrication. In certain forms of disease, however, the epithelial cells "act the part of true excretory organs, and thus eliminate from the blood the elements of disease, in the same manner as the renal epithelium is believed to eliminate the scarlatinic poison in cases of albuminous nephritis." There is, however, this difference; that the morbid products of the bronchio-pulmonary epithelium are physically and chemically determinable; while those of the renal epithelium, in the instance cited, as yet have eluded our means of research. To this interesting subject we shall presently have occasion to return.

Contrary to the opinion generally expressed, Dr. Black asserts that acetic acid *coagulates* albumen. He says that if to the white of egg pure acetic acid be added, and the mixture stirred with a glass rod for a few minutes, distinct flocculi of coagulated albumen will immediately form; and that, if more acetic acid be added, and the mixture be allowed to stand for a short time, the whole will pass into a firmly coagulated mass. He agrees with Kirkes and Paget, that albumen, coagulated by heat, is soluble in acetic acid, if boiled with it; but he finds, contrary to their statement, that digestion in the acid produces no effect.

The author next proceeds to the investigation of the Diseases of the Bronchio-Pulmonary Mucous Membrane. These he arranges under the following heads:

- I. Inflammatory Diseases;
- II. Diseases for the most part non-inflammatory;
- III. Lesions of Structure.

Inflammation of the Bronchio-Pulmonary Mucous Membrane may be; 1. Simple, acute, or chronic; 2. Sthenic or asthenic; 3. Specific.

Acute inflammation is subdivided into

- I. Simple Acute Epithelial Bronchitis;
- II. Bronchitis involving the Submucous Tissue;
- III. Cellulitis, or Inflammation of the Epithelium of the Pulmonary Cells.

The first pathological condition of Epithelial Bronchitis is that of inordinate congestion of the blood-vessels of the mucous membrane. This produces encroachment on the calibre of the air-tubes, tightness of breathing, and, by pressure on the nerves, cough. At first, there is no discharge from deficient transudation of fluid; but afterwards

tion is poured out more quickly than in the healthy nutrition of the part. The percussion note is not appreciably modified; but the diminution in the diameter of the bronchi gives rise to the production of rhonchi, depending, for their amount of loudness and shrillness, on the smallness of the opening through which the air has to pass, the sharpness, tenseness, and rigidity of its edges, and the rapidity of the current of air.

The indications of treatment are to unload the overburdened capillaries, and to prevent their subsequent distension. The former of these is to be fulfilled by depletion and by augmenting the cutaneous circulation by warm clothing; while the tonic of the capillary walls is to be augmented by the constant breathing of cold air.

The second pathological state of epithelial bronchitis is characterised by an increased secretion of mucus, giving rise to the production of mucous and submucous rhonchi. Dr. Black believes that in this disease "the submucous tissue is not affected, and that the disease consists in an excessive nutrition, arising out of an overplus of nutritive blastema supplied to the basement membrane, and consequently exciting inordinate cell-growth in its epithelial covering". The following is the description of the secretion in this form of disease.

"The secretion, in its simply physical character, resembles at first a thinly viscid fluid, similar to the white of egg considerably diluted by admixture with the solution of an alkali. When, however, a quantity of it is collected together in a vessel, it is sufficiently tenacious to form a mass, which adheres to its sides, and which quits them, on inverting the vessel, in long, ropy, stringy portions or bands.

"Microscopically examined, it consists of well formed mucus-corpuscles, mingled with epithelial or basement patches, floating in a viscid fluid menstruum—the contents of cells which have already liquefied. The epithelial or basement patches are chiefly present in the first portions of the secretion, and are caused by a blighting of their cells by the suspension of the natural fluid transudations from the blood through the basement membrane during the previous stage of the disease. Sometimes these patches are formed entirely of epithelial cells which have almost attained a perfect development, but which yet cohere by their edges, as is shown in the adjoining figure. Had such patches of cells retained their position on the basement membrane a short time longer, they would have undergone a further trifling increase of growth, at the expense of the shred of basement membrane which yet intervenes between their edges, after which they would have fallen apart and become separate, isolated, and distinct cells. While thus united, they, in general, measure from 1-2800th to 1-3100th of an inch; but when they have attained full growth, and exist as separate and distinct cells, they have a diameter from 1-2000th to 1-2500th of an inch.

"Their outline is now well defined, and their surface, which presents a full and globular appearance, shows numerous granules, which have an average diameter of 1-18000th of an inch." (pp. 18-19.)

Dr. Black has sometimes, though not often, been able to observe the action of cilia on the mucus-corpuscles just expelled.

The indications of treatment are: 1. To diminish the supply of nutritive blastema to the basement membrane, and thereby to limit the amount of cell growth upon its free surface: 2. To restore the vital tonic of the bronchial capillaries, and to thus enable them to reduce their quantity of blood to their healthy standard. The first of these reductions is to be fulfilled by abstinence, as much as is practicable, from food and drink, and by exciting other secretions; the second is fulfilled by the breathing of a light, dry, cool—not cold—air. Very cold air, in this stage, would only increase the exhaustion of the vital capillaries. Alkalies, from their power of liquefying mucus, are indicated in all cases of bronchitis from the time of their passing into the second pathological stage. Potassio-tartrate of antimony

exerts a beneficial effect in promoting expectoration, up to a certain point, when its depressing influence on the capillaries tends to maintain the very condition of them which it is the object of the treatment to modify.

Bronchitis involving the Submucous Tissue is next taken into consideration. This differs from epithelial bronchitis in the following particulars.

"Epithelial bronchitis is always acute, whereas the above variety may be either acute or chronic. The former is always sthenic in type; the latter is either sthenic or asthenic. In epithelial bronchitis, the epithelium and basement membrane only are affected; in the above variety, the submucous tissue is likewise involved. In the former, the discharges from the affected membrane consist of epithelial scales or patches, and an excess of the natural secretion; in the latter, certain organic and inorganic bodies are added to the above.

"The effects of epithelial bronchitis are epithelial desquamation or ulceration, and epithelial and basement hypertrophy. Of bronchitis involving the submucous tissue, ulceration, hypertrophy, bronchial abscess, and bronchial obstruction, as primary; and emphysema, bronchial dilatation, and collapse and atrophy of the pulmonary tissue, as secondary." (p. 22.)

This form, in its earlier pathological condition, may be either sthenic or asthenic. Passing over the author's lucid description of the first stage, and of the treatment which he recommends, we come to some very interesting observations on the pathology of the disease in its more advanced form, or what he terms the "second pathological condition".

In epithelial bronchitis, there is an "excessive mucous cell-growth, coupled with epithelial desquamation"; but, in the variety now under consideration, there is also invariably exudation into the submucous tissue. This exudation, the fibrinous portion of which coagulates, forms a nutritive matrix, in which are germinal centres capable of being developed into cells. The phenomena which take place are represented in figure 8.

Fig. 7.—1. Epithelial patch; 2. Mucus-corpuscles.

Fig. 8.—1. Exudation masses; 2. Exudation cells and molecules of fibrine; 3. Epithelial patch; 4. Superficial layer of basement membrane; 5. Entire thickness of basement membrane; 6. Mass of coagulated exudation, showing traces of cell development; 7. Bronchial cast.

Pus cells are also sometimes formed in the exudation. [Of their formation, Dr. Black gives the following explanation.

"They occur when the quantity of exudation is great, and the inflammatory action continues severe; or when a scanty exudation takes place, and continues to be influenced by a slow, persistent inflammation. They originate, like the exudation cells, in the fibrinous portion of the exuded plasma, and are, in fact, no other than such cells modified by the degree and persistence of the inflammation, and the quantity of nutriment which is offered to them. The physical differences which they exhibit consist in a slight difference of colour, to be afterwards explained, and in the presence of a number of granules, which are scattered over the inner surface of their walls, and which have the same chemical composition as the walls themselves. These cells generally measure from 1-2100th to 1-2600th of an inch in their diameter, contain from three to nine granules or nuclei, are

rendered more transparent by the action of acetic acid, and are entirely destroyed by prolonged contact with liquor potassae. Thus, in their chemical reaction, they manifest the same disposition as fibrin and albumen subjected to the same reagents. Hence the identity of composition with these substances, in the distribution, as it were, of which the fibrin represents the cell-walls and nuclei, and the albumen the liquid contents. The conditions which determine their formation may be thus explained. A severe inflammation affects the bronchial membrane, exudation takes place into the submucous tissue, but still the capillary engorgement is maintained in all its intensity. None of the fluid exudation is therefore reabsorbed, neither is the temperature of the part reduced. The necessary stimuli of growth abundantly exist, the result of which is, that the inherent vitality of the exuded fibrin germinates, and rapidly develops cells. Owing, however, to the persistence of capillary engorgement, the nutritive elements offered to the cells are in excess of the demand which is necessary for the complete development of their walls. The overplus of fibrin, still in a state of solution, consequently passes by endosmosis into the cells, in which, from the force of homogeneous attraction between it and the cell-walls, it is precipitated in minute granules or nuclei upon the inner surface of the latter, thus constituting the plastic corpuscles of Bennett. Such cells have now reached the utmost limit of development of which they, as isolated structures, are capable; and in this condition they either admit of being assimilated to the surrounding tissues, under the influence of the vital force which pervades the living organism, or they undergo a process of partial decay, during which they assume the particular character of pus-cells.

"Now, this conversion into pus-cells is due to the action of oxygen on the structures of the plastic corpuscles, by which they undergo an *adipoceros* degeneration, similar to the well known effect produced on dead muscular tissue when exposed to moisture, and to a very partial contact with air. Hence the origin of the fat which invariably forms a chemical constituent of pus; and hence also the colour of the latter fluid, as a consequence of the saponification of such fat by the alkalies present in the exudation. The oxygen necessary for this purpose is, in this particular instance, derived, at least in part, from the air taken into the lungs during respiration; but when maturation occurs at some distance from a mucous surface, or from the surface of the body, it (the oxygen) is supplied by the blood as it passes through the capillaries in the immediate neighbourhood of the affected part." (pp. 29-30.)

In every well marked instance which the author has been able to examine after death, he has found pus-cells forming a part of the exudation into the submucous tissue. The

Fig. 9.—Pus cells from imperfectly vitalised exudation.

irregular appearance which they present, as compared with that of exudation-corpuscles, is well represented in figure 9. Dr. Black concludes, very reasonably, that the presence of these cells indicates an imperfect vitalisation of the fibrin from which they were formed, and

that hence the constitutional powers were deficient.

The sputa in this form of bronchitis at first contain an excess of mucus-corpuscles, mixed with a great number of epithelial scales or patches, and with portions of basement membrane, some consisting of the most superficial layer, and others of the whole thickness. (Fig. 8, 4.) The epithelial and basement patches disappear soon after expectoration has been established; and are replaced by masses of exudation-corpuscles, which are either expelled in an imperfect state (fig. 8, 1), or proceed to the form of plastic cells. After this, they must either enter into structural relation with the surrounding tissues, or be thrown off as pus-cells; in which form they now appear in the sputa.

The microscopic examination of the membrane under this condition has led Dr. Black to some important conclusions. He finds that the points, denuded by the removal of the epithelium and basement membrane, are the only parts at which exudation appears; and he concludes that the doctrine, that pus can be formed on the free surface of mucous membranes, without there being any breach of structure, is opposed to microscopic examination, which teaches—

"That every case of pus from mucous surfaces is invariably preceded by epithelial desquamation, and not unfrequently by ulceration of the basement membrane itself."

This is, to our mind, quite satisfactory; for how can exudation take place unless the epithelium be removed? And, after all, the exudation-corpuscle is only, in such cases, what would be an epithelium cell if it were not hurried through its development; and the pus-cell is the result of diminished vitality. The differences are in degree rather than in kind.

Bronchitic sputa sometimes also contains portions of coagulated fibro-albuminous exudation, occasionally forming casts of the bronchi, in the same way as casts are formed in the renal tubes. They are more common in subacute and semichronic than in acute attacks; and include granules, exudation and plastic-corpuscles, and occasionally pus cells. (Fig. 8, 6 and 7.) In a foot note, Dr. Black points out a strict analogy between these products of bronchitic inflammation, and the casts in acute and chronic desquamative nephritis. The renal casts, he says, are formed by

"1. Vascular engorgement of the capillaries surrounding the uriniferous tubes, arresting for a time the natural transudation of fluid into the basement membrane, with which they lie in contact; 2. Exhaustion of the vital tonicity of these vessels, exudation as a consequence, and desquamation of those portions of epithelium which have perished during the stage of congestion, and the consequent suspension of all natural transudation; 3. The escape from the denuded surfaces of the basement membrane of an exudation, which, when copious, fills the corresponding uriniferous tubes, coagulates, and thus forms a cast, but which, when scanty, remains for some time attached to the basement membrane, on which it coagulates, germinates, and undergoes the same process of cell development as characterises the products of bronchial inflammation." (pp. 34-5.)

The next subject which occupies attention is the chemical analysis of the sputa of acute sthenic bronchitis. The mean of sixteen analyses has given of

	In 100 parts.
Water	96.75
Organic matter	2.15
Alkaline sulphates	1.10
" phosphates	
Chlorides of sodium and potassium	
Sulphate and phosphate of lime	
	100.00

The organic matter is three times as much in proportion as in healthy mucus; while the salts are increased tenfold. Again, in healthy mucus the salts are to the organic matter as 1 to 5.66; in bronchitic sputa, as 1.10 to 2.15. This remarkable increase of the salts is thus explained by the author:

"After the coagulable portion of the exuded plasma has solidified on the denuded surfaces of the basement membrane, a continual supply of alkaline fluid from the blood is required to effect its resolution, before it can be assimilated in the growth and development of cells.

"This supply of alkaline fluid, regularly taking place for some time after all inflammatory exudation has ceased, must necessarily lead to a relative increase of salts, as compared with the organic matter of the sputa, which, according to the analysis before given, is actually the case.

"If we take into consideration the absolute increase of organic matter and salts, as well as the greatly increased quantity of sputa, in acute sthenic bronchitis, we can appreciate the drain which is continually being made upon the blood by this cause alone; and if we further regard the waste produced by all the other secretions, and occasionally by the effects of medicines, as well as the negative result of almost total abstinence from food, we can readily understand how and why the bulk and weight of the body rapidly decrease in disease." (pp. 36-7.)

The indications of treatment in the second pathological condition of submucous bronchitis are to remove the exudation, to favour its tendency to cell development, and to procure its subsequent disintegration. For these purposes, alkalies are *primâ facie* the appropriate means; but, where inspissated mucus and bronchial casts exist, the abstraction

to breathing may be so great, as not to allow sufficient time for the alkalies to gradually disintegrate the causes of obstruction through the medium of the circulation. In these circumstances, we must use emetics, selecting those which are least likely to produce a depressing effect—such as sulphate of zinc, a warm solution of common salt, and mustard. When expectoration fails in consequence of debility, expectorants, such as senega, squills, ammoniacum, and the balsams and oleo-resins, must be employed.

By the term Pulmonary Cellulitis, the author designates an "inflammation confined to the epithelium of the pulmonary cells,—a disease which is extremely prevalent among children, and often regarded as pneumonia, and which is not rare even in adults. It bears the same relation to pneumonia, as epithelial bronchitis does to the severe variety of that disease." With regard to its seat, and other particulars, the author states that

"Cellulitis is more common in the lower than in the upper half of the lungs; in the posterior than in the anterior portion of the lungs; in infants and children than in adults; that it may occur suddenly and at once; or that it may supervene on either the epithelial or the more severe variety of bronchitis; and that, when it occurs in the upper half of the lungs, it is generally dependent on tuberculous or other deposit in the pulmonary tissue." (p. 39.)

From the lucid description given by the author, we condense an account of the phenomena of the first pathological condition of the bronchio-pulmonary membrane in this disease. They are, vascular engorgement, with suspension of secretion; sometimes spasm of the capillary bronchi; diminished diameter of the pulmonary cells, and of the minute bronchi; deficient breathing, and hence increased action of the lungs; cough; a sense of weight and sometimes of burning; dulness on percussion, confined to the affected part; and compensatory action of the opposite lung. This compensatory respiration may take place in one of two ways. In one, the breathing is deep, the ribs on the sound side are unusually elevated during inspiration, and the number of respirations is fewer than when activity of function is the means adopted. In the other, where activity of function prevails, the elevation and eversion of the ribs on the sound side exceed but very slightly, and sometimes not at all, those of the diseased side; but the number of respirations is always increased. The former method is invariably associated with the sthenic, the latter with the asthenic form of cellulitis.

The vesicular murmur is diminished, but not, as in pneumonia, entirely destroyed. Indeed, until the tonicity of the pulmonary capillaries is impaired by the continued pressure of blood upon their walls, a sufficient quantity of air is admitted to produce an increased vesicular murmur, by acting on the as yet contractile walls. As vascular engorgement advances, the vocal resonance increases; and tubular breathing and bronchophony are always present in the affected part, modified, however, by the extent and degree of vascular engorgement, by the portion of lung affected, and by the relation of the bronchial tubes to its surface.

The consideration of the second pathological condition of pulmonary cellulitis leads the author to refer to the much debated question of the origin of crepitant and subcrepitant rhonchi. These he explains by the presence of fluid in the pulmonary cells, the slight irregularities on their surface, and the engorgement of the surrounding vessels. If the quantity of fluid fill the cells at the extreme of expiration, if it be very viscid, and if the breathing be hurried rather than deep, the bubbles formed and burst by the passage of air through the fluid are small and numerous; this is the crepitant rhonchus—a sound seldom heard in cellulitis. But if the breathing, instead of being hurried, is somewhat deep, the bubbles are larger and fewer; and subcrepitant rhonchus is produced—a sound most frequently heard in the second stage of cellulitis. Again, if the breathing is both hurried and deep, or deep only, submucous rhonchus is produced. This is heard in the sinking stage of the disease; in which it is also produced in the minute bronchi.

The sputa, when first discharged, present exactly the

same appearance as the first portion of sputum expelled in bronchitis. (Fig. 7.) Subsequently, in pure cellulitis, the sputa are more consistent, viscid, and tenacious, and present a yellowish or greenish-yellow colour. This sputum Dr. Black believes to be characteristic of cellulitis in contradistinction to pneumonia proper, which is almost invariably characterised by the presence of rust-coloured sputa, from the admixture of blood. When examined under the microscope, the sputum of cellulitis is seen to present the appearances represented in figure 11.

Fig. 11.—1. Portions of basement membrane; 2. Exudation masses and cells; 3. Casts of pulmonary cells; 4. Mucus cells.

If capillary bronchitis be associated with cellulitis, casts of the tubes will also be present. Sometimes the exudation obstructs the bronchi; and then what is called "bronchial abscess" is produced, by accumulation in the cells.

In the sinking stage of the disease, whether it have been of the sthenic or of the asthenic type, the sputa present the microscopic characters delineated in figure 12; and at a

Fig. 12.—1. Epithelial patch; 2. Exudation masses and cells, showing their deficient vitality by their irregular shape; 3. Bronchial casts; 4. Mass of simply coagulated exudation.

still more advanced stage of depression, the appearances represented in figure 13 are seen.

We now come to a most interesting part of Dr. Black's investigations—one in which, to the best of our knowledge, he possesses the merit of originality. We refer to his demonstration of the fact that

"When a constitutional peculiarity, a particular diathesis or another disease, is associated with cellulitis, the exudation from the pulmonary membrane frequently contains evidence of the presence of certain products, dependent on such peculiarity of constitution or other disease in the system."

He has, in this way, found uric acid, oxalate of lime, cyst-

ine, cholesterine, and the colouring matter of the bile, in the sputum of cellulitis.

Fig. 13.—1. Minute and abortive cells and cell walls; 2. Minute basement patches of exudation; 3. Bronchial casts.

In illustration of these facts, the author relates three cases.

In the first case, the patient had acute articular rheumatism, with epithelial bronchitis. On the second day, the urine deposited a thick yellowish red sediment of urate of ammonia: the expectoration was thinly viscid and frothy, consisting of epithelial patches and mucus-corpuscles. During the night, the breathing became oppressed, with weight and burning in the lower and posterior part of the right side of the chest, cough, and partial suppression of expectoration: the physical signs indicated cellulitis. On the third day, the urine deposited urate of ammonia: the expectoration was reestablished, and becoming more copious. It was seen to consist of a few epithelial patches, mucus-corpuscles containing distinct globules of urate of ammonia, free urate of ammonia, exudation masses and cells, and irregularly shaped flakes and masses of fibrin. (Fig. 14.) During

Fig. 14.—1. Epithelial patch; 2. Mucus-cells containing urate of ammonia; 3. Free urate of ammonia; 4. Exudation masses and cells; 5. Casts of cells; 6. Nodules of simply coagulated exudation.

this and the following day, the urate increased in the urine and diminished in the sputa. On the fifth day, no trace could be discovered in the sputa. On the ninth day it reappeared in the sputa, at which time the urine was quite free from it; but on the morning of the eleventh and during the remainder of that day, a copious excretion of the urate took place from the kidneys; and on the following day there was no appearance of it in the sputa. From this time the urate was confined to the urine, in which, on the fourteenth day of the disease, a very copious sediment occurred. The cellulitis henceforth rapidly disappeared: and on the twenty-second day, convalescence from rheumatism was established.

That the globules seen in the sputa were urate of am-

monia, was proved by the production from them of uric acid crystals by the addition of hydrochloric acid, and by the formation of murexide on the addition of nitric acid and ammonia.

In the second case related, a medical student, aged 20, while under treatment for oxaluria, took cold from incautious exposure, and pulmonary cellulitis supervened. On the establishment of the expectorant stage, examination of the sputa proved the occasional presence of urate of ammonia, and of oxalate of lime, particularly at the time when they were being eliminated by the kidneys in small quantity, and were hence accumulating in the blood. Crystals of the oxalate were present in the mucus-corpuscles to a limited extent, being for the most part free in the sputa; but the urate of ammonia was not infrequent in the mucus-cells. In the wood-cut accompanying this case, the form of crystal of oxalate of lime in the sputa is the octohedral: this, with the dumb-bell and ovoid forms, were found in the urine. (Fig. 17.)

Fig. 17.—1. Mucus-cells, containing urate of ammonia and octahedra of oxalate of lime; 2. Mass of exudation cells; 3. Free crystals of oxalate of lime; 4. Mucus-cell containing urate of ammonia only; 5. Coagulated fibrin, showing the commencement of cell development; 6. Exudation cell of full growth; 7. Mucus-cell of full growth; 8. Free urate of ammonia.

In the third case, pulmonary cellulitis supervened on jaundice in a woman lately confined. The sputa exhibited plates of cholesterine.

In all these instances, Dr. Black employed the usual chemical tests, which confirmed the appearances presented under the microscope.

The demonstration of the presence of urinary and biliary products in the exudation and mucus-cells of pulmonary disease, presents several points of interest, both physiologically and pathologically. We could, if our space permitted, perhaps say much on this subject; but at present we will only remark, that the lungs are thereby demonstrated to be capable of performing the function of *secreting glands*. When they take in a vicarious action for other organs, and the secreted matters are chemically deposited within the mucus-cells, we have a proof of their analogy, in function as well as in structure, with other organs containing fine tubes lined by epithelium lying on a basement membrane.

Chronic Bronchitis is described as a continuance of the second pathological condition of bronchitis affecting the submucous tissue. To the epithelial desquamation, exudation into the submucous tissue and on the basement membrane, and increased mucus-cell growth, are added thickening of the submucous and basement membranes, from non-removal of the exudation which is poured out on them. The mucous membrane presents an increased colouration, apparently of a deeper hue in some parts; viz., where the epithelium has been shed. The parts which are unprotected by epithelium are covered with a greyish white exudation, in which are seen a number of nuclear points, manifesting a disposition to exudation cell development. In other parts,

again, the basement membrane is covered with coagulated molecules of exudation plasma; and, as these are more firmly adherent than the masses of exudation, from these are more particularly produced plastic and pus-cells. The basement membrane is also in parts removed, in the whole or in part, of its thickness. With regard to the aid afforded by the presence of basement membrane in the sputa, Dr. Black observes that—

"The presence of basement patches in the sputum is indicative of basement ulceration; but their absence is by no means diagnostic of the integrity of that structure, inasmuch as the latter may become so charged with inflammatory exudation, that when such exudation undergoes cell development, it may thereby break up the basement membrane, in the same manner as tuberculous deposits will hereafter be shewn to break up the pulmonary tissue, and that, too, into such minute portions that the original structure admits no longer of recognition. Hence, from the above facts, the advantage to be derived, in reference to diagnosis and prognosis, from microscopic examination of bronchitic sputa." (p. 60.)

When chronic bronchitis has lasted many months, and has been of rather slow progress, there is a minor degree of coloration and puffiness, but considerable thickening, consolidation, and more or less firmness and rigidity of the bronchial tissues generally, due to the progressive organisation of the exudation; the quantity received exceeding that which is discharged. This gives rise to a narrowing of the tubes. It is chiefly manifested in cases of chronic capillary bronchitis, attended with a certain amount of constitutional vigour; and, according to the author, is generally met with in otherwise healthy subjects, from the forty-fifth to the sixtieth year of age. But, after the latter of these periods, bronchitis—

"Owing to the natural disposition to decay which now, in obedience to the immutable laws of nature, pervades every tissue—to the consequent excess of molecular disintegration, as compared with molecular nutrition—and to the looseness and laxity of tissue thereby occasioned, assumes more particularly the character of atonic inflammation of the bronchi; whilst, owing to the deficiency of the nutritive principles of the blood, as compared with early life, the products of this pathological condition exhibit but few of the characteristic structures of inflammation. There are, therefore, various shades of chronic bronchitis, some of which are characterised by a certain degree of constitutional power, others, by the sheer debility attendant on natural decay. The former cases are liable to the sudden supervention of acute attacks of bronchial inflammation; while the latter are not thus influenced. Again, the former may be limited in the extent of the membrane involved; nevertheless, they invariably extend: the latter are more general in the extent of surface affected, but they are always stationary. Of the former kind, plastic bronchitis is an extreme example; of the latter, senile bronchitis. These extremes approach each other by cases of intermediate severity, each of which, by the character of its sputa, indicates, to a considerable extent, the particular pathological condition of the bronchial membrane which exists." (pp. 61-2.)

To the examination of the sputa in these cases, we shall presently return.

We are reluctantly obliged to pass by several interesting subjects, connected with the effects produced in this disease on the respiratory phenomena, and on the cough, and on the nutrition of the system.

The next subject which meets our notice, is the examination of the sputa in the four following varieties of chronic bronchitis:—

1. Plastic Bronchitis.
2. Early stage of simple Chronic Bronchitis.
3. Latter stage of simple Chronic Bronchitis.
4. Senile Bronchitis.

The characters of these sputa may thus be briefly exhibited:—

1. *Plastic Bronchitis. General Appearance.* Coats of bronchial tubes, solid or tubular; from 1-1000 of an inch to several inches in length; in latter case branched; of bluish-white or dirty yellowish-white colour; soft, and frequently streaked with blood; when tubular, they collapse, and appear as flattened bands. *Microscopic Appearances.* They frequently consist of a fibrous tissue, on which rests a base-

ment structure, surmounted by an imperfectly developed epithelium. If not connected with a tuberculous diathesis, they present a fibrillar arrangement, interspersed with exudation cells: but if of tuberculous origin, they are rather distinguished by an amorphous or granular state of the exudation.

2. *Early stage of simple Chronic Bronchitis. General Appearance.* Drab coloured, viscid, ropy matter, of consistence slightly less than that of white of egg; containing minute portions of yellow or yellowish-white substances, giving a mottled or corrugated appearance. *Microscopic Appearance.* The sputum contains numerous well formed and very granular mucus-corpuscles; patches and masses of coagulated exudation, some being opaque, others partially transparent; together with exudation cells, basement patches, plastic and pus cells, bronchial casts, a few epithelial scales, and granular or amorphous deposit of the sulphate and phosphate of lime. These appearances are represented in figure 18.

Fig. 18.—1. Mucus corpuscles; 2. Coagulated exudation mass; 3. Exudation cell; 4. Basement patches; 5. Plastic cell; 6. Pus cells; 7. Bronchial cast; 8. Epithelial patch.

Chemical Composition. The mean of twelve analyses gave Dr. Black the following result:—

Water	97.36
Organic matter	1.72
Chlorides of sodium and potassium	
Alkaline sulphates and phosphates	.92
Sulphate and phosphate of lime	
	100.00

3. *Latter stage of simple Chronic Bronchitis. General Characters.* The sputum is less tenacious, consistent, and variegated than in the former variety. It resembles a thinly diluted and dirty drab serum, in which grey, yellowish-grey, or greyish-white flocculi, and isolated irregular looking masses are suspended; which, after rest for a few hours, sink to the bottom of the vessel. *Microscopic Appearances.* The structures exhibited are the same as in the former variety; but they are fewer in number, and exhibit a lower degree of development. *Chemical Composition.* According to the mean of eight analyses, the composition of the sputum in this form of disease is—

Water	98.83
Organic matter	1.02
Chlorides of sodium and potassium	
Alkaline sulphates and phosphates	.15
Sulphate and phosphate of lime	
	100.00

4. *Senile Bronchitis. General Appearances.* The colour and consistence of the sputum are similar to those of a thin solution of gum, through which numerous small, irregular, yellowish-white or drab, flocculent, and semi-solid bodies are dispersed, which, after a short time, sink to the bottom, and occupy about 1-14 of the height of the fluid. *Microscopic Appearances.* The supernatant fluid consists of a

thin menstruum, containing numerous nodules of fibrine, from 1-1000 to 1-18,000 of an inch in diameter: a few isolated exudation cells; a few superficial basement patches; and a very scanty proportion of irregularly oval mucus corpuscles.

Fig. 19.—1. Basement patches; 2. Mass of coagulated exudation, showing traces of cell development; 3. Mucus-corpuscles; 4. Exudation masses, showing diminutive cell growth; 5. Thin layer of exudation, showing cell development at points of its surface; 6. Bronchial cast; 7. Collapsed blood-disc.

The sediment exhibits the same scanty numerical proportion of mucus-cells. There are, in addition, a few isolated exudation cells. The number of exudation masses is great; but they present a mere trace of cell development. There are also present superficial basement patches, bronchial casts, sometimes a few pus cells and blood globules, and thin, transparent, irregularly formed layers of coagulated exudation.

Chemical Analysis. The mean of six analyses gave the following composition:—

Water	99.14
Organic matter	.72
Chlorides of sodium and potassium	
Alkaline sulphates and phosphates	.14
Sulphate and phosphate of lime	
	100.00

For the explanation of the pathology of these forms of sputa, we must refer our readers to Dr. Black's Essay, promising them that they will find much to repay a careful perusal. We must also pass over, with a similar recommendation to attention, his remarks on the treatment of Chronic Bronchitis, and on Specific Inflammation of the Bronchio-pulmonary Membrane.

Dr. Black concludes his work, so far as it has been presented to us, with an examination of the following question: "How far are the different forms of Asthma dependent on inflammation of the bronchio-pulmonary membrane?"

He recognised two distinct forms of asthma—

"One in which the paroxysm comes on suddenly, and is followed by an interval of perfect ease, during which there is neither the slightest difficulty of breathing, nor the least increase of the bronchio-pulmonary secretion; the other, in which the invasion of the paroxysm is more gradual, in which there is more or less straitened breathing during the interval, and in which the secretion of the membrane is somewhat greater than that of health, and is also changed as to its physical appearance to the naked eye, as well as being microscopically and chemically different." (p. 85.)

The first of these forms he dismisses with a few remarks, referring it to disorder of the general health, or to some local disease apart from the lungs. With regard to the mode of attack, the term "nervous asthma" is appropriate; but, looking to the pathological cause, that of "symptomatic asthma" is more applicable.

The second form embraces the majority of cases, and includes all the varieties of true spasmodic asthma.

The history of these cases points, in nearly every case, to their origin in chronic bronchitis; and this is confirmed by

inspection of the bronchio-pulmonary membrane, and by microscopic examination of the sputa. Dr. Black also finds hypertrophy of the structures composing the membrane, and a manifest increase in diameter in the bronchial muscular fibres, in all cases which have manifested a distinctly spasmodic character before death. He has likewise found thickening of the coats of the vessels; and, in several cases, a degree of hypertrophy of the sentient nerves.

At a more advanced period, a stage arrives, in which distinct paroxysms of dyspnoea cease to occur. The degree of respiration has been permanently brought below the standard of health; and this is attended with a diminution in the bulk of the body. The sputum in this state consists of fully formed mucus and pus-cells, the latter being numerous; and of exudation-cells. There are also a few superficial basement patches, a few minute opaque nodules of fibrin, and transparent irregular layers of exudation plasma. Very few bronchial casts, and as few epithelial patches, are found. The structures composing the mucous membrane have undergone a process of matting together; while the circular and longitudinal fibres are hypertrophied and so amalgamated, that their power of contracting is in a great measure lost. We also find occlusion of the bronchi, lobular collapse, and vesicular emphysema.

To explain the occurrence of spasmodic asthma, Dr. Black has performed some experiments in order to show the properties of the bronchial muscular fibre, and its influence in the production of the asthmatic paroxysms.

Volkman has asserted that galvanism, applied to the vagus nerve, will cause contraction of the bronchial muscles; and he states that a lighted taper, placed opposite to the open end of the trachea, could be in this way extinguished. Dr. Black relates four experiments which he performed with the pulmonary organs of animals, in which he applied galvanism both to the pneumogastric and to the sympathetic nerves, without producing the result described by Volkman. On applying the galvanic stimulus to the lungs, or to denuded portions of the bronchi, the end of the trachea being directed beneath the surface of water, bubbles of air escaped through the water, showing the contractility of the bronchial fibres. In some of the experiments, the smallest bronchi were observed to contract during the experiment. For the details of these experiments, we must refer to the work itself; merely stating the results at which Dr. Black has arrived.

"The result of these experiments shows that the muscular fibre of the bronchi, as also the fibrous tissue of the mucous lining, is endowed with the power of contractility; that this property is excited by stimuli directly applied to it; that it is highly questionable whether such property can be called into action by stimulation of the trunks of the bronchio-pulmonary nerves; that the mode of contraction is similar to that of the non-striated muscular fibre, commencing at the point of stimulation, and gradually propagating itself to neighbouring fibres; that the expulsion of air from the minute bronchi is, by virtue of their structure, more rapid than from the larger bronchi; that, in the latter tubes, the presence of their cartilages, the consequently limited action of their muscular fibres, and the greatly increased area of such tubes passively retard, rather than actively augment, the speed of the outward column of air set in motion by contraction of the smaller bronchi; that this negative opposition of forces is further increased in the trachea; and that, therefore, the expulsion of air from the lungs can never, under the above circumstances (*i.e.*, unaided by contraction of the expiratory muscles), take place in a forcible manner; but must, on the contrary, be a slow, continued, or intermittent oozing of air, according to the continued or intermittent action of the cause of the contraction of the bronchial and other fibres." (p. 91.)

According to Dr. Black, the longitudinal and circular fibres of the bronchio-pulmonary membrane take an important part in the act of respiration; and he gives the following formula, as representing the expiratory forces:—

During the commencement of Expiration, { Vesicular and Bronchial Contraction, maximum.
Muscular Contraction, minimum.

At end of Expiration, { Bronchial Contraction, minimum.
Muscular Contraction, maximum.

The term "muscular contraction" is applied to the external respiratory muscles.

To illustrate the direction of the action of the component forces of the longitudinal and circular fibres of the minute bronchi, Dr. Black makes a happy application of the principle of the *parallelogram of forces*.

Fig. 20.

"Let $A B$ represent the axis of a portion of the bronchial tube; $C D, E F$, two of its longitudinal fibres, directly opposite to each other, so that a plane passing through them would likewise pass through the axis $A B$; and let a, b, c, d , be circular fibres, and n a radius of one of the circles. Now, if we suppose the expansive and contractile forces of the circular fibres to be in operation, it is evident that the circumferences of these circles, and likewise their radii, increase and decrease respectively. It is also evident that, if the forces of the circular fibres alone are in operation, motion of any point n takes place in the direction of the radius $n r$, because n is the extremity of that radius, which increases or decreases during the act of expansion or contraction. But we have likewise the expansive and contractile forces of the longitudinal fibres in operation, which tend to move the point n in the direction $c d$. Hence, by the principle of the parallelogram of forces, motion of that point takes place in the direction of a straight line, $m n e$, lying in the plane $C D E F$, and passing obliquely through the centre of the tube, with an angle, $m e r$, greater or less, according as the ratio of the expansive and contractile forces of the circular fibres to those of the longitudinal is greater or less.

"From the above representation, it is evident, that the expansion and contraction of the minute bronchi are in the diagonal of a parallelogram described on one of the longitudinal fibres, the sides of which parallelogram represent the two forces of the longitudinal and circular fibres; and we have only to conceive the maintenance of the contraction of these fibres at any and all points of their range of action, to understand the proximate cause and the different degrees of the asthmatic paroxysm." (pp. 94, 95.)

The author then notices bronchial dilatation, which he explains on the principle of unequal progress of disease, parts of the tube having lost their contractile power, while other parts are free. The production of dilatation is further favoured when the complete or partial obliteration of some bronchi causes an excessive quantity of air to be forced into others.

The proximate of spasmodic asthma being an irregular contraction of the bronchial fibres, the next question to be determined is, On what pathological condition does it depend? Dr. Black does not believe that the nerves have any influence; and that, therefore, the direct cause of the contraction cannot exist at a remote part of the system. With this view, we can scarcely at present agree. It does not follow that, because Dr. Black has failed in producing contraction of the bronchi by stimulating the vagus nerves of healthy animals, a diseased bronchio-pulmonary structure may not be liable to inordinate muscular contraction, from stimulation of its afferent nerves through disorder of some other part of the system. And we cannot imagine such a well marked line of distinction between the cases of true *sympathetic* asthma, and those of spasmodic asthma connected with bronchitis. Further, we find the author, a page or two further on, referring to indications of treatment derived from the "presence of undigested food in the stomach". This, and other forms of gastric and hepatic derangement, certainly sometimes excite or aggravate the asthmatic paroxysm. At the same time, we fully admit, with Dr. Black, that the necessary pathological condition is

inflammation of the bronchio-pulmonary mucous membrane and its consequences.

Returning to the exciting causes, we find the author referring them exclusively to agents acting locally on the diseased membrane, viz., sudden reduction in the atmospheric temperature; inhalation of irritating vapours, or of dust; accumulation of mucus; vascular congestion of the membrane; and possibly the slight retention of carbonic acid in the blood; the two latter causes operating principally during sleep.

In the treatment of true spasmodic asthma, the indications, in order to obtain permanent benefit, are those of chronic bronchitis; while the indications during the paroxysm are thus concisely explained:—

"1. To relieve spasm of the bronchial fibres.

"2. To withdraw the exciting cause, and to correct any condition of the system which may indirectly contribute to an attack.

"The spasm is relieved by the exhibition of ether, opium and its different preparations; by lobelia inflata, camphor, conium, henbane; by extensive counterirritation to the chest, and by the cautious inhalation of chloroform when no cardiac disease exists. Benefit is likewise derived from the use of assafetida and turpentine enemata; and, during the intervals of the paroxysm, from the exhibition of belladonna and stramonium, in conjunction with the remedies already indicated in the treatment of chronic bronchitis.

"In withdrawing the exciting cause, regard must be had to its particular nature. If it depends on any irritating qualities of the air breathed, these must, as far as is practicable, be obviated, by removal to the more congenial air of another apartment. If, on suddenly increased vascular engorgement of the bronchio-pulmonary capillaries, derivation to the skin should be energetically solicited by counterirritation to the chest, the warm stimulating pediluvium, by warmth to the general surface, in the form of warm water or vapour bath, and by the internal administration of the acetate of ammonia, camphor julep, coffee, and the different carminatives, followed immediately by a brisk purgative. If on the accumulation of mucus in the bronchi, or the presence of indigested food in the stomach, an emetic of antimony, ipecacuanha, or the sulphate of zinc, must be exhibited, according to the particular features of the case,—antimony being the preferable where the patient manifests a moderate degree of constitutional vigour, and ipecacuanha or the sulphate of zinc in cases attended by marked debility.

"To correct any condition of the system which may indirectly contribute to an attack, it will be necessary to inquire into the state of the general functions, and particularly those of the digestive organs, and to treat any deflection from the standard of health according to the recognised principles established by experience." (pp. 89, 99.)

The copious analysis which we have given of Dr. Black's work will, we believe, sufficiently justify us in declaring it to be one of the most valuable contributions, as far as it has gone, to the pathology of diseases of the pulmonary organs, which we have ever met with. The application of the microscope and the test-tube in the investigation of disease was, a very few years ago, an acquirement confined to a favoured few; but the day is evidently coming, when the physician who is not able to make at least a certain degree of use of them will be regarded in the same light as would now be one who was ignorant of the application of the stethoscope. Dr. Black has made an advance in the right direction; but while he brings prominently forward the value of chemistry and the microscope, as aids in the investigation of chest-diseases, he does not underrate the stethoscope and the pleximeter; and his remarks on treatment are on the whole highly judicious. We trust that he will not long delay presenting the profession with the results of his examination into other diseases of the respiratory organs.

We may here state that, in order that the descriptions transferred to our pages might be more easily apprehended by our readers, we applied to Dr. Black for the loan of some of the woodcuts with which his work is illustrated. Dr. Black at once more than acceded to our request, by placing the whole of them at our disposal.

EVERY MOTHER'S BOOK: Plain Advice on the Management and Diet of Infants, with Observations on the Symptoms of the Diseases to which they are liable. By WILLIAM PEARCE, Esq. 12mo., pp. 46. London: 1853.

WE cannot commend this tract. It contains certainly some truths, but it likewise contains errors of serious magnitude. Take for example the following passage:—

"Where the unfortunate mother has surrendered her own life in giving birth to the infant which survives her, or where, from malformation of the breast, or other causes, it is impossible for the mother to suckle her child, we must endeavour to provide something as nearly as possible similar to the milk which, under more fortunate circumstances, the child would have received. Good cow's milk, prepared according to the following form, is an excellent substitute for mother's milk in the early months of feeding:—

"Take half an ounce of fresh mutton suet, cut into small pieces, and tie them in a muslin bag, taking care that they are not pressed upon; boil in a pint of cow's milk, to which half an ounce of good oatmeal and a teaspoonful of powdered sugar candy have been added.

"Of this give an ounce (*two tablespoonfuls*) every two hours, or a smaller quantity more frequently." (p. 15.)

We have had a considerable experience in directing and observing minutely the rearing of infants upon a substitute for mother's milk. We never allow a healthy infant, for the first two months, to have any other food as a substitute for its mother's milk than cow's milk diluted with two-thirds of water, and well sweetened with fine sugar. Of this fare we sanction an *unlimited supply*, at intervals of from one and a half hours during the day, and three or four hours at night, provided it be sucked from a teat. Upon this simple fare, we have seen children grow up in the plenitude of health and strength. If the food be as thin as we have described, no evil can arise from overfeeding: and by allowing an interval to elapse between the times of feeding, digestion goes on better, and fretfulness is averted. To weak or scrofulous infants, the addition of a little mutton suet is good, or the same benefit may be obtained by giving two teaspoonfuls of cod liver oil daily. Oatmeal, and all farinaceous foods, are unsuitable and unnatural for the first two months, and are certain to induce fits of feverishness and griping pains. How oatmeal should be set down in the above receipt, we cannot imagine. After the second month, rusk, melted down in the sweetened milk and water, is useful; but the food must still be thin, and sucked from a teat by the infant. The exertion of sucking is, for many reasons, very salutary.

EDITOR'S LETTER BOX.

CHLOROFORM IN MIDWIFERY.

LETTER FROM F. H. RAMSBOTHAM, M.D., TO THE EDITOR.

SIR,—In the number of your Journal for June 19th, which did not come under my notice till a few days ago, there is a paper by my friend Dr. Snow, on the exhibition of chloroform in obstetric practice. He notices a case that proved fatal, subsequently to the inhalation of that drug,—reported by me in the last edition of my *Principles of Obstetric Medicine*,—in a manner which might lead your readers to suppose that the patient referred to had been under my own care. This was not the case: I obtained the history from a friend, who conducted it, who kindly supplied me with the facts, and permitted me to publish them.

Although I am quite sure the chloroform was given with caution and judgment; and although I consider the treatment, after the dangerous symptoms had appeared, as the best that could have been devised; nevertheless I think it right to state thus much, that no misapprehension may exist.

Dr. Snow says, "he doubts whether I would have considered this death as due to the medicine, if I had had extensive experience in the use of chloroform, either in obstetric, or any other class of cases." I have myself seen quite enough of the action of this medicine, and a sufficient number of deaths under its

use have been reported, to impress me with the conviction that chloroform can in no case be given, to the production of an *entire annihilation of the mental faculties*, and the *complete destruction of sensation*, without some risk; and, in regard to the instance under discussion, notwithstanding Dr. Snow's authority, I am still of opinion that the fatal event was occasioned by the inhalation.

Dr. Snow argues that, as the symptoms I have detailed differ from those hitherto observed in poisoning by chloroform, therefore they must be referred to some other cause, probably disorganisation of the kidneys; and, in confirmation of his view, he gives the outline of a case with similar symptoms, that occurred under the hands of Dr. Murphy, in which chloroform was taken, and where granular degeneration of the kidney was detected on dissection.

As no *post mortem* examination was made in the case that I have put on record, we must remain in the dark as to the condition of the internal organs; but, as I never saw such symptoms supervene after labour as those that appeared in that case, and as I do not recollect of any such on record, I think we may fairly refer them to the chloroform itself. It is not unlikely, indeed, that some organic disease might have been lurking in the system; but the question raised ought to be, not whether any important organ was the subject of degeneration, but whether, if that were so, the train of unhealthy action, which terminated in death, did not arise from the influence of the medicine on the diseased structures; or, in other words, whether the lady would have died in this way, if chloroform had not been exhibited. I cannot help believing that such would not have happened; and therefore attribute the distressing result to the noxious qualities of the drug.

With respect to a case of puerperal mania following the administration of chloroform, which I have alluded to in the same work, but without going into particulars, Dr. Snow remarks that "I do not state at what period after labour the mania commenced; whether, for instance, an hour or a month." He is quite correct; for I merely mentioned the case casually for the purpose of illustrating an argument not strictly professional, and did not propose to detail it. But, being called upon in this way, I may be allowed to state, that the first decidedly maniacal symptoms shewed themselves within three or four days after delivery, as far as I can recollect; and that the account given to me when I saw the lady induced me to believe that she had never been quite herself since her labour. I was told that she had scarcely slept; and that, until her mind succumbed, she was constantly exclaiming, "Oh! that chloroform; I cannot get rid of the smell of that chloroform!"

Dr. Snow remarks, "it is well known that out of the vast number of patients, to whom this agent has been administered for the performance of capital operations, a few have unfortunately died while inhaling it, or a minute or two afterwards; but it is satisfactory to know that no accident of the kind has happened in the practice of midwifery." Dr. Snow should rather have said that no case of the kind has come before the notice of the public. We can be by no means sure that such cases may not have happened, though they have not been made known. I sincerely hope I may be wrong in this supposition; and that future experience may demonstrate that these vapours can be administered under labour, not only with safety, but with all the advantages that their advocates teach us to expect from them. It does not require a great stretch of credulity, to believe that every one who possessed the least spark of humanity would receive with joy and gratitude so easy a method of abrogating or assuaging the pains of parturition, if only it can be proved that the practice is void of danger.

Dr. Snow truly says, "when the practice of inhalation in midwifery was first introduced by Dr. Simpson, he adopted the plan, which is universally followed in surgical operations, of making the patient unconscious at once, and keeping her so to the end of her labour." It was against this thorough subversion of mental consciousness as well as personal sensibility, thought it might be comparatively temporary, that I ventured to raise a warning voice. Believing, as I did, that we are not warranted in encountering the hazard attendant upon such a complete prostration of the faculties as was then insisted on, merely for the purpose of deadening the physiological pains of parturition, I considered that I should not be doing my duty, as a public teacher, if I withheld from my professional brethren the fears with which my own mind was so deeply imbued.

Contrary to the belief formerly entertained, it is now said (and from the trials I have myself made, I have no doubt with truth) that a large proportion of the suffering of labour can be removed by placing the patient only partially under the influence of the

anæsthetic vapour; that it may be administered indeed, with great relief to pain, in such a modified degree, as that not only shall consciousness not be destroyed, but that the integrity of the mind shall be preserved nearly perfect. If that be so, the chief objection to the practice vanishes, at least when entrusted to judicious hands.

Here, however, we are met, *in limine*, by a serious obstacle; for before we can assure ourselves that we really possess the power of invariably producing only a mitigated impression, we ought to determine whether we can calculate on the inhalation of a certain quantity of vapour, within a given space of time, being universally attended by the same phenomena, in every patient subjected to its use. We know that this is by no means the case; but that different individuals, as well as the same individual upon different occasions, are affected by the same quantity of vapour, inhaled within the same period of time, in a manner so various as to create both surprise and perplexity. We have learnt, also, that the influence of the drug is not confined either to the quantity inhaled, or to the time employed; but that the degree of concentration in which the vapour is received into the lungs, as Dr. Snow himself has demonstrated, is the most material of all the circumstances that regulate its potency.

It follows, therefore, as a natural consequence, that we are very liable to be defeated in our attempts to insure only a moderated effect; that, although we may stay our hand just at the point where we expect that a particular state of insensibility has been arrived at, we may nevertheless have already passed beyond the bounds of safety; and we may have impressed the patient's system to a dangerous, or even fatal extent. The numerous cases of sudden, or rather instantaneous death, both on the continent and in this country, in which a comparatively minute dose of the anæsthetic was administered—and that, too, with the advantage of the most experienced assistance—fully confirm the truth of this position.

Notwithstanding the difficulty and obscurity in which this part of the subject is at present involved, it appears to me perfectly possible to let in a much clearer light upon it than it has hitherto received. This might be accomplished by the publication of a faithful record of cases where the nervous system has been but partially blunted, with a notification of the degree in which sensibility, sensation, and volition, seemed to be each individually affected. A mass of most valuable evidence might thus be accumulated, from which it would be easy to lay down some fixed principles for our guidance; so as to dispel the uncertainty and doubt that as yet clog our judgment, and proportionably embarrass our proceedings.

I am, etc.,

FRANCIS H. RAMSBOTHAM.

7 Portman Square, August 5th, 1853.

ASIATIC CHOLERA AND THE ROYAL COLLEGE OF PHYSICIANS.

LETTER TO THE EDITOR.

SIR,—The second fatal outbreak of Asiatic Cholera in 1849, found the medical profession of this country but little more prepared to grapple with the disease than on its first appearance in 1832. Its contagious or non-contagious nature,—what local circumstances gave an impetus to its epidemic influences,—what remedies most surely control its virulent attacks,—are questions which, with several others, were mooted indeed, but not satisfactorily answered. The works of Indian practitioners were not altogether adapted to meet the wants of this country; and English medical literature failed to supply the desideratum. So unprepared, in short, were the profession for the second encounter with their mortal foe, that they were more thoroughly worsted in the contest than before. Whether this was owing to a more formidable type of the disease or not, I shall not stop to inquire. But one opinion, however, seized the public mind; and that was, that medical men were not, on this point, up to the mark, and that the interests of society demanded fresh efforts on their part, if they would retain public confidence. Of this temporary distrust, quackery in its homœopathic and other forms largely took advantage. The Provincial Medical and Surgical Association and the Royal College of Physicians were both alike roused to institute the needful inquiries, and to bring into one focus all that had been observed by the awakened curiosity of the profession. Meanwhile, not a few works on cholera, of considerable merit, the productions of distinguished individuals, made their appearance, with all the advantages of an advanced chemistry and microscopic research. Your readers are familiar with the results of the labours of the former of

those learned bodies; for, like the sharp-shooters of an army, their movements were executed with a celerity, that did the Association infinite credit. Thanks were very properly voted, at its eighteenth anniversary, both to Mr. Hunt, of Bedford Square, London, for his strenuous exertions to obtain information from different localities, and to Dr. Williams, of Worcester, for his able abstract from the replies to Mr. Hunt's circulars. But as to the labours of the College, the issue proves the truth of the adage, that, in spite even of the impetus given to men's minds in railway times, still "heavy bodies move slowly!" Circulars, indeed, were issued from Pall Mall, now some four years ago, to all the members of that learned fraternity, with questions at once pertinent and weighty; and everything promised well for the much needed information of the profession, and the satisfaction of the country. But year after year has dragged its lazy length along, and still no report is forthcoming. How is this? Your proximity to head quarters will perhaps enable you to throw some light on a delay as inimical to the welfare of society, as it is scarcely creditable to a College, to which the country looks up for guidance on great emergencies. What heightens the public impatience is, that a hitherto irresistible and victorious enemy is again, for the third time, thundering at our gates. Slowly emerging from its malarious haunts in the East, the Asiatic Cholera has again travelled northwards, and is now bending its way with gigantic strides to the West of Europe, and is actually within a few days' sail of our shores. Surely, the Asiatic Cholera Report of the Royal College of Physicians will be printed and published without a moment's further delay; or its appearance, after a third visitation of the pestilence over which it will have exercised no influence, will challenge the reproaches of all reflecting men.

I am, etc., PERCONTATOR.

August 3rd, 1853.

NEWS AND TOPICS OF THE DAY.

TRIALS FOR PROCURING ABORTION.

At the York Assizes, on Friday, July 15th, Margaret Simpson, aged 33, was charged with having feloniously caused Mary Fielding to take a noxious drug, with intent to procure abortion. The young woman having formed the acquaintance of a young man (Moore), found herself *enchantée*. She made known her condition to him, when he advised her to call on the prisoner. The prisoner gave her a bottle containing a liquid, and a powder, telling her to take twenty-four drops of the former on a piece of lump sugar, and the powder at twice. The liquid in the bottle was found to contain oil of savin, cantharides, and pennyroyal, the effect of a large dose of which on a pregnant woman might, according to the evidence of a surgeon examined, produce abortion. The powder was colocynth, and, used along with the liquid, would have the same tendency. "Guilty". Sentence deferred.

Auguste Wilhelm, aged 26, was then charged with having used a certain instrument to procure abortion. The prosecutrix in this case was the same as in the last. It appeared that the medicine she had taken not having produced the effect intended, she had been persuaded by Moore to visit the prisoner, who practised as a German quack doctor at Halifax; he told her the safest mode of administering the medicines, which would get rid of the child, was by an injection. After some persuasion, she was induced to allow him to use a syringe, which contained some liquid like porter in appearance. The application gave her no pain. His Lordship was of opinion that this was not using an instrument with intent to procure abortion within the meaning of the statute. The syringe was a vessel merely containing a liquid, which must be proved to be a noxious drug, to bring the case within the meaning of the first part of the section of the statute. The prisoner, in cross-examination of Mary Fielding, elicited that Moore had been accused of labouring under a loathsome disease at the time that this occurred, and that he told witness he was poorly, and that the prisoner was attending him. The prisoner then stated, that he had used the syringe on the person of the prosecutrix, supposing she was ill of the same disorder (knowing from Moore that she was intimate with him), for the purpose of curing her, as she complained of being ill, and he understood that to be her illness. His Lordship directed the jury to acquit the prisoner.

At the Oxford Assizes, Joseph James, labourer, was charged with feloniously administering savin to Ann Clarke, with intent to procure abortion. The case against the prisoner was proved by the young woman, Ann Clarke, a domestic servant, who stated that she had become in the family way by the prisoner, a farm servant, and that when she informed him of her state, he proposed to give her something which would procure abortion. He gave her something in three bottles, which she took, and also some powder. This produced sickness. The young woman was carried into court in a state of partial paralysis, and far advanced in pregnancy. Mr. Lamb stated that he had examined the remains of the drug found in one of the bottles, and, in his opinion, it consisted of an infusion or decoction of the leaves and twigs of savin. He stated, that this drug was generally believed to have the property of causing abortion; but, in his opinion, this was a vulgar error. It would produce vomiting and purging. Mr. Justice Coleridge told the jury the question was, whether the prisoner had administered savin or any noxious thing with the intent alleged. The medical man had stated, that it was a vulgar error to suppose that savin would procure abortion; but he (Mr. Justice Coleridge) thought the authority of Dr. Taylor was sufficient to show that savin, by the shock which it produced, might not only cause abortion, but destroy the life of the mother. The jury found the prisoner "Guilty". Sentenced to six months' imprisonment, with hard labour.

INQUEST AT BRADFORD ON A VICTIM OF COFFINITE QUACKERY. The *Bradford Observer* of July 28, contains an account of an inquest held in that town on the 25th of that month, on a young woman named Sarah Barraclough, a servant, who died while under treatment by a herbalist doctor of the name of Airey. Her disease appears to have been an attack of fever, for which she had at first the attendance of a regular practitioner (Mr. Douglas of Bradford); but subsequently the parents called in Airey, who treated the girl in the following manner, as described by himself in evidence:—

"I told my wife the case, and said that she might treat it as she thought proper. I did not tell her what to get. I afterwards gave her some herbs—some meadow sweet, yarrow, and a little dwarf elder. They were in a bunch. I had nothing to do with the powder; she took it herself. I told my wife that an injection and a little medicine—the meadow sweet, the yarrow, and the elder—to produce perspiration would be useful. I said nothing about the powder. I think she took some lobelia and some composition powder. The latter is a composition of bayberries, ginger, cloves, cinnamon, and a little Cayenne pepper. It is a composition to stimulate the circulation and to aid perspiration. It is not very material as to the quantities of each. I took no part in this matter—it is all my wife's management. I believe my wife is superior to myself. I have a very extensive practice. I buy the herbs, and prepare the medicines myself. I make my own tinctures and salves. I don't practise midwifery. I was a long time in the service of 'Dr. Skelton, of Leeds. I don't go anywhere, except they almost compel me to go. I don't charge for medicine. It is all gratuitous. I did not charge anything to Mrs. Barraclough. I never charge in a case like this. If persons come for herbs I sell them. I don't know of my own knowledge what my wife took, except the herbs which I gave her. She has told me she took lobelia and a little composition."

Mrs. Airey also gave evidence, and, with becoming modesty, disclaimed the compliments paid to her by her husband, stating that "he understood it better than she did." She further said: "I gave the deceased about half a teaspoonful of lobelia; and gave her nearly the whole of the composition in small doses in the herb tea. I first gave the deceased an injection; and then the herb tea. I then put a warm brick to her feet, and one to each side, to get her into a perspiration."

Dr. David Kay made a *post mortem* examination of the body, from which he arrived at the conclusion that the patient died from congestion of the lungs and brain, most probably produced by the action of some poisonous substance taken before death.

The jury returned a verdict "that the deceased died from congestion of the lungs and the vessels of the brain, but whether this was caused by the improper administration of a quantity of lobelia by a self-appointed vendor of medicine does not fully appear;" accompanying the verdict with a request that the coroner would administer a suitable reprimand to Airey for the improper part he had taken in dealing with such a case.

The coroner accordingly called Airey, and administered to him a severe rebuke—telling him that he was an ignorant quack, whose knowledge of medicine was of the meanest kind; that his

conduct was reprehensible in having by false representations sought to remove the responsibility in this case from himself to his wife; and that this subterfuge, if the result of the *post mortem* examination had been such as to satisfy the jury that death had been caused by the improper administration of lobelia, would not have saved him from a verdict of manslaughter.

We are informed in the same paper, that "Mr. Airey was a woolcomber a few years ago, and now appeared as a well attired young man, with a massive gold chain about his neck and waist-coat. His 'wife' is an Irishwoman, and put 'her mark' to her deposition. According to Mr. Airey's account, as stated above, he has a flourishing 'practice'! We understand he was once in trouble in a matter of bigamy!"

THE HONOUR OF KNIGHTHOOD has been conferred on Dr. John Forbes, Physician Extraordinary to Her Majesty's Household, and President of the Metropolitan Counties Branch of the Provincial Medical and Surgical Association: and on Dr. James L. Bardsley, Consulting Physician to the Royal Infirmary, Manchester.

ROYAL COLLEGE OF SURGEONS:—PASS LISTS. MEMBERS admitted at the meeting of the Court of Examiners on July 1st:—Samuel Argent, Hinckley, Leicestershire; Thomas Chaplin, Lewes, Sussex; Peter Clark, Kirkconnell, Dumfries; Ephraim Matthews Cridge, Stoke, near Devonport; John Henry Gould, Broad Street, Golden Square; John Halliday, Wakefield, Yorkshire; William Hall Ryott, Thirsk, Yorkshire; Arthur Henry Sankey, Dover; Richard Burford Seale, Bridport, Dorset; Northcote William Spicer, Chard, Somerset; William Turner, Lancaster.

July 4th:—Charles Dunn, Scarborough, Yorkshire; James Thomas Fraser, Southampton; Henry Leach, Trinity Square, Southwark; Evan Llewellyn, Mount Place, Whitechapel Road; Thomas Alexander Moore, Preston, Lancashire; John Blake-more Phipps, Ipswich, Suffolk; John Bye Silver, West Wrating, Cambridgeshire; Alexander Packington Tomkins, Hon. East India Company's Service; William Edward Monckton Watts, Battle, Sussex.

July 8th:—James Collinge, Manchester; James Eyres Coward, Tiverton, Devon; Edward James, Exeter; John Ingham Fearley Marshall, York; Frederick Northover, North Brixton; Francis M'Manus Russell, Quebec; Thomas Robert Williams, Wincanton, Somerset; Luke Young, London.

July 11th:—Arthur Dupuy, Mauritius; John Hume, North Shields; Frederick Bellingham Swann, Weedon; Thomas Tomlinson, Maldon, Essex; Edmund Waller, Chesterfield, Derbyshire; William Philip Whitcombe, Wolverhampton.

July 15th:—William Falconar Clark, Cunningham Place, St. John's Wood; Matthew Corner, Whithy, Yorkshire; George Jules Gillam, North Leigh, Oxfordshire; Francis Gould, Dublin; John Heys, Liverpool; Thomas Lewis Grouger, Llandilo, Carmarthenshire; Arthur Edwin Temple Longhurst, Kirkby Mallory, Leicestershire; Samuel Alexander Patterson, Downham Market, Norfolk; John Sutton, Keyworth, Leicestershire; William Wright, Lincoln.

APPOINTMENTS.

[*An asterisk is prefixed to the names of Members of the Association.]

*BROADBENT, Edward FARR, Esq., elected Surgeon to the Lincoln County Hospital, on the 29th ultimo.
DAMPIER, N. J., Esq., elected Surgeon to the Farringdon General Dispensary and Lying-in Charity.
MILES, Charles, Esq., elected Surgeon to the Farringdon General Dispensary and Lying-in Charity.

OBITUARY.

[*An asterisk is prefixed to the names of those who at the time of their decease were Members of the Association.]

TAIT, Dalhousie, M.D., only surviving son of the late Captain Tait, R.N. of Pirn, at Calcutta, on May 20.

BOOK RECEIVED.

[*An asterisk is prefixed to the names of Members of the Association.]

ASSOCIATION MEDICAL JOURNAL.

EDITED BY JOHN ROSE CORMACK, M.D.

No. XXXIII.

LONDON: FRIDAY EVENING, AUGUST 19, 1853.

NEW SERIES.

August 5th, 1853.

In consequence of the One and Sixpence Duty on Advertisements having been repealed, the following scale will be adopted for all Advertisements ordered to be inserted after this date:—

For three lines and under	-	-	-	£0	2	6
For every additional line	-	-	-	-	0	6
For half-a-column	-	-	-	-	1	10
For a whole column	-	-	-	-	2	15
For a page	-	-	-	-	5	5

A line contains ten words, so that any one can calculate the cost of an Advertisement.

Advertisements ought to be delivered at the office on the Wednesday preceding publication, and paid for at the same time.

Post-Office orders are to be made payable to THOMAS JOHN HONEYMAN, 37, Great Queen Street, Lincoln's Inn Fields, London.

THE ASSOCIATION JOURNAL will, like the old series, consist of ANNUAL VOLUMES. The convenience of a single index for the year is obvious; and the expense of binding is less than if the year was divided into two volumes. The Association year is from January 1st to December 31st; and for that reason it is desirable that the Journal should represent the same period of time.

THE SWANSEA MEETING.

TO-DAY our columns contain a long and circumstantial report of the Twenty-first Anniversary of the Provincial Medical and Surgical Association. Within the brief space of two days many important questions were considered, both in the departments of Association polity, and medical science. Much, we admit, was also left undone: but we are confident that upon the whole there was as great an amount of work accomplished as could have been performed by any body of men, of variously constituted minds, in an equal space of time.

The *Finances* of the Association occupied a large share of attention: but, had time permitted, they might with advantage have engaged still farther the consideration of members. While it is gratifying to be told in the Council Report "that the list of members is more perfect than it has heretofore been, and that fewer members are in arrear", it is most unpleasant to find, from the next clause of the same sentence, that "still £1093 are owing to the Association for subscriptions". As we are not informed how much of this sum is owing for the current, and how much for previous years, we cannot even guess at the proportion of this amount which is likely to be received; but, taking the most favourable view of the case, it is evident that £1,093 due to the Association on the 1st of January last (the day on which the Association year commences) had not been received by the treasurer on the 31st of July. This fact alone demonstrates the necessity of a more thorough organisation of our members under local discipline. Having no clue to the value of this large amount of arrears, it would be absurd for us to say what we think it is worth; but without entering the regions of speculation we may aver that, if every defaulter who reads these lines takes shame to himself, and at once remits his one, two, or three guineas to Mr. Sheppard, at Worcester, or to

some other authorised local receiver, we shall have a cleaner and more creditable balance sheet to greet us at Manchester.

At Oxford last year, the amount of arrears was stated to be £1900; so that we have added to our arrears £93. But there is a more cheerful contrast between the amount of subscriptions announced at Oxford as received during the year 1851-52, and the amount of subscriptions announced at Swansea as received during the succeeding twelve months. The year's income from subscriptions was reported at Oxford as £1,365:11:11; whereas at Swansea we have a return of £1,785:5:5—an increase of £419:13:6. At Oxford, the members on the roll were 1,629. Of this number 200 were, at January 1st of this year, struck off as persons who were either dead, or defaulters, or who had resigned: yet at Swansea our year's increase, both in numbers and in income from subscriptions, is more than twice as much as our surrender of unprofitable names.

So much will be found regarding the finances in subsequent columns of this number, that we shall for the present leave this subject, after stating the law of the Association with reference to arrears. The twenty-fourth law directs that THE JOURNAL SHALL BE WITHHELD FROM MEMBERS WHO ARE TWELVE MONTHS IN ARREAR: and, after the discussion which took place at Swansea, the Secretary cannot be expected to continue past forbearance towards those who have so much abused his kindness. Dr. Tunstall was perhaps substantially correct, when he spoke of members having received the Journal gratuitously for three years; but when this has occurred, it has only been through indulgence, and we may add, through a species of indulgence never again likely to be allowed. At the request of the Secretary, we most earnestly call attention to a law which was made at the Hull meeting in 1850; and which for the future is to be rigorously enforced. It is as follows:

"If any member's subscription remain unpaid twelve months after it shall have become due, the *Medical Journal*, and other publications of the Society, shall be withheld from such member till his arrears be paid; and when any member has been in arrears of subscription for the space of three years, application shall be made for the same by the General Secretary, and, if the arrears be not paid in *three months*, the name of that member shall be omitted from the list of subscribers; but this omission shall not be deemed, either in honour or equity, as releasing any gentleman from his subscriptions owing during his membership."

It was gratifying to find, that notwithstanding the great expense which has attended the as yet unavailing efforts of the Association in the cause of *Medical Reform*, all were of one mind as to the propriety, nay, the necessity of continuing the struggle with unabated zeal under the auspices of the same committee who have hitherto so ably conducted this business. Last year £200 was voted to the Reform Committee from the funds of the Association: this year, the Committee is to be thrown upon the private generosity of the profession. A subscription has already been commenced in a very spirited manner, regarding which we shall be able

to speak upon a subsequent occasion more in detail than at present.

The idea seems to have gone abroad very widely that the *Benevolent Fund of the Association* and the Benevolent College have exactly the same objects in view, and are in fact rivals in precisely the same field of philanthropy. The distinctive characters of the two institutions have been often pointed out both by Mr. Newnham and Mr. Propert; but they have, nevertheless, been generally regarded as almost identical. We trust that the recognition of these admirable charities by the Association may be the means of extending their usefulness; and that in future, donors will perceive that by contributing to the College they are not giving to the relief of those urgent cases of distress which it is the province of the Fund to succour; and that on the other hand, the cases which the College proposes to help never can be taken up by the Fund. The College and the Fund are not rivals: they are Sisters of Mercy, each having her own peculiar sphere of piety. We trust, therefore, that those who from a misapprehension transferred their subscriptions from the Fund to the College will, in future, recognise the claims of both institutions.

The debate on *Medical Ethics* may be regarded as the most prominent feature of the meeting. The task which has been assigned to the committee is not the less necessary, that it is both difficult and delicate. Possibly we may not receive at Manchester a medico-ethical code in a form quite ready for adoption; but we may at least hope for a valuable contribution towards this hitherto almost unwritten chapter of our laws. Excepting the 22nd law in the old sheet, and the laws regarding irregular practitioners, which were adopted at Oxford on the report of the Brighton Committee, the Association has not, as yet, formed any ethical rules. This opprobrium need not long attach to our body; for if the secretaries of the Branches collect and digest the opinions of their constituents, the report of the Ethical Committee will carry with it so much weight as necessarily to command approval and adoption.

While it is matter of congratulation that so much business was so well accomplished, it cannot but be deeply regretted that the important question of a *Revision of the Laws* could not be entered upon. The discussion would have naturally afforded an opportunity of shewing how eager the Association was to respond to the fraternal salutations from the other side of the channel. It does, indeed, deeply grieve us to think that a whole year must be lost before the PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION can have an opportunity of so modifying its rules, as to reciprocate with its Irish brethren the privileges of an *ad eundem* membership. Then, again, considering the great accession of members which we have recently had from Scotland, it was, we know, expected by our friends on the other side of the Tweed, that such an alteration would be shadowed forth as would enable a committee to state the best method of giving to our Scottish colleagues the position and the power in our councils, to which they are entitled. Considering that the Association has now attained its majority, the occasion was looked forward to as suitable for mooted the question of the members being entrusted, through duly chosen representatives, with the management of their own affairs.

These deeply important and vital questions, as well as others connected with finance, ought to have been con-

sidered; but they could not have been adequately expounded, or patiently listened to, during the brief space which remained between a protracted meeting and an appointed feast. Again we say, that we regret that these subjects were not unfolded at the meeting, as we feel that questions of Association polity, about which there is notoriously a diversity of sentiment, ought but sparingly to occupy the editorial pen.

The *Arrangement of the Business* at future anniversary meetings is evidently a subject of the greatest practical importance. Owing to the admirable management of Dr. Bird, a much greater amount of business was transacted than could under ordinary circumstances have been anticipated; but still, as we have already said, some of the most important discussions which could have engaged the meeting were left unattended to for want of time. Perhaps we may be allowed to suggest, that a good deal of time might at future anniversaries be saved by making one or both of the addresses form part of the proceedings of the evening of the first day—a plan which was adopted with great success at Worcester in 1849. Such a plan would effect a clear gain of two hours. A further relief might be obtained, were the authors of communications to be restricted to a specified amount of time. In this way, the forenoons might be devoted to business, and the evening of the first day to science. The opportunities of listening to and reading scientific communications are abundant, both in town and country; but it is only once in twelve months that the profession is convened to discuss questions of medical polity and internal discipline. It therefore behoves the Association to turn this annual opportunity to the best possible account.

The news that Her Majesty had conferred the honour of knighthood upon Dr. John Forbes and Dr. J. L. Bardsley reached Swansea during the first day's proceedings, and was hailed with universal satisfaction. It was felt that inasmuch as these eminent men are two of our oldest and most distinguished members, an honour had been conferred not only on them, but upon the Association itself, as when Sir Charles Hastings was knighted some years ago, and as when he, along with Sir John Forbes and Dr. Conolly, last year received the honorary degree of D.C.L. from the University of Oxford. All honour to the Queen for uniting with the Association and the whole medical profession in delighting to honour our illustrious colleagues—Sir Charles Hastings, Sir John Forbes, and Sir James Lomax Bardsley.

VACCINATION BILL.

THE Vaccination Bill has passed through Parliament, and is ready to receive the Royal assent. In the opinion of the learned, and noble, and right reverend lords, who constitute the Upper House, and the merchants, barristers, naval officers, military officers, and country squires, who represent the people in the House of Commons, the medical profession as a body is either too paltry or too powerless as a political party to be worthy of being courteously consulted. The bill has been very much improved since we first assailed it in these columns; but the way in which it has been thrust upon the profession is most reprehensible. Additional evidence, however, has been given that there can be neither safety to the public nor justice to the profession, till several medical men have seats in Parliament.

ORIGINAL COMMUNICATIONS.

CASES OF CONGENITAL MALFORMATION OF THE RECTUM AND VAGINA.

By GEORGE MALLETT, Esq.

CASE I. IMPERFORATE ANUS: RECTO-VAGINAL FISTULA: OPERATION SUCCESSFULLY PERFORMED. Mary I—n, aged two years and a half, apparently a healthy and well-formed girl, was brought to me, her parents being desirous to ascertain if anything could be done to relieve a disgusting defect, which had existed from birth. They stated that there was no anus, and that she had passed all her feces through the vagina. An examination disclosed neither aperture nor depression where the anus should have been. Upon making further inquiry, I found that every second or third day she became restless and uneasy, and that she endeavoured to make them understand that she suffered pain in the lower or pelvic region. This state generally continued for an hour or two, when it was relieved by a copious discharge of feculent matter from the vagina. The feces were rarely liquid, their consistence being firm and about one-twelfth of an inch in diameter, or about the thickness of ordinary packthread. These deposits had a very curious appearance, the motions being at least two or three yards in length, and much resembling heaps of worms. After each evacuation she became perfectly well for two or three days, and seemed to enjoy excellent health and spirits.

Upon a careful examination of the vagina by means of a probe, I found at its further extremity a canal, evidently communicating with the rectum; and from the horizontal direction of the probe, I inferred that the communication was very near to the normal termination of the guts, and that probably the only defect was a closure of the natural outlet. I recommended an operation; and was then informed that several medical men had seen her previously, and that they had advised that the case should not be interfered with, as an operation might be dangerous and the result uncertain. Notwithstanding this, I still gave it as my opinion that the operation, if carefully performed, would not be attended with much danger; and that the result would most probably be favourable. In consequence the parents resolved that the child should be submitted to the operation, which was performed a few days after.

The little patient was placed near the edge of a table, and the thighs were drawn aside and elevated; in fact, she was placed nearly in the position for the performance of lithotomy. The probe was then introduced through the vagina into the rectum, and held steadily there by an assistant. There being no depression to indicate the natural situation of the anus, the integuments were divided by a scalpel, as near as we could judge would be the right place. The incision was carried about three-fourths of an inch in depth, when the end of the probe was felt, and another touch of the knife laid the bowel freely open. Almost immediately, a copious and rather firm motion was passed, apparently without much pain. Scarcely any blood was lost, either during or after the operation. The wound having been cleaned, a moderately sized candle, a bougie not being in readiness, was pushed in and allowed to remain.

On the following day, I found all going on well. The candle had been forced from the wound soon after my departure, and was followed by some more consistent feculent matter. A bougie was then introduced, lest the orifice should become too much contracted. On my next visit, I found that the bougie had shared the fate of the candle, and also that it had been followed by an evacuation.

It would be tedious and unnecessary to detail the further progress of the case: it will be sufficient to say, that there was but little trouble, and no anxiety, respecting its progress; and that, in about a month, the cure was complete. The recto-vaginal canal also became obliterated, no feces having passed by that channel since the operation; and, at

my last visit, I tried to introduce the probe as before, but failed in the attempt.

I lost sight of the patient for nearly two years; and at the expiration of that time I had an opportunity of inspecting the parts. I found all as it should be, excepting that the anus was rather more retracted and puckered than usual. There had been no difficulty in passing the motions *per viam naturalem*, if I may be allowed to apply such a term to a passage artificially made. There was also the power to retain the motions; from which I infer that the sphincter ani muscle had been formed in its natural situation, and that the scalpel had passed through it.

CASE II. OCCLUSION OF VAGINA. OPERATION: CURE. I was requested to examine Sarah T—, aged five years, a healthy looking girl, who had had some defect from birth in the genital organs. The only opening into them was a very small orifice in the upper portion of the external labia, scarcely large enough to admit a crow-quill, without being somewhat dilated by it. Through this opening the urine had always been expelled in a small stream. A probe was introduced, which passing downwards and backwards seemed to enter into a wider space, which I concluded to be the vagina. I recommended that the labia externa should be divided; and the parents consenting, a director was immediately pushed inwards and downwards, and a free incision made with a bistoury. An accurate examination of the interior, displayed by the incision, could not detect any deviation from the natural form and condition of the parts. I had some trouble in keeping the divided edges of the wound from reuniting, and in preventing too great a degree of contraction. The operation was, however, by the unremitting use of sponge tents, at last permanently successful.

Bolton-le-Moors, Lancashire, August 1853.

DEATH FROM THE BITE OF A CAT.

By GEORGE ALLEN, Esq.

A REPORT of the following case has appeared in the local papers. I had intended to bring the subject before the annual meeting of the Bath and Bristol Branch, but was prevented by professional duties. I now publish the case, as a general reply to the numerous letters which I have received on the subject.

CASE. On June 6th, 1853, I was called to see Richard Hunt, who was stated to have been bitten by a cat eight days previously. The statement given to me was, that the cat had been ill for some days, that it had refused food, was very thin, and had a noise in the throat resembling that of croup, with hurried laborious breathing. A lad had taken the cat by the tail for the purpose of killing it. Richard Hunt, passing at the time, seized it by the loins, when the cat bit the joint of his left thumb, which became very painful, and before night the hand and arm were swollen and inflamed. On the following morning, bladders of water had formed round the wound, hand, and arm, but he refused to have medical aid. Linseed-meal poultices and lotions had been applied to the hand, and some Epsom salts had been given to him, and to all appearance he was going on well, until the third night, when he got inebriated. After this period he did not complain of pain in the thumb; the swelling of the hand and arm had subsided; but shivering came on with pains all over him, accompanied by great difficulty of breathing. No medical aid was sought for eight days after the accident.

When I first saw him, on the morning of the sixth of June, I found him excessively nervous and dejected. The eyes were sunken, the breathing short, the pulse feeble. Upon examining the thumb, and removing the thickened corrugated skin, a copious ichorous discharge followed, the surface below having a livid appearance; there was very little sensibility to touch.

I ordered the arm to be kept in a sling; brandy and barm in linseed-meal poultices to be applied, and removed

every three hours; and brandy in gruel and arrow-root, and strong beef-tea, to be given. The treatment consisted of ammonia, camphor, and opium, administered at intervals of three hours.

June 7th. He had some refreshing sleep during the night. His countenance was this morning more cheerful. The breathing was not so difficult; the pulse was firmer. The wound was looking healthier. He was directed to continue the same treatment in every respect.

June 8th. He passed a comfortable night. The wound was discharging pus; and he had no pain in or about the surrounding parts. Pulse 80, full but soft. He was down stairs. The same treatment was continued.

June 9th. He was in every respect as yesterday. The wound was looking healthy. He was ordered to continue the same treatment.

June 10th. He was in every respect as yesterday.

June 11th. This morning he was not out of bed. He complained of being chilly. The breathing was rather short. The right shoulder, particularly at the back part, was very intolerant of pressure; in fact, the whole of the right side and epigastric region could not be pressed upon without considerable pain being given to the patient. No pain was experienced on percussion or other manipulation about the spinal column, chest, or cardiac region. The wound was discharging healthy pus. The pulse was stationary at 80. He was ordered to have mustard poultices applied to the side and epigastric region. Powders, with sesquicarbonate of ammonia, hydrargyrum cum creta, and Dover's powder, were given every three or four hours.

June 12th. He had had some refreshing sleep during the night. The breathing was not so difficult. He expressed himself as being much relieved. He did not wish to get up, stating, that when he attempted to get out of bed, the pain became most violent at the right shoulder-blade. The wound was discharging healthy pus; but there was no appearance of granulation.

June 13th. He was in every respect as yesterday.

June 14th. He passed a restless night. The breathing was very short; the head hot and painful; the eyes intolerant of strong light; the pulse 96, small and thready. The hair was ordered to be removed, and the head sponged with cold vinegar and water. Mustard sinapisms were applied to the feet, and a blister to the chest. The room was ordered to be darkened. Saline effervescing medicine with opium was prescribed.

In the evening I found him very much relieved. The head was cooler; and light was borne with less distress. Pulse 90.

June 15th. He had had a restless night, but no delirium. The head and skin were hot; the pulse 98; the breathing short; the bowels irritable; frequent evacuations of biliary matter occurred; he had much thirst; the urine was turbid. The saline effervescing medicine was discontinued, and a saline mixture with opium and tragacanth mucilage substituted; and compound chalk mixture was ordered to be given occasionally. In the evening I found him rather better. The bowels were not so much relaxed.

June 16th. He had had some sleep during the night. The head and skin were not so hot; the bowels not much relaxed; the wound was looking healthy; pulse 90.

June 17th. I was hastily summoned to see him. He had been delirious, and had sprung out of bed; but was now lying perfectly calm. Vision was apparently gone; the breathing was stertorous; the pulse 130. In this state he continued until the morning of the 20th June, when he died without a struggle.

Decomposition set in so rapidly (favoured no doubt by the then hot and humid state of the atmosphere), that I had no opportunity of obtaining a *post mortem* examination.

Two persons who had been in attendance on the deceased have since been taken ill.

The first was a young married woman, at whose house the deceased lodged, and who had constantly attended upon him and dressed his wound. She was seized, on the morning of his decease, with "synocha" in its most aggravated

form, and had one symptom connected with the case of the deceased, by which I was most forcibly struck, viz. the same intolerance to being touched upon the right shoulder blade, whilst other parts of the body might be handled freely. Copious venesection, mercurial purges, with calomel, antimony, and opium, and saline diaphoretic medicine, cut short the attack; and in five days she became convalescent.

The second, a neighbour's servant (who had assisted in removing the bed-clothes), was seized with faintness, headache and vomiting; but nothing further occurred.

Lodway Villa, St. George's, Somerset, Aug. 3rd, 1853.

CASE OF DOUBTFUL SEX.

By R. M. MANN, Esq.

Miss H., aged 28, was brought to me by her mother for examination, on July 18th, 1853. She had never been examined previously by a medical man, or by any other person. It was stated that her chief reason for applying to me was, that she had had an offer of marriage, and was anxious to know if she could enter the matrimonial state.

On examination, I found to all appearance a perfect penis, from an inch and a half to two inches in length, with distinct glans, corona glandis, and præputium, with the ordinary white secretion so commonly observed between this gland and the prepuce. The orifice of the urethra was on the under part of the glans, and was capable of admitting an ordinary sized goose quill. There was a distinct scrotum, but without testes; and this part, as well as the pubes, was covered with hair in the usual way. The mammae and nipples were those of a female. No growth of hair had taken place on the face or chin; but the voice was decidedly masculine. She had menstruated regularly since sixteen years of age, for about three days at a time, and had pain in her side at that period. The discharge came through the urinal aperture (as there was no other), which had doubtless a communication by a rudimentary vagina with an uterus. She stated that she had experienced sexual desire. When she was an infant, the nurse, though doubtful as to the real nature of the case, advised female costume, which has been adopted ever since.

The above case appears to resemble in some respects that which is reported by Dr. Schneider, and detailed in the twenty-first volume of the *Dict. des Sciences Médicales*, p. 97.

Manchester, August 13, 1853.

BIBLIOGRAPHICAL NOTICES.

THE SOPHISTRY OF EMPIRICISM. 8vo., pp. 84. London: 1853.

THIS able work gives an interesting and instructive account of some of the most famous forms of modern quackery, such as Mesmerism, homœopathy, hydropathy, and bone-setting. We have also some excellent remarks upon the claims of scientific medicine, and on the circumstances which favour the production of empiricism.

The *herbalists* are thus depicted:—

"Their outward appearance is intended to represent something of the practical gardener; but the impudent effrontery of the itinerant showman is stamped on the forehead. Their eloquence is fluent and exalted, and they can descend with abundant favour on the wisdom of the Creator in providing such a multitude of herbs for the benefit of the human race, who, without their aid, would be hastening fast to an untimely grave. On the other hand, the graphic tongue of such a sage can describe in glowing colours the destructive nature of minerals, with their necessary tendency to precipitate patients into the very habitations from which they were dug; and contrast their direful influences with the vivifying power of vegetables, which cause man to flourish like the lily of the valley, and mount into the heavens like the cedars of Lebanon. These worthies also find

it advantageous to exhibit specimens of their wares, consisting of

"Horehound, sage, mint, and thyme,
With hyssop, famed in every clime.

A few of this fraternity also deal, to a certain extent, with the herb named *savin*, and profess a mysterious knowledge of its powers in preventing those results which might prove serious to the reputation of a fair name." (p. 76.)

Bonesetters are thus described:—

"They are a little different from the herb doctor, being apparently more akin to the carnivorous than the herbivorous race of animals; and they often merit the title of 'whiskerandos' in a superlative degree, with a kind of braggadocio ferocity of countenance, a swaggering gait, and large superior extremities, which serve as indices of the Herculean power required in their important occupation. Their knowledge of human osteology has generally been derived from their scientific researches into the diseases and accidents of the domesticated quadrupeds; hence, professional accuracy and sound treatment are naturally to be expected from so excellent an analogy. This is a calling which in some instances has proved hereditary, descending from father to son, and even to a third generation; and we have heard of a regular practitioner who acquired much local fame in the treatment of fractures and dislocations, because his father was a celebrated manipulator in bone-setting. This brotherhood have a wonderful facility in discovering dislocations that do not exist, and seldom fail to imitate, by a sleight-of-hand movement of their own fingers, the characteristic snap which is often felt and heard when bones are put into their natural situation." (p. 77.)

Various quacks, great and small, are alluded to in groups and singly. In speaking of the northern metropolis, the case of the pseudo-physician who has drained the cup of degradation to its dregs is thus handled. The author evidently concurs with us in thinking that the profession of pathology in a University pulpit, and the practice of homœopathy among his patients, involves an amount of inconsistency both in creed and conduct, which can hardly be estimated.

"When the heresy is one that is merely *outré* or somewhat extravagant, the case is sufficiently bad; but if it be one that carries absurdity in its very front, and outrages all former philosophy and experience, its defenders ought either to walk out from the academic halls with a clean conscience, or be ejected into that *terra incognita* which they have discovered, and where they might reign triumphant among their own chaotic phantoms. But the potent talisman, the *aut ritam aut culpam*, at a touch of their magic wands, immediately springs up to their aid, from its generally undisturbed repository; and the transcendent philosophers sneak into its nook with instinctive sagacity. O ye lawyers of the northern metropolis, ever distinguished for your learning, acuteness, and ingenuity, can you not transmute this plausible little word *culpa* into something tangible, for it often slips through your fingers as if it were a mere nonentity? Is the word so indefinite that it cannot include absurdities in doctrine, impossibilities in belief, and a glaring violation of a presumed contract, in the discharge of most important duties? If the law of the land be paralytic, from extreme age or other causes, can the great law of equity thunder any of its wholesome anathemas against such delinquencies? Ye shades of Black, Cullen, Monro, Playfair, and Leslie, and ye who represent in greatness these illustrious names, which have shed such imperishable lustre upon your native land, can you contemplate with anything but scorn the men who have trampled on your high philosophy, and placed in substitution of your unerring demonstrations, visions of the brain, and fantastic atoms which can only be measured by the imagination?" (pp. 84-5.)

These extracts will convey an idea of the author's style. The whole work is well deserving of perusal, and we are sure that its circulation among the public is calculated to remove many mistaken ideas as to the manner in which medical men regard empiricism and its disastrous consequences.

ESSAYS. By H. S. BELCOMBE, M.D. 12mo., pp. 52. York: 1853.

In this pamphlet, we have three well written essays on Sleep, Dreams, and Sympathy. From the Essay on Dreams, we cull the following passage:—

"From the argument employed, I should desire to draw these deductions:

"1. Dreams proceed from the partial exercise of the faculties of the mind, and of the senses; the judgment, generally, no longer controlling them.

"An entire sleep is free from dreams, because all the faculties, and the senses, are then in repose, and, indeed, it is seldom that the first sleep in good health is attended by dreams; it is only towards morning, when some of the faculties awaken, that dreaming commences.

"2. Whatever may be the extravagance or incongruousness of the ideas presented to us, they are but the remembrances, or combination of remembrances. A French philosopher calls them the memory of the senses. Locke, more tersely, says, 'The dreams of sleeping men are, as I take it, all made up of the waking man's ideas, though for the most part oddly put together.' Perhaps their strangeness simply consists in the unaccustomed association of such ideas, because in sleep we are freed from all the laws of chronology, of relation, and of time. If any person will analyse his dream, he will find that he never has dreamt, and never can dream, of anything entirely unknown to him.

"We might also, perhaps, not be so much astonished at the singularity of our dreams, if we only reflected that, when awake, there are four powers that mutually watch over and rectify each other, viz., the sight, the hearing, the touch, and the memory; whereas in sleep each sense is abandoned, if I may so express myself, to its own resources.

"I think I am also justified in drawing these two conclusions respecting dreams and the utility of their investigations. They are useful in affording prognostics in various diseases.

"At the commencement of fevers in particular, sudden fright, the waking up in surprise, a convulsive anxiety during the dream, denotes that the disease will be long, perhaps complicated with some organic affection. These kinds of dreams also often precede and announce delirium.

"When we hear noises, explosions, tumultuous cries, it is more than probable that our dreams partake of a delirious and morbid nature, or of sensorial or intellectual hallucinations, in which the mind is actually diseased, and the perceptions become erroneous. When these hallucinations prevail after sleep, mania may be apprehended.

"In females of a nervous or of a sanguine temperament, when in a state of disease, the dreams are generally of a very painful character, the subjects being frequently murders, or some tragical events, where bloody and red coloured objects are seen.

"The morbid states of the thoracic and abdominal viscera are very much indicated by the dreams; even in their early state, when attention has scarcely been called to them, they will afford some diagnostic information. Thus, under such circumstances, dreams frequently occur in the first sleep, which are to be regarded as a bad omen. Also in dropsy of the chest, hardly has the patient dropped asleep than he considers himself placed in the most painful situations, perhaps on the point of being suffocated in some mode or other, without the power of opposing any resistance.

"In the diseases of the heart, or of the great vessels, the dreams are almost always short, and followed by sudden anxious awaking; the subjects are almost always painful—a precipice, or inclosed in vaults, often sudden death under dreadful circumstances.

"Gastric diseases are attended with dreams of hideous phantoms, horrid faces; and in these diseases, as well as in hypochondriacism and hysteria, there will be every shade of gloomy fancy, from a slightly painful oppressive dream, perhaps of a pigeon pie with live pigeons ready to fly out of the stomach, up to the most complete nightmare."

ELECTRICITY AND GALVANISM IN THE TREATMENT OF CANCEROUS, NERVOUS, RHEUMATIC, AND OTHER AFFECTIONS. By R. M. LAWRENCE, M.D. pp. 101. London: 1853.

THE Leyden jar "is not applicable to medical purposes, because, by bringing large quantities of electric fluid of great intensity at once into action, it produces in the human body concussions of too violent, and consequently injurious a nature." (p. 5). Yet, at page 31, the author, on the authority of Dr. Golding Bird, very properly recommends electricity as a direct and more valuable emmenagogue; and the form in which it was applied by that physician was by

passing these "violent concussions" through the pelvis. How Dr. Lawrance could advocate Dr. Bird's practice at page 31, after characterising electric shocks as perilous at page 5, is not very obvious.

At p. 10, a figure is given of one of the electro-magnetic machines, consisting of a single wire coiled round a bundle of iron wire, in the usual manner. After, in the preceding page, giving a serious caution against the use of an induced secondary current, he states the value of the single wire apparatus to consist in its "deriving its electricity from the battery, the current being sent through one coil of wire, in order to give it sufficient continuity to overcome the resistance which it experiences in passing through the body." Surely Dr. Lawrance must be aware that the shock produced by this apparatus is the result of an *indirect current*, and not of the battery current at all. The idea that a current of electricity is made more intense by causing it to traverse a long conductor, is quite unworthy of any writer on such subjects. Every one must be aware that every conductor, however good, offers an obstruction to the passage of a current. We had thought that the luminous researches of Dr. Faraday were sufficiently known to prevent any one being ignorant of the fact that the *apparent* increase of intensity of a current, on traversing a coil of wire, arose from the excitation of an indirect current, the result of the disturbance of the electric equilibrium of the wire.

Chapter II commences with a remark which cannot escape censure. The author states that "the *description (!)* he has given of electro-magnetic coils evidences how little attention has been paid to the subject. In fact, this agent has been employed in the treatment of disease merely with a vague notion of its power to remove the sufferings of the patient, and without a knowledge of those laws which guide its action, or any definite idea of the results to be expected from its application. No wonder that a remedy conducted in such blind ignorance of its operation should fail, and disappointment ensue to those who had resorted to it, perhaps when all other means had been tried in vain." (p. 14.)

This extract at once shows the character of the book: remarks of this kind cannot be justified. When an author can level the charge of "blind ignorance" at other practitioners of far higher standing and larger experience, he places himself almost beyond the pale of scientific criticism. He cannot be unacquainted with the lectures delivered by Dr. Golding Bird before the College of Physicians, and since published; he cannot, surely, be ignorant of the papers published in Guy's reports by Dr. Addison and Dr. Bird, and more lately by Dr. Gull. If the author of this remarkable book has not studied these contributions to our knowledge, he should hesitate before levelling the charge of "blind ignorance" at others. If he is acquainted with them, Dr. Lawrance is bound to justify such an accusation, to escape the judgment the profession must form of his thus presuming to wield the censor's rod.

With regard to the therapeutical application of electricity, there is not one remark which is new, there is not a single contribution to our knowledge in the whole volume. The sketch given of the reputed value of electricity in the treatment of different diseases is most meagre and imperfect. Indeed, so much so, that a person unacquainted with the application of electricity as a remedy could not, by any possibility, learn from its perusal the mode of applying it.

It is really difficult to conceive what could prompt the sending forth of such a book, one which bears evidence of the fact that its author has not very clear views of the *modus agendi* of electricity. As an example among many, Dr. Lawrance states that in certain conditions, the "free electricity in the nerves should be increased", p. 29; and under this head he gives an account of the application of electricity to the uterus in the mode suggested by Dr. Radford, to produce parturient action of that organ in cases of hæmorrhage during labour, and ends with an extract from Dr. G. Bird's lectures on the subject. He afterwards speaks of cases in which the "free electricity in the nerves should be decreased", p. 50; and under this head he requotes Dr. Radford's suggestions for the employment of electricity in in-

ducing uterine action, and gives an account of the cases of Mr. Cleveland and Dr. Dempsey, in which those gentlemen succeeded in inducing labour by passing electric currents through the uterus.

How electricity could act in one set of cases by *increasing*, and in another precisely similar one by *decreasing*, the free electricity in the nerves, must be left for wiser heads than ours to explain.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THURSDAY, JUNE 7, 1853.

JAMES COPLAND, M.D., F.R.S., President, in the Chair.

A CASE OF PERFORATING ULCER OF THE ŒSOPHAGUS, WHICH CAUSED DEATH BY PENETRATING THE AORTA. BY W. H. FLOWER, ESQ. (COMMUNICATED BY CAMPBELL DE MORGAN, ESQ.)

A painter, aged 51, had, an hour previously, suffered from profuse hæmorrhage from the mouth, the blood being bright and frothy; syncope supervened, in which state he was brought to the hospital. He was tall, well made, and muscular; but the countenance was death-like, the pulse imperceptible, and there was absence of consciousness. About a week previously, he had complained of a deep-seated pain at the top of the sternum, shooting to the spine. He was placed in bed, ice put into the mouth, and large doses of acetate of lead were administered. Slight reaction ensued. The next morning, at half-past nine, the pulse was 100, firm, steady, though small. On auscultation, free inspiration was heard in every part of the chest, except the upper lobe of the left lung, where the respiratory murmur was deficient; there was increased vocal resonance, and some dullness on percussion in this region. At 10 A.M. a fresh attack of hæmorrhage supervened, which proved fatal.

On examining the body, fifty-three hours after death, a few old adhesions were found at the apices of both lungs, with a few crube tubercles in the upper lobe of the left: the remaining portion of the lungs was much blanched. The heart was loaded with fat, but otherwise healthy; no coagula in any of the cavities. The stomach contained a clot of blood, which formed a complete cast of the organ; round the cardiac orifice were four irregular patches of erosion, or fissures in the mucous membrane, involving partly the stomach, and partly the Œsophagus. About three inches above the cardiac orifice, on the left side, was a perfectly circular opening, three inches and a half in diameter, with slightly elevated edges, which were sharp and clean, as if cut with a punch. It bore a strong resemblance, on a small scale, to the perforating ulcer so frequently met with in the stomach. On the inner surface of the aorta, at the termination of the descending portion of the arch, nearly corresponding with the ulcer in the Œsophagus, but on a somewhat higher level, was an irregular opening, with ragged edges, formed by the projecting and torn lining membrane. At this spot, the coats of the artery were much thinner than elsewhere. About half an inch above was a patch of atheromatous deposit, the centre of which had advanced to calcification. The opening in the aorta, and that in the Œsophagus, communicated freely. The duodenum contained a loose coagulum, and the ileum and large intestine contained much semi-fluid blood. The jejunum was, however, empty. The other organs were apparently healthy.

STATE OF THE BLOOD AND THE BLOOD-VESSELS IN INFLAMMATION.

BY T. WHEARTON JONES, F.R.S.

The author affirmed that the inflammatory process was similar in warm and in cold-blooded animals; and that, with proper precautions, we might accept the information afforded by microscopic examination from both.

PRIMARY AND SECONDARY FIBRINOUS DEPOSITS. BY H. LEE, ESQ.

Mr. Lee divided deposits of fibrin into primary and secondary, and drew these general conclusions:—1. That the blood may, under certain circumstances, deposit from itself a fibro-albuminous element, either in some of the larger vessels of the body, or in the structure of internal organs. 2. That the process is not of an inflammatory character, and may occur either with or without the intervention of a membrane. 3. That the changes in the blood which immediately precede such an action may be caused by the admixture of vitiated secretions. 4. That the deposit, when formed, is capable of undergoing various changes, which issue in the formation of purulent-looking fluid, and is capable, during these changes, of communicating irritation to surrounding fluids.

TUESDAY, JUNE 28, 1853.

JAMES COPLAND, M.D., F.R.S., President, in the Chair.

ANALYTICAL EXAMINATION OF ALL THE CASES ADMITTED, DURING SIXTEEN YEARS, AT THE SMALL-POX AND VACCINATION HOSPITAL, LONDON; WITH A VIEW TO ILLUSTRATE THE PATHOLOGY OF SMALL-POX, AND THE PROTECTIVE INFLUENCE OF VACCINATION. BY J. F. MARSON, RESIDENT SURGEON TO THE SMALL-POX AND VACCINATION HOSPITAL, LONDON. (COMMUNICATED BY DR. CHOWNE.)

During the period comprised within this analysis, small-pox had been epidemic four times—in 1838, 1844, 1848, 1851; and rather more than half of the patients admitted into the hospital had been previously vaccinated. The analysis referred principally to the following points:—

- I. Natural small-pox.
- II. Small-pox after small-pox.
 - a. After natural small-pox.
 - b. After inoculation.
- III. Small-pox after vaccination.
 - a. Number of cicatrices.
 - b. Character of cicatrices.
 - c. Vaccinated, but without cicatrices.
- IV. Febrile eruptive diseases mistaken for small-pox.

A remarkable difference was observed between the vaccinated and unvaccinated patients, and also between the vaccinated cases themselves; some patients having the small-pox in a mild form, wholly devoid of danger, whilst others had it in great severity, scarcely, if at all, lessened by the previous vaccination. The author thought that the causes of this remarkable difference might be sought for among the antecedents in respect to the vaccination of each individual admitted, with a view to explain the extreme mildness of some cases,—the danger, unmitigated course, and even death, of others. Small-pox, in the unprotected, remains as virulent as it ever was. Vaccination, when performed in infancy, affords almost complete security against the fatality of small-pox, up to the period of puberty; and the general experience of the Small-Pox Hospital shows that small-pox did not usually occur after vaccination, until several years had elapsed. The most trustworthy evidence of the perfection of vaccination was to be obtained from the cicatrices.

The analytical series consisted of six tables. Observations on the results accompanied each table; and it appeared that 3,094 patients with small-pox reported themselves to have been vaccinated at some period of their lives. 1,357 had one vaccine cicatrix; and of these, four and a quarter per cent. died with a good cicatrix, and twelve per cent. with an indifferent cicatrix: mean, seven and a half per cent. 888 had two cicatrices; two and a half per cent. died with good cicatrices, seven and a quarter with indifferent cicatrices: mean mortality, four per cent. and a fraction. 274 patients had three cicatrices: average mortality, one and three-quarters. 268 patients had four cicatrices; and there died with good cicatrices under one per cent.; with indifferent cicatrices, none, the average being only three-fourths of one per cent. The author described a good vaccine cicatrix as distinct, foveated, dotted or indented, in some instances radiated, and having a well, or tolerably well, defined edge: an indifferent cicatrix as indistinct, smooth, without indentation, and with an irregular edge. The author's opportunities of examining the foreigners admitted with small-pox at the hospital, and comparing them with each other, and with the same class of persons in this country, had led him to the conclusion that vaccination was performed in the best manner generally by the Danes, Swedes, Norwegians, and Germans. Then came the Italians; and, from the few he had seen, the Spaniards; then the Scotch; then the Irish; and, lastly, the English and French. There must exist some grave and lamentable evils (more especially affecting the humbler classes) connected with the circumstances under which vaccination in country districts was performed. There could be no justifiable reason why the rural inhabitants of England and Wales should be less well vaccinated than the rural inhabitants of Denmark, Sweden, and Prussia. The mortality, severe as it was between the indifferently and the well vaccinated, was not the only evil result of bad vaccination. Proportionate to the mortality was the severity of the disease; and, to those who escaped death, there was damaged health, disfigurement for life perhaps, and undeserved discredit was brought on vaccination. Great judgment and caution should be exercised in the selection of vaccine lymph. Lymph for use was in its best state on the seventh day of the progress of the vesicle, the day week from the vaccination.

The author's conclusions were—

1st. That natural small-pox destroyed about one-third of all whom it attacked.

2nd. That small-pox after small-pox was of comparatively rare occurrence; that a second attack of natural small-pox was rare, but not often fatal, and that protection seemed to be the law. That after inoculated small-pox, an attack of small-pox had more frequently led to fatal results; but there is reason to presume that the virus used for inoculation, like a great deal of the lymph used at the present day for vaccination, was often taken at too advanced a period of the disease, and thus did not afford the full measure of protection it was capable of affording if taken at a proper time.

3rd. That vaccination performed in infancy afforded almost complete protection against the fatality of small-pox, to the period of puberty; that a variety of circumstances conspired to make it almost impossible to ascertain exactly in what proportion to the vaccinated cases of small-pox subsequently occurred, or might occur, if all persons lived to an advanced age.

4th. That as a matter of safety, it would be well for all persons who were vaccinated in infancy to be revaccinated at puberty; this measure being more especially requisite for those who were either indifferently or doubtfully vaccinated in infancy, and still more necessary for those who, though vaccinated, had no cicatrix remaining. Finally, as a matter of precaution, it would be desirable that all persons should be re-vaccinated, on small-pox existing in the house where they were residing.

Mr. STREETER would suggest the necessity of attending to the health of the skin before vaccination was performed. He believed that the exhausted state of the skin in tropical climates was one cause of the imperfect vaccination in them. About thirty years ago, in the practice with which he was connected, out of more than a hundred children who had been vaccinated, not one half returned to show the arm and the effects of the operation. He had only seen one fatal case of small-pox after vaccination, on the fifth day. He alluded to one source of danger in cases of small-pox—namely, a profuse flow of the catamenia, which occasionally occurred in the secondary fever.

Dr. WEBSTER entirely concurred with the opinion stated, respecting the great fatality of small-pox among young people, compared with those in more advanced life. For instance, during 1847, when upwards of 4,200 persons died by variola throughout England and Wales, more than three-fourths were under five years of age—the sexes being equally divided; while very few had passed their forty-fifth year. Again, the fact that death very rarely occurred in cases where the individual had been properly vaccinated in three or four places at the same time, was likewise most important, and showed, if the system was once properly imbued with true vaccine virus, little danger of subsequent small-pox need be apprehended. In his (Dr. Webster's) opinion, many of the deaths reported from variola, after cow-pox, occurred where the party never had been correctly vaccinated, especially throughout rural districts and country towns, where numbers remain unprotected, owing to the prejudices prevailing in ignorant minds against vaccination, who obstinately object to the operation, "as an impious attempt to arrest the will of the Almighty."

Dr. CHOWNE, having been a frequent visitor at the Small-Pox Hospital, could corroborate many of the statements made in the paper. The fact mentioned in the paper, of the number of persons affected with small-pox after vaccination in the country, was most important. The failure of vaccination in country districts was most lamentable; but it was not the fault of the practitioners—it was the fault of the Boards of Guardians, of the Government, by whom no efficient arrangements for vaccination were made, and consequently thousands lost their lives.

Mr. MARSON said that, much of his paper being tabular, it could not be heard before the Society. He wished, however, just briefly to allude to the number and quality of cicatrices. The difference observed was remarkable. Thus, amongst the persons who had only been vaccinated in one place, and the cicatrix was imperfect, twenty per cent. took the small-pox; whereas, when there were four cicatrices, and these were good, the number who took small-pox after vaccination was only one per cent. The medical public had relied upon the circumstance of Jenner having at one time vaccinated in only one place; but he (Mr. Marson) knew that Jenner did not confine himself to one, for he had seen a patient whom Jenner had vaccinated in 1806, and the person had four cicatrices.

ON INTERMITTING DIABETES, AND ON THE DIABETES OF OLD AGE. BY H. B. JONES, M.D., F.R.S., PHYSICIAN TO ST. GEORGE'S HOSPITAL.

THE author's object was to point out some phenomena connected with diabetes, which he had not found mentioned by other writers.

He offered some observations on the incorrect results obtained by calculating the amount of sugar present in the urine from the specific gravity. If diabetic urines were solutions of nothing but sugar in distilled water, the tables by Dr. Henry, and the amount of sugar calculated from the specific gravity, would give all the information required; but a multitude of other substances were present besides sugar, each of which was variable, and each of which might cause the specific gravity to vary, whilst the quantity of sugar might remain constant. The amount of sugar should always be determined by direct experiment.

On the subject of intermitting diabetes, there could be little doubt that our knowledge of the nature of this disorder might be extended by accurate determination of the varieties in the amount of sugar in the urine, passed at different periods of the day, and under different circumstances. His object was to record cases in which, either from the medical treatment, or the regimen, or the natural course of the complaint, the variation in the amount of sugar was from highly saccharine urine to total absence of sugar. In intermitting diabetes, the disease might be seen beginning and ending; and the explanation of the state of the urine which preceded the appearance of the sugar, and followed its disappearance, must be included in the true theory of diabetes. The records of seven cases of the intermitting form of the disease were given, and very minute particulars in several, illustrating the amount of sugar present in the urine at stated intervals in the twenty-four hours, as well as the influence of particular forms of diet on the proportion of sugar excreted. A remarkable excess of urea was constantly found before and after the sugar disappeared; and, although this might be attributed to animal diet, yet the occurrence of free uric acid and oxalate of lime in the urine pointed most clearly to a state of indigestion, which was every day found without any sugar appearing in the urine.

The author offered the following theoretical contrast between ordinary and saccharine indigestion. Ordinary indigestion showed itself in a want of action on the sugar and starch taken as food, in consequence of which excessive acidity was produced—that is, the changes in the non-nitrogenous food were imperfect. Imperfect changes also occurred in the nitrogenous food; this was made evident by an excess of urates and urea in the urine, and perhaps also by the formation of oxalate of lime. In diabetic indigestion, the effect might be traced also on the two great classes of food. At first, from the non-nitrogenous food, sugar was formed instead of acid. Ultimately, if not simultaneously, sometimes the arrest of healthy changes extended to the albuminous food; and, instead of an excess of urates and urea, other products were formed, one of which was sugar. Possibly benzoic acid, which is present in some cases of diabetes, in variable quantities, might be one of the new products. Whether this theory were true or not, it was of practical importance to remark the tendency to acidity in these cases of intermitting diabetes. In such cases, animal diet alone, or with alkalies, might stop the formation of sugar. It followed also that, when oxalate of lime, uric acid, and excess of urea, were found in the urine, it was probable that the diabetes might be temporarily, if not permanently, removed. The second part of the communication related to the frequency of diabetes in old age. M. Dechambre concluded, from observations made on the urine of old people at the Salpêtrière, that sugar was habitually present in the urine of old people. The author gave the particulars of nine cases of diabetes in elderly people, and thought that its occurrence at the latter periods of life pointed to the theory of diabetes as an indigestion resulting from an arrest of healthy changes in the food. The cases mentioned were, in the opinion of the author, opposed to the view of diabetes depending upon an affection of the nerves or of the liver; and his observation led him rather to the view of Dr. Prout, that diabetes was an indigestion, and that it first affected the non-nitrogenous, and afterwards the nitrogenous constituents of food. As regarded treatment, whatever was beneficial for excessive acidity, was found equally serviceable in diabetes. Alkalies were used in all the cases with benefit. Small meals, free from sugar and acid, and the substances that could give rise to them, formed the best diet. Vegetable acids with alkalies were also occasionally useful.

The author mentioned some experiments, determining the quantity of sugar in several kinds of beer and wine. Porter contained from 27 to 57 grains of sugar in each ounce of liquid; ale from 43 to 50 grains; beer 25 to 40 grains; port wine 8.5 to 11 grains; sherry 2 to 4.7 grains; claret none. The absence of all sugar, and the presence of a little alcohol, caused claret to taste highly acid, while the quantity absolutely present was not more, sometimes less, than in other wines which have no acid taste, as, for example, most port wine.

AN ACCOUNT OF A DISSECTION OF AN OVARIAN CYST WHICH CONTAINED BRAIN. BY HENRY GRAY, ESQ., F.R.S.

The patient was a female, aged 28, who died in St. George's Hospital of typhus fever. The vagina was healthy; the uterus was somewhat larger than natural, and its muscular wall thickened. The membrane lining its cavity was covered throughout its entire extent with a highly vascular villous membrane, resembling the decidua. The round ligaments were both healthy; the right Fallopian tube more dilatable than natural, and contained a thin bloody fluid; the right ovary was healthy; the left Fallopian tube was healthy. The left ovary was occupied as a large cyst, the size of an orange; the lining membrane of the interior of the cyst was vascular; its wall was composed of an external peritoneal layer, an inner, smooth, shining coat, devoid of epithelium. The cavity of the cyst contained a few short, light-brown hairs. The lower half of the tumour consisted of a second cyst, containing some yellowish, white, purulent looking fluid, with some granular fatty matter of the consistence of honey, scaly epithelium, and fine hairs of a brownish colour being intermixed with it. The fatty matter was found to be fluid at less than the natural temperature of the body. The hair, on being separated from the matter, was found to be attached to the wall of the cyst by distinct bulbs. A portion of the wall at the lower part of the cyst presented an appearance similar to the surface of the scalp; there was a thick layer of scaly epithelium mixed with fat covering the surface; numerous sebaceous glands were indented into this layer, and a canine tooth projected from the skin, fully formed; it was implanted into a fragment of bone, covered with periosteum. There was a third cyst situated near the fragment of bone, about the size of a walnut, the wall of which was delicately vascular, forming meshes resembling the pia mater; the contents of this cyst presented all the characters of brain. On microscopic examination, the ordinary elements of nervous matter were seen, consisting of varicose nerve tubules, intermixed with the elementary component parts of grey matter; nuclei, and nucleated vesicles containing granules. There was also a fifth cyst, the contents of which were much less like brain matter than the contiguous one. So far as the author had been able to ascertain, he believed that nervous matter had not been previously described as forming a portion of the contents of these ovarian cysts.

ERYSIPELAS OF THE HEAD AND FACE AFTER CONTUSION AND LACERATION OF THE SCALP: HÆMORRHAGE FROM THE PRINCIPAL BRANCHES OF THE RIGHT CAROTID ARTERY: LIGATURE OF THE VESSEL: RECOVERY. BY EVAN THOMAS, ESQ., M.R.C.S., RESIDENT-SURGEON TO THE WORKHOUSE IN MANCHESTER; ASSOCIATE OF KING'S COLLEGE, LONDON.

The hæmorrhage came from a wound in the temple, made for the evacuation of matter. Pressure proving unavailing, the common carotid artery was tied in the usual way, above the anterior belly of the omo-hyoid muscle. Some inflammatory symptoms occurred, referrible to the chest, but the patient recovered in the course of from two to three months.

FALSE ANEURISM OF THE POSTERIOR TIBIAL ARTERY (FROM A WOUND IN DIVIDING THE POSTERIOR TIBIAL TENDON IN THE OPERATION FOR CLUB-FOOT), SUCCESSFULLY TREATED BY INJECTIONS OF PERCHLORIDE OF IRON INTO THE SPURIOUS ANEURISMAL SAC. BY WILLIAM ADAMS, F.R.C.S., ASSISTANT-SURGEON TO THE ROYAL ORTHOPEDIC HOSPITAL.

The injection of perchloride of iron caused coagulation of the blood in the spurious aneurismal sac, produced by division of the posterior tibial artery in a child aged four weeks. The firm clot squeezed out the serum, which was seen oozing from the surface of the wound. The instrument used for injection was a glass syringe, with a long and slender tube, which was made to penetrate the clot, and convey the perchloride to the fluid blood.

ADDITIONAL EXPERIMENTS ON THE EXCITABILITY OF PARALYSED AND HEALTHY LIMBS BY THE GALVANIC CURRENT. BY R. B. TODD, M.D., F.R.S.

In the summer of 1847, Dr. Todd submitted to the Society the results of experiments tried with the view of testing the accuracy of Dr. M. Hall's dogma, that limbs paralysed by lesion of the brain became more excitable than the healthy ones by the galvanic current, in consequence of an increased irritability of the paralysed muscles. The present communication comprises the results of experiments to determine the difference on the influence of the current according to its direction, and also to ascertain whether any real difference of physiological effect exists when the galvanic trough, or the magnetic-electric or

electro-dynamic machine, is used. Thirteen healthy individuals were subjected to experiment, and with the following results:—

1st. That the obvious physiological effect was produced only on completing, or on interrupting, the galvanic circuit.

2nd. That more vigorous contractions were excited on the completion than on the interruption of the circuit.

3rd. That the completion or the interruption of the direct current produced more vigorous contractions than the completion or interruption of the inverse current.

These experiments were made with a Cruickshank's battery, charged with very dilute sulphuric acid. The magneto-electric rotation instrument and the coil machine (electro-dynamic) were afterwards used, and it was found that the same effects precisely were produced, and the same variation in the intensity of the contractions according as the current was direct or inverse. Fifteen cases of hemiplegic paralysis, caused by lesion of the brain, are afterwards detailed. The results of the galvanic experiments on these cases were as follow:—

1st. That of the fifteen cases, in only three was there any approach to a greater excitability of the paralysed than of the sound limb, and that in two of these it was manifested only under the influence of the inverse current.

2nd. That in three of the cases both the coil machine and the battery were used, and with precisely the same results; and that, in one of the cases, the coil machine alone was used, and with a result which corresponded with those obtained in similar cases by the galvanic battery.

3rd. That in each of the three cases in which a greater excitability existed in the paralytic limbs, the paralytic lesion in the brain was more or less of an irritative kind. In one case, the irritation was probably connected with an incipient process of cicatrization.

4th. That in many of the experiments all degrees of galvanic power were used, and with no other difference than that of degree; the amount of physiological effect being exactly proportionate to the power of the galvanic stimulus.

STATISTICAL REPORT OF FATAL CASES OF DISEASES OF THE BRAIN OCCURRING DURING THE LAST FOUR YEARS AT ST. GEORGE'S HOSPITAL. BY A. W. BARCLAY, M.D., MEDICAL REGISTRAR.

The report was confined to cases in which, by *post mortem* examination, the nature of the lesion was ascertained; and no reference was made to the proportion of cases admitted into the hospital, nor to the relative proportion of deaths and recoveries among persons supposed to be labouring under similar diseases. The cases were divided into—scrofulous inflammation, with or without actual presence of tubercles in the brain; simple inflammation; abscess; softening, of a non-inflammatory nature; delirium tremens; apoplexy, and tumours.

1. SCROFULOUS INFLAMMATION. These cases were 28 in number, and the age at which such cases proved fatal contrasted remarkably with other diseases of the brain. There were 9 under 15 years; 5 from 15 to 20; 7 from 20 to 25; 4 from 25 to 30; 2 from 30 to 40; 1 from 40 to 50; 1 over 50 years of age. No facts were recorded in the majority of the cases which threw any light upon the usual exciting cause of scrofulous inflammation of the brain. The symptoms were sometimes slowly and insidiously developed, at other times setting in with unexpected violence; while no point in the history of the case could be learned in any way accounting for their origin. This had frequently been the case when the patient was under observation at the commencement of the disorder. In 19 of the 28 cases, scrofulous or miliary tubercles were found in the brain or its envelopes, the proportion of yellow, cheesy, or scrofulous tubercle being far greater than those of the miliary kind. The mode of incursion of this form of brain disease was very various; but those in which it was most difficult to recognise it were the cases commencing with symptoms resembling ordinary continued fever. In three instances there had been previous attacks referable to the nervous centres; in another instance the symptoms were developed soon after a fall; in one, after exposure to the sun; in the remainder there was no satisfactory history. In 11 cases pain in the head was the earliest symptom; in 6, delirium was the first prominent symptom; in 2, convulsions commenced as the first evidence of mischief. In 11 out of 28 cases, pain of the head was not complained of; delirium was absent in 8 cases of this class. Convulsions may be said to be the rule, and their absence the exception, in childhood. Among the 28 cases there was no exception to this under the age of 13. The period at which delirium commenced, convulsions, paralysis, partial or general strabismus, were also carefully noted and recorded. The *post mortem* con-

dition of the cerebral mass, as well as of the membranes and vessels accompanying the scrofulous deposit, were next compared.

2. SIMPLE INFLAMMATION AND CONGESTION. The ages of these patients formed a contrast to those of the preceding class. Here the earliest period of fatal inflammation was 16 years, and only 5 were reported under the 27th year,—the period at which all but 5 of the scrofulous cases had terminated. Classed in periods of 10 years, there were 3 cases from 15 to 25, 8 from 25 to 35, 4 from 35 to 45, 3 over 45 years of age; the oldest occurring at the age of 57. Of the 18 cases, only 4 were of the female sex. The mode of incursion was less insidious, and more commonly traceable to a distinct exciting cause, than in the preceding class; and there were only three instances recorded in which the history of the case, and the character of the symptoms, rendered the diagnosis of acute disease in the brain by any means doubtful. The special symptoms characteristic of cerebral lesion, pain of the head, delirium, convulsions, and paralysis, were noticed in relation to their frequency, and the period of their occurrence. Of the *post mortem* appearances, lymph, or turbid serum, was found in 9 cases upon or under the arachnoid; in 14 cases fluid was found in the ventricles. The brain was soft in 4 cases, 2 with increased vascularity, and 2 with a watery state of the brain. It was congested in 11 cases, and wet and pale in 8.

3. ABSCESS OF THE BRAIN. Five examples were recorded of this form of disease. The history was somewhat obscure, and the causes which determined this action in the cerebral lobes, and the period at which suppuration actually commenced, were uncertain. Four of the cases were encysted; 1 was simple abscess; 2 were associated with caries of the temporal bone; 1 with suppuration on both sides of the cranium, opposite to a sloughing wound of the integuments.

4. SOFTENING OF A NON-INFLAMMATORY KIND. Only one instance of this form of lesion was recorded. Its duration was five months; its progress was chiefly masked by the existence of hemiplegia, with indistinct articulation; the whole of the medullary substance on the left side was softened and diffuent; the brain appeared congested.

5. DELIRIUM TREMENS. Ten fatal cases of this disorder were recorded. They were all of the male sex. The ages varied from 29 to 54. Various diseased states of other organs were noted, which probably exercised an influence, more or less decided, in causing the cases to terminate fatally. The heart was diseased in 7 cases; the liver in 6; the kidney in 2. In 4 cases tubercles were found in the lungs; once recent; five times in the form of a cretaceous mass. The membranes of the brain were congested in 4 cases; an excess of fluid was found under the arachnoid in 8 cases. In 6 cases, the ventricles contained an excess of fluid. The substance of the brain was in the majority of cases "wet".

6. APOPLEXY. There were 14 cases of this disease: 9 males; 5 females. Seven cases from 40 to 50 years of age; three from 50 to 60; three from 60 to 70; one over 70 years. Atheroma of the arteries at the base of the brain existed in 7 cases; healthy in 5. The heart was distinctly hypertrophied in 7 cases; in all of these cases the kidneys were also diseased. The anatomical conditions in the brain were various: in one case, an old apoplectic clot under the arachnoid; in another case, turbid serum under this membrane; there was effusion of blood in this case, limited to two small clots in the third and fourth ventricles. In 3 cases there was a good deal of blood effused at the surface, with large clots in the substance of the brain. In 9 cases the clots occupied a central position with reference to the hemispheres. Distinct softening in the vicinity of the clot was found in 5 cases.

7. TUMOURS. Of these were 6 cases; 3 males, 3 females; ages varied from 24 to 49. Four were examples of encephaloid disease; two of encysted growths.

8. ANOMALOUS CASES. Two cases could not be referred to either of the preceding classes. There was no evidence of any anatomical lesion in the cerebral structures; while the symptoms during life were distinctly characteristic of brain disease. In one the kidneys were in a state of degeneration; but the author doubted if albuminuria ever produced paralysis of one side of the face, and strabismus, which preceded the stupor and coma, terminating fatally.

The author concluded by a general summary of the symptoms during life, in relation to the anatomical lesions recorded after death.

ASSOCIATION INTELLIGENCE.

TWENTY-FIRST ANNIVERSARY MEETING OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

[Held at Swansea, 10th and 11th August, 1853.]

WEDNESDAY.

THE members of the Association assembled at 10 o'clock, in the Nisi Prius Court of the Guildhall, by permission of the Worshipful the Mayor, J. J. Strick, Esq.

On the motion of Sir CHARLES HASTINGS, Dr. OGLE, Regius Professor of Medicine in Oxford, the Annual President of the Association, took the Chair. He briefly introduced, as his successor, Dr. GWYNNE BIRD.

PRESIDENT'S ADDRESS.

Dr. BIRD, on taking the Chair, said that in accordance with their will and pleasure, as agreed to at their former meeting, he stood there as their President. And first of all, he would take leave in the name of himself and professional brethren of the Principality of Wales, to bid them, as members of the Provincial Medical and Surgical Association, a most cordial welcome, and to offer them all their congratulations and thanks that they had selected Swansea as the place for holding the anniversary meeting of 1853. He assured the members that, whatever might be their short comings at Swansea in reference to the reception of the Association, it was the earnest wish of himself and his professional brethren to make its advent to this town both acceptable and agreeable to the members at large. In the next place, he begged to return his sincere and cordial thanks for the honour they had conferred on him by electing him President of this Association. It was an honour as beyond his expectation as it was beyond his merits. Nevertheless, he felt most grateful for the compliment paid him. He was well aware of the difficult position in which he was placed in having to follow so distinguished and accomplished a gentleman as Dr. Ogle—than whom, perhaps, they could not have a better President. But for himself, he would observe that he would endeavour to do the best he could; he must throw himself on their indulgence, and they must "take the will for the deed". Dr. Bird concluded by stating that, as there was much business to be disposed of, he would not trouble them with any additional observations, but proceed at once with the business of the day.

The Secretary read the following

REPORT OF COUNCIL.

"The Council of the Provincial Medical and Surgical Association, in meeting their brother associates for the twenty-first time, have much pleasure in stating the fact, that such has been the great increase of members in the Principality as to render it highly desirable that this general meeting should be held at Swansea, the capital of a vast mining district, and the centre of an industrious and prosperous population; where we can assemble but to witness the progress of medical science, and that peace, good will, and harmony, without which we have no security for the successful and honourable performance of our professional duties.

"Your Council are glad to have it in their power to state that there has been a considerable increase in the number of members since the last anniversary meeting.

"The number of members now on the list is 1853. When the assembly took place at Oxford, they were 1628. The increase consequently is 225. The members lost by death during the year, and who have resigned, and who have been removed from the list in consequence of their subscriptions being in arrear, amount altogether to 202. On the whole, we are induced to think that the list of members is more perfect than it has heretofore been, and fewer members are in arrear, although still £1093 are owing to the Association for subscriptions.

"Your Council can report favourably of the District Branches. They are generally in active operation. The South Wales Branch has been fully incorporated into our body since the last report, and many new members have been added from that district. The Metropolitan Branch has also been formed, and has been followed by the accession of several new members.

"FINANCE.—PUBLICATIONS. Since the first week in January, a Journal has been published weekly, and has been edited by Dr. J. Rose Cormack, of Putney. The name of the Journal has been altered, and instead of being called, as heretofore, the "Provincial Medical and Surgical Journal", it is now called "Association Medical Journal". This alteration of the name of

the Journal, and all the arrangements connected with its publication in London, have been carried out under the direction of the Committee specially appointed at Oxford.

"Your Council are not enabled to state very definitively what effect the alteration in the publications will have upon the finances. The weekly Journal has been published too short a time to justify any decided opinion; but, as the expenditure is now greater than at any former period of the existence of the Society, it is of the utmost importance that exertions should be made to augment the income. Members are still not sufficiently punctual in the payment of their subscriptions; but it is perfectly clear that the affairs of the Society cannot continue to flourish, nor the present expenditure be borne, unless the income be steadily increased. This we hope may be effected by the exertion of the present members bringing in recruits, and by a punctual payment of subscriptions by all the associates.

"Since the last anniversary, the nineteenth volume of the *Transactions* has been published, and a copy sent to every member whose subscription is not in arrear. The *Transactions* have always been a striking feature in the proceedings of the Society, and your Council therefore feel much regret in announcing that in all probability they will not be continued. The resolution of the last anniversary, to publish a weekly Journal, will necessitate so large an expenditure on that account, as to leave little room to hope that a surplus will be left for the publication of *Transactions*.

"This, your Council think will appear, from a view of the cost of the Journal for the six first months of this year, which is as follows:—

	£.	s.	d.
Gross expenses of Journal for six months	1327	1	4½
From which is to be deducted			
For advertisements received	213	5	4
For advertisements due	190	0	0
For sales of Journal and subscriptions for non-members	48	0	10
		451	6 4
Net expenditure	876	15	2½
Making a yearly expenditure of nearly	1800	0	0

TREASURER'S ACCOUNT.

The Treasurer's cash account is as follows:—

	£.	s.	d.
<i>Receipts.</i>			
Balance in hand	92	14	1½
Subscriptions	1785	5	5
Sale of "Transactions" and Journals	52	19	0
Advertisements:—Provincial Journal	165	6	7
" Association Journal	213	5	4
	2309	10	6½

Expenditure.

Transactions and General Printing Account	338	12	11
Provincial Journal	624	15	10
Association Journal	927	18	1½
Salary of Secretary	105	0	0
Medical Bill Committee	200	0	0
District Branches	39	14	7
Anniversary Expenses	37	14	6
Sundries	42	1	9
Balance	8	12	9
	2309	10	5½

N.B. These accounts are made up to July 31st.

ASSETS AND LIABILITIES.

<i>Assets.</i>			
Subscriptions due	1098	0	0
Due for Advertisements, Transactions, and Journals on hand	237	4	1
	1330	4	1
<i>Liabilities.</i>

Balance	951	19	8

"MEDICAL REFORM. On the subject of Medical Reform, great exertions have been made during the past year; and the Committee appointed at the last meeting have been anxiously engaged in endeavouring to bring about some comprehensive

settlement of this intricate question; and your Council have much pleasure in stating that appearances are more promising than on any former occasion, as will appear by the following report, presented by the Chairman of the Committee to your Council.

"The first object of the Committee, after their appointment at Oxford, was to carefully examine the bill, and to make such alterations as their further experience, and the recorded opinions of the profession at large on the subject, dictated. Accordingly, on the 10th of November, an amended bill was published in the *Provincial Medical and Surgical Journal*; and the Committee afterwards proceeded again to communicate, in various ways, with the parties who were interested in the bill, and to endeavour to obtain from the medical corporations, both in England, Scotland, and Ireland, their sentiments with regard to the measure.

"These negotiations have been attended with encouraging results. With the Royal College of Physicians in London, their communications have been the most satisfactory. This ancient and learned body have held out to the Committee the right hand of fellowship; and, after the draft bill of the Association had been submitted to a Committee of Fellows, intimation was sent to the Association, through the Registrar of the College, that, if certain alterations were made in some of the clauses, which alterations were in no respect unreasonable, it was the opinion of the College that the bill would work harmoniously with the new charter which the College of Physicians are hoping to obtain from government.

"With the College of Surgeons, also, the Committee have negotiated; but the result has not been of so favourable a nature as with the College of Physicians.

"One of the greatest obstacles to the bill, in November last, was the opposition to it by the Scotch medical corporations; but, as there was a strong desire expressed by the medical profession in Scotland that some measure should be introduced as early as convenient into Parliament, a deputation was sent from the Association to Edinburgh; and the issue was most beneficial, as it ended, after a lengthened negotiation, in an agreement, on the part of the profession in Scotland, to support the general principles of the bill proposed by the Association.

"There was thus apparently a general unanimity in behalf of the bill; but, about this time, the Committee received intimation from the South Western Branch, that they entertained strong objections to some of the clauses of the bill. The Secretary of the Committee, in an interview with the members of the Council, at Exeter, endeavoured to remove these objections; but the alterations proposed have not satisfied these parties. They still require further amendment, which will be fairly considered, and, if thought desirable, adopted when the bill is before Parliament.

"Having thus produced a general good understanding in the profession relative to the bill, the attention of the Committee was directed to the government, and they determined to attempt to make an impression in that quarter in its favour. Accordingly, on the 18th of March, an interview was obtained with Lord Palmerston, the Secretary of State for the Home Department, to submit to him the bill, and to urge him to take it up as a government measure. In order to give greater effect to this deputation, the Presidents of the District Branches were requested to attend, and also about fifty members of the House of Commons; and, much to the satisfaction of the Committee, the President of the College of Physicians and the President of the College of Surgeons of Edinburgh came purposely from Scotland to accompany the deputation, and to express to Lord Palmerston their approval of the bill.

"Lord Palmerston received the deputation very courteously; and, after remarking that several unsuccessful attempts had been made on the subject, he said now that a great approach of unanimity in the profession had been made, as was evident from the importance and varied character of the deputation, he should give his best attention to the measure that had been laid before him; and, if there was a good prospect of bringing it to a satisfactory settlement—and he thought he saw now such an opportunity—he should feel it his duty to bring it before Parliament, in conjunction with his colleagues, as a government measure, and to carry it out with energy. His Lordship added, that he should communicate with the Secretary of the Committee, Mr. Hastings, on the subject.

"So matters rested until towards the end of April, when Mr. Hastings received a communication from the Home Office, stating that, if practicable, Lord Palmerston would bring in a bill this session.

"Knowing how much the pressure of business is felt in the
